W. H. D. D.

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, Author of the "English Flower Garden."

" You see, sweet maid, we marry
A gentler scion to the wildest stock;
And make conceive a bark of baser kind
By bud of nobler race: This is an art
Which does mend Nature,—change it rather: but
The art itself is nature."

Shakespeare.

VOL. LIV.—CHRISTMAS, 1898.

TO

THE REV. C. WOLLEY-DOD

THE FIFTY-FOURTH VOLUME OF "THE GARDEN"

is dedicated,

INDEX TO VOLUME LIV.

(Illustrations in Italics.)

A.

- Abelia uniflora, 400
 Abutilon Golden Fleecce, 92, 196; *insigne*, 432; Swatzi, 151; *vexillarium*, 400; *vitifolium*, 78
 Abutilons, 432
 Acacia Buchananii, 258; *microphylla*, 190
 Acalypha hispida, 190, 258, 520; *Mucfoeana*, 186; *Sanderiana*, 62
 Acalyphas, 44
 Acantholimon venustum, 72, 129
 Acantholimon, propagating, 346
 Acer Juhlkei variegatum, 249, 508; *Negundo elegans*, 210, 508; *platanoides* Schwedleri, 178
 Achimenes, 133
 Achineta Barkeri, 332; *Barkeri*, 332; *colossea*, 170
 Adiantum Farleyense, 401; *Faulkneri*, 249
 Aedides quinquevulnerum, 174; *suavissimum*, 236
 Aeschynanthus speciosus, 202
 Agapanthus umbellatus, 261
 Agathæa celestis, 519
 Ageratum Perle Bleu, 260
 Allium kansuense, 51
 Almond, the, and its varieties, 122
 Alocasia spectabilis, 311
 Aloe ciliaris, 539
 Alonsoa Warscewiczii compacta, 187
 Alstromeria inodora, 190; *pelegrina*, 218
 Alstromeria, 97
 Althæa tota alba, 249
Amaryllis, a seedling, 66; *Belladonna*, the Kew variety, 414; *Belladonna* (*Kew variety*) and the type, 414
Amaryllises, seedling, 66
 America, a note from, 72
 Amorpha canescens, 213
 Andromeda as pot plants, 476, 518
 Androsace lanuginosa, 251, 366, 404; *sarmentosa*, 128; *sarmentosa*, 128
 Anemone Halleri, 190; *japonica*, 349; *j. alba*, 112
 Anemones, Poppy, in an Irish garden, 126; *Poppy*, in an Irish garden, 126
 Angraecum articulatum, 377; *bilobum* Kirki, 404; *citratum*, 34; *sesquipedale*, 512
 Anguloa Ruckeri sanguinea, 2; *uniflora*, 175
 Anomatheca cruenta, 171, 204, 480, 499, 516
 Anthemis styriaca, 333; *styriaca*, 333; *tinctoria* (C. E. Buxton's variety), 387
 Anthurium Lawrenceæ, 186
 Antirrhinum Yellow Prince, 52
 Ants, 112; getting rid of, 122
 Apple Albury Park Nonsuch, 430; Allington Pippin, 255, 365; American Mother, 417, 439, 538; Ballinora Pippin, 438; Baumann's Red Reinette, 357; Beauty of Bath, 229, 430; Beauty of Stoke, 482; Belle de Pontoise, 430; Blenheim Orange, 179; *Blenheim Orange*, 179; Boston Russet, 48; Bramley's Seedling, 430, 501; Cellini on a wall, 363; Chelmsford Wonder, 430; Cornish Gilliflower, 439, 461; Cox's Pomona, 75; Crimson Queening, 75; Devonshire Quarrenden, 149; Duchess of Oldenburg, 256; Emperor Alexander, 148; *Empyror Alcaudor*, 148; French Crab, 503; Gooseberry, 535; Hambling's Seedling, 430; Invincible, 312; Irish Peach, 68; Kerry Pippin, 194; Langley Beauty, 179; Langley Pippin, 171; London Pearmain, 429; Lord Derby, 417; Maltster, 395, 458, 502, 537; Margil, 458; May Queen, 538; McIndoe's Russet, 430; Mrs. John Seden, 312; Newton Wonder, 430; Parker's Seedling, 179; Rambour Papelon, 430; Red Streak, 458; Reinette du Canada, 429; Ribston Pippin, 537; Royal Jubilee, 502; Scarlet Nonpareil, 194; Stirling Castle, 1; The Sandringham, 68, 430; Tyler's Kernel, 416, 538; Warner's King, 119; *Warner's King*, 119; Wealthy, 430; Yellow Ingestre, 227
 Apple crop in 1898, 21; culture near London, 120; the common Crab, in the shrubbery, 358; trees blighted, 2, 393

 Apples, too many varieties of, 483
 Apples which fruit on the points of their shoots, 483
 Apricot Large Early, 462; pests, 536
 Apricots, good, from seed, 194; planting young, 537; watering and feeding, 1
 Aquilegia Stuarti, 92
 Archways, hop-covered, 259
 Aristolochia lians, 191; *tricaudata*, 185
 Artichokes flowering, 382; Globe, 141; Jerusalem, disease in, 225, 303
 Arum italicum marmoratum, 297
 Arum Lilies resting, 475; turning yellow, 300, 352
 Arundinaria aristata, 89, 507; *auricoma*, 214; *metallica*, 89, 507; *nitida*, 89, 507; *Veitchi*, 89, 507
 Aselepias tuberosa, 159
 Asparagus beds, 142; beetle, the, 22; feeding, 224; growing, 383
 Asparagus Sprengeri, 88, 118
Asparagus Sprengeri, 88
 Asparagus Sprengeri compactus, 498, 540
 Asplenium divaricatum, 71; *ornatum*, 49
 Aster alpinus, 328, 348, 387; a. and slugs, 361; a. speciosus, 329; a. superbus, 329; *Amellus* bessarabicus, 278; A. Riverslea, 275; *cordifolius* Diana, 320; *Edith*, 297; F. W. Burbidge, 258; *grandiflorus*, 320, 400; John Wood, 272; *Madonna*, 275; *Mary Crum*, 319; *Novi-Angliæ roseus*, 298; *Novi-Belgii* Arcturus, 298; seedling from Arcturus, 319; *Tradescanti*, 400; *turbinellus*, 320, 365
 Aster, the Gerbe China, 271
 Astilbe Gerbe d'Argent, 151, 301; *Gerbe d'Argent*, 301; *Silver Sheaf*, 132; *Thunbergi*, 131
 August in S. Devon, 268
 Autumn tints, 411
 Autumn, wet, and pot Strawberries, 397
 Azalea indica alba, 487; *part of an*, at Crouch Grange, Warham, 487; J. J. de Vink, 507; *obtusata*, 507; *viscosa*, 406
Azaleas, *hurdy*, in a vase, 282; species of, 282
 Azaleodendron Edouard Andre, 507

B.

- Baden-Baden, notes from, 57, 276
 Balsams, 258
 Bamboo canes on walls, 502; stakes, 458; outdoors, endurance of, 380, 420
 Bamboos flowering out of doors, 232; in pots, 390
 Bambusa palmata at Glasnevin, 131
 Baptisia australis, 12
 Bean, the Florida Velvet, 392
 Beans, dwarf French, and red spider, 182; in pits in autumn, 328; French, forcing, 414, 419
 Beans, Broad, in pots, 477; late, 413
 Beans, late Runner, 489
 Beans, Runner, diseased, 212
 Bees and fruit, 162, 307, 379
 Bert and Carrot sowing, 162; Crimson Ball in summer, 46; Red Globe, 231; Globe-shaped, 382
 Beets, Globe, 224
 Begonia coccinea, 186, 231; *Corbeille de Feu*, 333; *Dregei*, 529; *echinocephala*, 231; *Fairy Queen*, 92; *Florence Nightingale*, 9, 31; *Gloire de Lorraine*, 67, 329, 324; *Haageana*, 439; *Knowsleyana*, 475; *metallica*, 362; *Moonlight*, 390, 433; *President Carnot*, 404, 518; *semperflorens*, double-flowered forms of, 352; *Thunderer*, 9; *venosa*, 499; *Winter Cheer*, 455; *Winter Perfection*, 398
 Begonias, double, 9, 40; endurance of, 199
 Begonias in the flower garden, 196; rust on, 192
 Belladonna Lily, the Kew, 414
 Belladonna Lilies at Kew, 276
 Bellflower, the Chimney, 132
 Benthamia fragifera, 310
Benthamia fragifera in a Devon garden, 310; in fruit, 104
 Birds, insects, 261, 323
 Blackberry growing, 358
 Blackberries, 255, 307; as a paying crop, 394
 Boccconia cordata, 279; *cordata*, 279; *Ferruginea*, 279; *microcarpa*, 196, 276; *microcarpa*, 279
 Boccconias, 279
 Bog garden, forming a, 346
 Bomarea Carleri, 480
 Books—
 "Alpine Plants in Lowland Gardens," 371

THE REV. C. WOLLEY=DOD.

Mr. Dod was born on the first day of spring, 1826, at Matlock, both his father and his mother being natives of Derbyshire. He has often complained of the many synonyms of garden plants, and of the frequent changes in their names made by botanists; but he should not forget that in doing this he is throwing stones at others from a glass house, as he himself had three synonyms, and has borne in succession three surnames. Till he was two years old his name was Hurt; then for forty years he bore his mother's name of Wolley, and in 1868 he took the name of Dod, being the surname of his wife's grandfather, of whose small estate at Edge he then became possessor. The Dods were probably aboriginal at Edge; at any rate, there was no historical record of their first settlement in the place when the Normans conquered the county of Chester and appropriated most of the land.

From his early childhood Mr. Dod has been devoted to the love of natural history in all its branches, and was formerly an enthusiastic collector of birds' eggs, birds' skins, and insects before he paid attention to plants; but he never studied the scientific classification either of animals or plants, being contented to learn by observation the habits and differences of the living things he saw. All his life he has suffered from weak eyesight, an infirmity which has increased with years, and he has never been able to read much or for long together; but his memory, which in boyhood was remarkably retentive, enabled him to get on with lessons at school better than many who were far more studious. Before he left Eton he could stand up when called upon in school and construe an ode of Horace, holding a sham book in his hand without incurring the usual penalty for having no book. Most of his play-time was then spent in fishing or collecting insects, and as soon as mid-day school was over he might be seen sallying forth, generally running, with a fishing-rod or a butterfly net, going to the river or to Windsor Great Park, where he spent much of his time. He once got into serious trouble for bringing to his private room, over one of the shops in Eton, some harmless snakes he had caught in the park, which escaped from the bandbox into which they had been put, and so alarmed the good man of the house, that he went at once to Mr. Dod's tutor and accused "Wolley minor" of attempting to get him and his family "stung to death in their beds."

After being for six years first a scholar, then a Fellow of King's College, Cambridge, Mr. Dod married in 1850, and was an assistant master at Eton for thirty years. At the beginning of 1879 he came to reside permanently at Edge. He there devoted a good deal of attention to the cultivation of alpine and other hardy plants, responding heartily to the movement then in progress for restoring those plants to their proper place in country gardens from which they had been ignominiously expelled. Since that time gardening has been with Mr. Dod a constant habit and amusement, and though he has many other occupations, he employs in this pursuit many intervals which might otherwise be passed in idleness, boasting that he is always to be found gardening when he is doing nothing else. "Having nothing to do" is a malady to which he has never been liable, and he has always said that of all the sufferers described by Virgil as punished for their crimes in the nether world, he felt the greatest compassion for the hero who, after an active life of energetic enterprise, was condemned to be idle for ever—

*Sedet aeternumque sedebit
Inferis Theseus.*

As for Mr. Dod's gardening tastes and the plants he grows in the very cold and unpromising clay soil of Edge, enough has been told from time to time in the pages of THE GARDEN to satisfy even those who are more fond of reading than the writer of this notice. He never sends a note on the cultivation of any plant which is not founded on his own experience. Mr. Dod boasts that there is not a plant in his garden which he has not planted with his own hand.

The GARDEN.

ORCHARD AND FRUIT GARDEN.

WATERING FRUIT BORDERS.

THERE can be no doubt that in the majority of cases fruit borders of all kinds, both inside and out, are insufficiently watered, and many failures may be traced to this cause alone. In fact, where the borders are properly made and drained it is difficult to overwater them by any reasonable means, especially outside borders under hot, dry walls. The surface of inside Vine, Peach, or other fruit borders is often deceiving, the syringing, damping down, and watering of plants in the house making the surface just moist, while below the soil is drier than it should be. Again, when water is given it is often with too sparing a hand, for nothing short of a thorough soaking of every particle of soil will do. In planting young Vines and fruit trees it is especially desirable that the borders be kept moist, though here, of course, one must not run to extremes. But, from a desire to avoid over-watering, I am sure many run into the opposite extreme and give too little. When one considers what a young Vine planted at the bottom requires to maintain the rapid growth we look for, it is obvious that the roots will soon be all over the border in search of moisture, so there is little fear of souring by giving them all the water they will take. The time-honoured custom of top-dressing newly-planted Vines with horse droppings, leaf-soil, and other materials that soon tread into a pasty, wet mass, is not the best that can be followed by any means. It clogs the passage of air and water and has always an untidy appearance, necessitating frequent renewals, with the attendant unpleasantness. Borders surfaced with burnt refuse give always a better indication of their state as regards moisture, and a short time after watering they can be raked over and all made tidy. A good deal of water is wasted by allowing borders inside and out to get dry and crack away from the walls. This is not sus-

pected often, and yet if the top 3 inches or less of the soil were removed it would be plain enough. The water of course rushes through at once to the drainage and is wasted, owing to the lower portion of the border being much drier than the upper. On outside borders a mulch of manure is beneficial, as it keeps the moisture in and does away with some trouble in watering. A great waste frequently occurs in watering with liquid manure, and not only is the valuable manurial property wasted, but the trees are actually injured. Some Peach trees in a neighbouring garden were weak and did not make a satisfactory growth, and the owner, having a quantity of house sewage, used it hardly diluted, with the result that the trees are now practically useless. Had the borders been well soaked first with clear water, then given a little of the manure highly diluted, much good would doubtless have resulted, but to give strong manure water to dry roots is a great mistake.

The watering of indoor Peach and Vine borders in winter is often neglected, with the result that the trees in spring start weakly and the Vines lack vigour. Outside trees seldom suffer to the same extent from bud-dropping as those under glass, while the former are worst after a dry season. Trees on hot, dry walls, with perhaps a vegetable crop growing to within a foot of their stems, are never so long-lived as others in more open and moist positions. All this points to the fact that root moisture, as a rule, is insufficiently provided, both in summer and winter, and has much to answer for in regard to insect attacks, weak growth, bud-dropping and other troubles of the fruit-grower. H. R.

Apple Stirling Castle.—This is one of those varieties of Apples which never seem to miss bearing, no matter what the season may be. I have trees of it some twenty-five years old which are equally as constant and prolific now as when they first came into bearing, and I cannot call to mind a season in which fruits of Stirling Castle

have been altogether absent from the shelves in the fruit room. Besides being a constant cropper, it is almost enormously productive, and unless the trees are relieved either by thinning when the fruits are quite small, or at the latest as soon as they begin to be of service, they make but little growth and assume a stunted appearance. Heavy crops should always be thinned, as both the size and quality of the fruits retained are considerably enhanced thereby, which is a great consideration when they have to be sent to market. It also pays to feed the trees, and once they come into full bearing feeding can hardly be overdone. This Apple becomes beautifully flushed with red in seasons when sunshine is abundant. It is an excellent cooker, and keeps in good condition up to Christmas in a cool store. The only drawback is the fact of the tree being liable to canker when worked on the Paradise stock. When worked on the Doucin stock I find it is free of this disease, and it also makes more free growth. Were I planting a fresh lot of trees I should most decidedly give those on this stock the preference. As a standard on the Crab it makes medium growth, but is quite as prolific as when grown in the form of a bush, and the fruits are as a rule highly coloured.—A. W.

Watering and feeding Apricots.—The time has arrived when the above should have attention—that is, if fruit of the best quality is wished for. Apricot trees require rather more water than Peaches to enable the fruits to lay on plenty of pulp and to become filled with an abundance of the rich luscious juice peculiar to the fruit. If water is not supplied liberally the flesh is apt to be tough instead of semi-melting, and juice is then also sadly deficient. To obtain size in the fruit it is necessary that the trees have assistance at the roots in the shape of manurial aids in addition to having free supplies of water. The latter should always be given in sufficient quantity to well moisten the border down to the drainage, and repeated as often as the subsoil tester gives indications that further supplies are required. Regarding the kind of stimulants to use, this will depend on circumstances, because if liquid manure is plentiful there will be no necessity to resort to artificials. In the absence of the former by all means use the latter, and in all cases see that the soil is moistened before apply-

ing them. To apply liquid or chemical manures of a quick acting nature, or such as become readily soluble, to a dry border is sheer waste, as they find their way into the drains before the roots of the trees have had time to benefit thereby. Another matter which should be attended to is loosening the surface of the alleys before watering, particularly if it is trodden hard. This will ensure a more even distribution of the water and allow of the whole area of the border becoming properly moistened. If necessary, apply a fresh mulch, or if this has been neglected, get it done as soon as watering is completed. The trees also greatly appreciate a washing, and if this can be done daily whenever the weather is fine, it greatly assists in keeping down earwigs and woodlice besides freshening up the foliage.—A. W.

Blighted Apple trees.—Many of the standard Apple trees hereabouts seem so badly attacked with blight and aphids, that they look as if scorched, the foliage being browned and falling. This is not confined to Apples only, for Oaks are similarly affected. The crop, where there was a prospect of one, cannot stand against such a check to the tree's growth, and next season's crops must be jeopardised by the same influences. Garden trees could be syringed with an insecticide or a petroleum emulsion, but large orchard standards cannot be so easily dealt with. The prospects are not nearly so favourable for a good Apple crop now as they were only a short time ago. Trees everywhere and of almost every kind flowered beautifully and the fruit appeared to have set freely. The aspect has changed considerably, although even now there are some sorts well furnished with fruit and free from insect attacks. Lord Suffield, London Pippin, and York-hire Greening are some of those most badly attacked. The heavy thunderstorms occurring at midsummer may have a good effect in dislodging many insects and clearing the trees of the soot-like mould which infests the leaves.—W. S., *Roof Ashton, Trowbridge.*

LAYERING STRAWBERRIES.

ROYAL SOVEREIGN is the earliest variety I grow and the first fruits have not ripened until to-day (June 21) in the open. This is later than usual, for I usually am able to gather all the best of the fruit before commencing to layer the runners for forcing and planting new quarters, whereas they are almost ready now to layer. It is, of course, a great advantage to have a reserve plot for supplying layers, but, unfortunately, most of us have to take them from the fruiting beds. For forcing it is the rule in many places to use the fruiting pots at first, but it is not the best way, especially during a wet season when the whole of the soil is soaked through by rains before the roots are half through it. Plants layered in small pots take up a good deal less room on the bed and do not cause much more trouble in watering in a dry season. In a wet one the advantages of the small pots are plainly seen by the better colour of the foliage. The subsequent repotting is, of course, a big undertaking where a large number of plants is forced, but it is not all loss even here, as the earlier work at a busy season is less with small pots. It is not often that an elaborate mixture can be prepared, nor is it necessary. Kitchen garden soil has to help out with the loam here at any rate, and it is rammed firmly into 3 inch and 4 inch pots. For a week or two beforehand this makes a job for wet days, and the pots can be stacked up closely and covered with old mats, when they will not dry up much. There is no need to drain the pots, but a lump of the more fibrous portions of the loam may be put in the bottom when filling them. On the bed a man and boy are needed, the latter to hand the pots and stones or pegs, while the man layers the runners. A man who is accustomed to the work does it very quickly, an important point being to see that the pots are stood level to receive water, while the closer they are arranged the better, as they keep moister, stand firmer, and

take up far less space, an advantage until the fruit is all gathered. The most frequent mistake in this mode of culture is leaving the young plants until they are badly potbound before re-potting, and once the roots get firmly coiled in small pots they are no better than unlayered runners, either for planting out or potting on for forcing. They should feel their pots, as it is termed, but after this the sooner they are potted or planted the better. H.

ORCHIDS.

NOTES ON ORCHIDS.

THE free-flowering nature of *Cymbidium Lowianum* and the fact that it carries its bloom-spikes for many weeks are apt, in the case of plants not in the most robust health, to lead to exhaustion. Rather than allow this the spikes should be cut after a fortnight or three weeks' flowering. On the other hand, strong, vigorous specimens carry their spikes with ease until the flowers begin to lose colour, when they may be cut and placed in water, where they last for a considerable time. The tall spikes look very pretty and natural arranged in a large bowl with foliage of *Arundo* conspicua. The flowering house has been very full during the past three months, but when midsummer is past the number of species and varieties in bloom begins to decrease. If anything approaching crowding has been allowed with such plants as *Cattleyas* or *Laelia purpurata*, these will need a little careful treatment now. Standing thickly, the light available has only reached one part of the plant, and as more shade is used than in the growing quarters this will also be felt, as well as a slight exhaustion consequent on flowering and a rather dry state of the atmosphere. If any are to be repotted they may with advantage go back to the growing quarters for a time to recuperate before disturbing them, and it is worthy of note that all such as *Cattleya Mossie*, some of the summer-flowering hybrids in this genus, and *Lelio-Cattleya* should after this date be encouraged as much as possible. Great care now is necessary in shading plants of the habit of *Promeneas*, *Paphinias* and others, that, though enjoying a good light at all times, are especially apt to be injured by bright sunlight. Compared with the majority of intermediate and warm house plants they need much more shade, simply because the foliage is thin in texture, lacking the leathery feel of that of *Cattleyas* or the hard surface of that of *Dendrobiums*. It is a sensitive class of leafage in fact, easily injured by extremes of sun or shade. These two after flowering will often need attention to the compost, the *Paphinias* especially being averse to anything sour or close about their roots. The roots are singularly large and fleshy, and to push through a hardened lump of peat is simply impossible. I like plenty of chopped *Sphagnum* Moss with these, as it does not sour easily and may be more readily removed than peat when it decays. Sound fibrous loam, too, of that soft yet tough character termed "silky," is a very useful addition to the compost and may be used in equal proportions with the materials named, plenty of crocks being added to facilitate the passage of air and water.

Dendrobiums, despite the cold, unseasonable weather recently experienced, are making good progress, and I am more and more inclining to the opinion that a fairly cool regime at first, changing to more heat as autumn draws near, is what these Orchids delight in. A close and stuffy atmosphere at first causes a weak growth, but open the houses at 6 o'clock in the morning and let the temperature rise naturally and

gradually, at the same time keeping abundance of moisture in the air, and growth of the right sort—hardened as it is evolved—will result. Insects, too, will be conspicuously absent, and this at least is a step in the right direction. Those having many short stem-like pseudo-bulbs, in the way of *D. pulchellum* or *D. Falconeri*, and the more recent *D. Victoria Regina*, should by now have made some progress and will soon be rooting. If not already done, the compost should be seen to, allowing a bit of sweet, new material about the bases of the stems. If any require potting, it is those, like *D. superbum*, that flower later than the usual run, and have besides a long pseudo-bulb or stem to make up. The smaller-growing section of *Oncidium* from the West Indies, such as *O. pulchellum* and *O. tetrapetalum*, are often neglected now, and this, with a naturally weak constitution, has led them to be considered even more difficult of cultivation than they really are. If more care were taken to prevent checks by draughts and loss of atmospheric moisture—if, in fact, they were kept drier at the root and in a more regular atmosphere—they would certainly be more satisfactory, and, as is well known, they are very beautiful. It has been necessary to use much more fire-heat than usual, and even in the cool house in the latter part of May and beginning of June it was necessary to have a little warmth in the pipes. But now that more seasonable weather is with us the usual summer treatment will be practised, i.e., heavy shading and free ventilation on warm, moist nights, with abundance of atmospheric moisture that settles upon the plants in the shape of dew. In all the other departments a full growing temperature will be maintained, the Mexican house running up well with sun-heat tempered by abundant moisture at the roots and in the atmosphere, most of the *Laelia* species grown therein being quite unshaded. H.

Anguloa Ruckeri sanguinea.—The blossoms of this species are very richly coloured, the inside of the segments especially, being of a deep blood-red, against which the pale column and lip show up rather conspicuously. It is a free-flowering and easily-grown plant, though with possibly a little less vigour than the type, and may be cultivated in an intermediate house. A fairly good compost may be allowed, a proportion of good loam being of great assistance. Water freely during the summer, and in winter give just enough to keep the pseudo-bulbs plump. It is a native of Colombia, and was first imported many years ago by Messrs. Rollisson, of Tooting.

Lycaste costata.—The large and handsome flowers of this *Lycaste* are among the finest in the genus, and the plant, moreover, has an imposing appearance when healthy. The pseudo-bulbs are each 3 inches or more high, bearing large, handsome foliage. The flower-spikes are shorter, the whole flower white, with a prettily fimbriated lip. A native of the Peruvian Andes, it thrives well in the cool house, where it may be grown in equal parts each of loam fibre, peat, and chopped *Sphagnum*, a good sprinkling of rough crocks and charcoal being mixed or laid in when potting. The drainage must be good, as when growing freely the plants take a lot of water. It was introduced in 1854.

Maxillaria Sanderiana.—A good form of this fine species comes from "J. R.," the flower of the usual size and, if possible, deeper in the colour of the spots at the lip and in the petals. Although it may do as well in other positions, I have lately noted some remarkably fine plants grown in a much warmer house than usual. I never like placing these Andean Orchids in heat, for they are singularly subject to insect attacks there, and although it is true thrips can be much

more easily kept under than formerly, no doubt it is a weakened condition of the plants in the first instance that induces the attack. For this reason the plants are safest in a cooler house, progress here being more likely to be steady and maintained. At the same time I believe this species will start more freely and produce more flowers if the temperature in winter is not allowed to go below 50°. In a dark house and a low temperature in winter the plants sicken, but if grown in baskets well up to the light and the air kept moving about them they will be satisfactory. It was introduced by Messrs. Sander in 1884.—H.

Cattleya gigas. This is certainly one of the finest of the labiate Cattleyas, and a welcome addition to the plants in flower. Many fine varieties exist, but it is certainly less variable than most species. No matter how this species is treated as to watering, temperature, or other details, there will always be individual plants growing out of season, and this leads to its flowering at various times of the year, and not keeping so closely to a stated period as is usual with *C. Mossiae*, *C. Trianae*, and others of this class. Provided they flower upon the unseasonable growth it matters little—indeed, it has the advantage of prolonging the flowering season; but though many successful growers manage to induce their plants to do so, it is not, unfortunately, always the case, and this points to the advisability of keeping them dormant if possible in autumn, and also that of thoroughly ripening the growth, for without a doubt a well-ripened pseudobulb is far more likely to push a flowering growth than one that has been grown in dense shade. Among the plants I have, one of a fine type of *imperialis* always makes two growths a year, and though the autumn-made set never produces a flower, that made in spring never fails to bloom strongly and well.—H.

FLOWER GARDEN.

THE DOUBLE POET'S NARCISSUS.

I TAKE it when your correspondent "Dorset" enquired as to the behaviour of the Gardenia-flowered Narcissus recently in the pages of THE GARDEN, he had in mind its behaviour in British gardens and British soils. The quantity found upon the markets is but little guide in the matter, as the flowers can be packed when fully expanded with but little damage. Furthermore, they may be—and are—sent in large quantities in the expanding stages often long distances, as I know full well from personal experience, to be opened in water under glass and much nearer London. There is a twofold advantage in this, the bulbs being grown in a soil and climate more generally favourable to their well-being than our own, and possibly also where land and labour are much cheaper. Then again, carriage is greatly reduced, and this, with the enhanced purity of the flowers when opened in the manner above noted, renders them far more useful than those grown entirely in the open ground. In the above manner quantities come from a long distance, and the market supply should not act as a guide in respect to this Narcissus flowering generally in the British Isles this year. At the same time there is proof from widely different, though equally reliable, sources that this valuable and late kind has been giving of its useful flowers in greater numbers this spring than is its wont, even after producing evidence earlier that the flowering scapes were present in considerable numbers, a fact which is most perplexing when finally the very large majority are affected with the so-called "blindness." With freer flowering this spring many will anxiously desire to know the reason, the more so because it is obvious from

inquiries, as much as from opinions already given in the gardening press, that this valuable double white Narcissus is behaving well this year, irrespective of the soil, the position and likewise the locality in which the plants are growing. From my own inquiries I am able to state it is flowering quite near to London and on heavy soils, again in other places where the soil is very sandy and fine, again where but a thin layer of poor soil covers the chalk that is below, and again where a light loam overlies gravel of several feet in thickness. That it should flower so well in all these descriptions of soils would appear to place soil in a secondary position, at least in some respects. And for the general success of the crop of flowers we must, I think, look to the season, the congenial conditions of the weather in particular, and more especially to the moisture-laden warmth during the nascent period of the petals. Many who have had a good crop of flowers this year have added nothing to their usual cultural routine to produce it, and these at least must look beyond culture for the cause, inasmuch as the heavy mulch of manure given each year has not always produced a result similar to that experienced this year. But the food thus supplied has certainly not been thrown away, rather has it gone to storing up greater supplies of energy and vigour in the plant, for, perhaps, no Narcissus is so capable—and with benefit to itself—of assimilating rich food supplies as is this one. This is a fact that should not be lost sight of in planting. There is also a tendency to perpetual root action, peculiar to several others of this section, and this may in some degree account for its semi-voracious habit. One point in the culture of this variety, to which I have in past years given some prominence, is the necessity for having the bulbs thoroughly established before flowering can at all be expected, and, in making inquiries recently, it is significant that the bulbs are well established in their places in each and every instance—some two, and others three years, one case even more than this. Under these circumstances I should be glad to know if any reader of THE GARDEN has secured a good bloom from bulbs planted during the autumn of last year. That it should be essential with one kind out of the great army of Narcissus to get it thoroughly established before its flowering can under any circumstances be depended upon, is something so foreign to the family as a whole, as to make it worth recording. The primary conditions to success are to plant rather deeply—8 inches at least where the soil permits—very rich soil and one of a heavy nature preferred, and to avoid disturbance at the root. After the second year a good winter mulch should be given each season.

Touching the food supply and its value upon the variety in question, I am enabled to give some very valuable and instructive information gathered in a conversation with the Rev. G. H. Engleheart quite recently. It is instructive because it proves the value of the mulch in certain conditions of soil, for while Mr. Engleheart produces not only the most graceful and beautiful flowers of the whole genus, together with flowers of the very largest size, it will surprise not a few to know that the staple soil of Mr. Engleheart's garden is poor and hungry—a very thin layer indeed overlying, I believe, the chalk subsoil. In a portion of this garden Mr. Engleheart has a bed of several hundreds of the above kind which have produced really grand flowers this year, and to an extent hardly, if ever, before known. The flowers are of the finest possible description, and their excellence is attributed in no small

degree to the system of mulching with bonemeal to a large extent. In this case also the bulbs are well established. A portion of this rather extensive lot extends to the rooting boundary of a large Horse Chestnut, and in describing the difference Mr. Engleheart observed it was easy to define the limits to which the roots absorbed the food supplies from the Narcissus bed almost to an inch, the root-fibres from the Chestnut doubtless having rapidly encroached upon the richer food supplies in the Narcissus ground, and to an extent not anticipated when planting the bulbs. All this, of course, very natural, and if not, indeed, an instance of the survival of the fittest is at least an example of the survival of the strongest. But, having found so much, the question arises as to how we may in years to come assist this useful late Narcissus to its flowering, particularly when unfavourable weather prevails. Rich and good food can readily be given, yet we cannot compensate for cold, and, above all, harsh drying winds with frosty nights, should such prevail at the moment the flower-scape is apparent, say when a foot or more high. This is, I think, the most critical stage for these things, and doubtless the warm, moist weather this spring in conjunction with other things has favoured their flowering in no small degree. Nor should the fact be overlooked that generally in the north the blindness so-called is less than in southern counties, and the question arises whether, by being somewhat later in appearing, and therefore showing for flower, more congenial weather is experienced, which in turn is helpful to the plants. In any case, much of this may another year be determined by allowing the bulbs now flowering to remain, or some of them, and by giving the usual mulch again in the autumn ensuing. In this way neither the quality nor quantity of the food supplies would be lacking, and the flowering in 1899 would in a considerable degree depend on climatic or atmospheric congeniality. We can so ill afford to be without this valuable Narcissus that it is worth every endeavour to secure a good supply of bloom annually. Whatever the causes leading up to its flowering so well and so abundantly this spring in gardens differing widely in soils and surroundings as well as cultural details, we are at least grateful for a full crop of the large, beautiful and pure, as well as fragrant blossoms.—E. JENKINS, *Hampton Hill*.

— Of this one can now write with confidence, as the flowering season is over and it has been a thoroughly good one. I have been for years, and with varying results, experimenting with this plant, and, having a large number of bulbs to deal with, I have tried all the methods of treatment which I have seen advised. The most successful results have been given by bulbs which were planted last year 6 inches deep and with a heavy dressing of decayed manure buried 6 inches below the bulbs. With these there have been no blanks and the flowers have been very full and fine. In planting, the top soil was removed and the manure dug into the bottom spit; the beds were next trodden over and the bulbs distributed equally over the surface, after which the top soil was used for covering them. By planting in this way there is no fear of the bulbs being "hung up," as happens frequently when planting with a dibber. On a border of better soil holes were dug and manured, the bulbs in this case being buried 9 inches deep; the result here as to flowers was almost the same as in the preceding experiment, but the leaves appeared somewhat strangled and unhappy, and I shall not again plant so deeply. Another lot planted in the ordinary way, 4 inches deep in fair soil, without

manure, threw up many flower-stems, but did not succeed in opening a single flower. In each case bulbs were selected as nearly as possible alike in size. On each bed and group half the spikes had the points of the flower-sheaths nipped off before any of the embryo flowers began to wither, but this made not the slightest difference to the flowers and will be with me included with other fallacies disproved, among which also may be placed the notion that the bulbs dislike removal. The results attained confirm the opinion based on former experiments, that the roots in light sandy soils require manure in quantity, within reach, but not applied close to the base of the bulbs, and that lifting and replanting, if done while the bulbs are dormant, so far from doing any injury, are really a great help, provided the soil given is in good heart. Starvation is too often the lot of many home-grown bulbs in private gardens.—J. C. TALLACK, *Licemere Park, Bury St. Edmunds.*

FLOWER GARDEN NOTES.

PHLOX SUBULATA.—I do not remember a finer display of *Phlox subulata* and its varieties than has been furnished this season, and a noticeable point is, that in addition to the splendid mass of colour, the display was very long-sustained, attributable no doubt to the dull weather and copious showers. That these alpine *Phloxes* are particularly adapted for carpeting dry poor borders is evident from the annual mass of flower to be seen in the little Queen Anne's garden at Hampton Court, where the soil is naturally dry and light, and anything in the way of stimulant, either in the ground or on the surface, is conspicuous by its absence. Their adaptability as a carpet for large beds already partially planted with the tall summer and autumn flowering *Phloxes* has already been advocated in "Flower Garden Notes." I should like to add that where used for this purpose it is not advisable to plant too thickly; leave sufficient room so that a small hoe can be worked between the plants. Such beds once planted may remain undisturbed for, say, three years, and if the alpine *Phloxes* are set too thickly it will necessitate hand weeding instead of hoeing, a small matter perhaps, but one worth consideration in all places that have to be worked with a small staff. The introduction of new varieties has given us several different shades of colour. They go now from the white form through various mauves and pinks to the purple of *atro-purpurea*, and may be selected accordingly to contrast with the taller plants. They may be propagated now that the flowering season is over, and will make nice little stuff for autumn planting. For place and compost suitable for these, also later for Pinks, Tufted Pansies, *Antirrhinum*s, *Pentstemon*s, and similar things, a two or three light frame, or an extemporised frame that can if necessary be covered, should be chosen, and the contents of all boxes used for annuals and bedding plants emptied into it. Add a fair proportion of fresh leaf-soil and ordinary red sand, give a good treading, insert the cuttings firmly, and shade for a time from hot sun. In noting above that beds of *Phloxes* once formed may remain undisturbed for three years, I am aware that such treatment may not be conducive to the production of exhibition spikes; but if the plants are well done at the outset—that is, if the soil is naturally light and dry, they get a bit of heavier compost, in the shape of two parts loam and one of cow manure, worked round them at planting time—get a good mulching each year, and have the shoots thinned out to seven or eight of the strongest, a very fine mass of colour and very fair individual spikes will be the result.

CARNATIONS.—Considerable losses are to be seen on Carnation borders, especially in the case of some varieties, and the dark-coloured wire-worm is evidently responsible for the same; at least, in all cases where investigation is made

round the miffy plants one or more of these insects is to be found. The growth, too, is somewhat thin and weakly, but this, perhaps, is hardly to be wondered at considering the weather we have experienced through May and June. There is, however, the promise of a good display of bloom, three and four stout flower-stems being in evidence on many of the plants. Staking will soon be necessary, and should be performed so that the flowers are seen to the best advantage, avoiding undue formality, but at the same time securing individual stems, so that they are not broken down by heavy rain or wind, flowers splashed with dirt being practically worthless. Although in the majority of cases a large number of new named sorts cannot be annually grown, it is a good plan to have just a few on trial, together with a small batch of seedlings, with the view of weeding out any sorts that either from calyx-bursting, tender constitution, or long-delayed rooting from the layer are not altogether desirable. It is not advisable to dispense with named sorts in favour of seedlings until the latter have a second trial, in order to ascertain if the favourable opinion formed of them can be thoroughly verified.

HARDY PERENNIALS FROM SEED.—Now that planting is at an end, attention may be directed during the present month to the sowing of any hardy perennials not on hand that are likely to be in request for another season. Such sowing may be recommended from a double standpoint. In the first place, seedlings of good things thus acquired may take the place in prominent borders of more common plants; and in the second, because a batch planted in some outlying part of the garden is always acceptable for cutting. A portion of a narrow slip garden, especially if the soil here is naturally deep and moist, will be found useful for the purpose, and the species and varieties of the same can be planted here in beds of 4 feet, 5 feet, or 6 feet, as may be deemed advisable, with intervening alleys of 2 feet to admit of cutting the flowers without too much treading on the beds. To the lover of hardy plants, propagation of this kind is peculiarly interesting, and the seedlings are watched with keen interest right away from their first appearance above ground until the flower is clearly defined. I prefer boxes to the open ground for sowing, the double advantage being that while yet in a young stage there is better opportunity of warding off the attacks of insects, and, in the case of seed-sowing, the chance to particularise in the covering given to different seeds. The seeds are sometimes very tiny and naturally only require the least bit of soil on the top. The strips of wood at the bottom of the boxes should be fairly close together, not more than a quarter of an inch apart. A few small crocks may first be placed, followed by an inch of rough leaf-soil, the remainder of the compost consisting mainly of old potting soil, not too dry, to which have been added a bit of fresh leaf-mould and a little sand; the surface should be even throughout and pressed fairly firm. Prepare the boxes as it might be to-day, give a soaking of water, and sow to-morrow, taking care the seed is evenly covered, and, as hinted above, to discriminate as to the depth of covering according to the size of seed. Place the boxes in a frame facing north, and shade in bright weather. Be careful the squares of glass are intact, as water running in on the boxes will wash out the smaller seeds, and, as germination takes place at various periods, the boxes must be carefully watched. It is not necessary to occupy space with a list of things, because the majority of herbaceous plants can be raised in this way, and the list would naturally be a long one. It may, however, be pointed out that, with the demand for cut flowers ever on the increase, preference should be given to those things that can be utilised for this purpose as well as to make a display in the garden. The selection should also be comprehensive so far as the different seasons are concerned, and may include the many species and varieties available between the first blooms

of the *Doronicums* and the waning flowers on the panicles of the *Sea Lavenders*. I noted above that a planting to furnish cut bloom might find a place in a slip garden. If there are trees it may not be advisable to plant close up to them, but many of the things that can be selected will be benefited by partial shade. Among the things sown this year whose progress will be watched with special interest are extra good strains of *Aquilegia*, *Pentstemon*, and *Lupinus polyphyllus*, two new *Geums*, *Sidalcea Listeri* and *Hedysarum multijugum*. It is hardly necessary to add that not the least interesting point in this propagation of hardy flowers is that it is within the reach of all flower-lovers who can command a small cold frame to receive the seed-boxes and one of somewhat larger size for pricking out the seedlings until they can be consigned to permanent quarters. E. BURRELL.

Claremont.

Gaultheria trichophylla.—I sent you a note a short time since on the free flowering of *Gaultheria trichophylla*. There is now a fine crop of the beautiful blue berries, each half an inch long and three-eighths of an inch in diameter. They are so hidden by the foliage that I hope a good many will escape the birds. (*Genista dalmatica* is flowering freely for the first time in my rock garden.—E. C. BUXTON, *Bettws-y-Coed.*

Sweet Peas.—I question if there is much gain in sowing these beautiful annuals in small pots with a view to forwarding the flowers, for it is not easy to get them into blossom before the garden is gay with other things, and the transplanted rows have never quite the vigour of those left quite undisturbed. If a way could be found of prolonging their season without at the same time injuring the individual plants operated on it would be a great help, but to do this a certain amount of warmth would be necessary in the earlier stages, and this is fatal to vigour or continued health and a free-flowering condition. I sowed about a dozen of the newer varieties in pots in a cool house this season and kept them quite cool until they were planted out, but though they are as strong, or nearly so, as rows sown in the open, one will be in flower almost as soon as the other. The improvement in varieties is very great, even the common or mixed seed producing very fine and highly-coloured flowers, while their value as cut flowers needs no word from me. But often they are spoilt by arranging them with heavy foliage of some kind, when they would look much nicer without any. A few of their own tendrils and stems are prettiest, while a spray or two of *Gypsophila* has also a pretty effect.—H.

A roof garden.—As I introduced the subject of roof gardens to the readers of *THE GARDEN* last year, I was much interested and pleased to see what should eventually be a charming place of the kind in Trinity College Gardens, Dublin. A portion of the yard was to be roofed over with iron, and Mr. Burbidge conceived the happy idea of adding to this a good coating of concrete and converting it into an Iris roof garden. There are about 2 inches or 3 inches of concrete and this is surfaced over with from 3 inches to 4 inches of road scrapings, in which the Irises were planted last October. It was not the most suitable time for Iris planting, but in gardening one has to do many things not according to rule, and although the Irises are as yet dwarfed in growth, they do not seem to have suffered. They comprise some of the best forms of what are popularly called the German Irises. These Irises do not appear to be flowering so freely as usual this season, but those on the roof garden referred to are in this respect more satisfactory than those on the borders in the College gardens. Seeds of *Aubrietias* and other plants have been sown among the Irises, and it is to be expected that some pretty undergrowth will be produced from these seeds. In the meantime grass has sprung up freely among the plants of Iris and looks quite in keeping with the flowers. It is doubtful, indeed, if there is anything better than grass as a groundwork for the bold leaves and stems of the Flag Irises.—S. ARNOTT.

PYRETHRUMS.

THE wet spring and early summer have suited these moisture-loving plants, and they have for the past fortnight been extremely beautiful. I do not grow the named varieties, but seedlings, and some very fine plants may be raised in this way when the strain is good. Few flowers are more beautiful in the garden or cut on long stems and simply arranged with a little of their own foliage. Their culture is very simple, seedlings raised in January flowering the first season and making fine clumps by the second. Where the soil is very heavy, a little road-grit and leaf-soil, or anything of a lightening nature that happens to be at hand, may be dug in. If the clumps become too large, or if there is a good variety which it is necessary to propagate, the clump should be taken up in early spring when the growth is starting and carefully divided with the knife. Every crown will make a new plant, of course, but it is not often advisable to cut them up so small as this. As showing how easily they are grown, I had occasion to lift some old clumps after the flower-buds were visible, and though late for dividing, they were

and foliage are cut in sufficient length they are most ornamental. Some seven or eight years ago I called on Mr. Ingolden, who was then at Marston, and there I first saw them used in this way. Since that time I have used them largely. I grow them in self-colours principally, as these are far more effective. Recently I noticed some vases and big bowls in our drawing-room. These had a fringe of greenery round the out-side of the bowl. The Pansies were cut with long stems and arranged lightly, one colour in each receptacle. Although there was a goodly number of cut flowers of many kinds, both from stoves and the open garden, there was nothing to equal the Tufted Pansies. In low glasses arranged with a little light greenery, one colour in each, I find them most useful for placing on the dinner-table. Another recommendation is their enduring nature. I have had them stand in a vase from ten to twelve days by giving them fresh water occasionally. They will stand a week and look well in a warm room. When one comes to look at the length of time these continue in bloom, and that they can be grown in any good soil, one

Vitis heterophylla variegata. Engraved for THE GARDEN from a photograph sent by Mr. J. N. Gerrard, Elizabeth, New Jersey.

too large for planting, and each one was split into three or four, according to size. They were carefully planted and watered and they never looked back, being now in full flower and as fine as any in the garden. The dripping season has been all in their favour, of course, but I am inclined to think a good deal of root-action takes place in spring, which helps the plants to re-establish themselves, otherwise they could hardly look so well. In the colours there is considerable variation, but all are pretty and worth growing. The single kinds are first favourites with me, and some of the semi-doubles with long petals and a pretty quilled centre are as fine as a Japanese Anemone-flowered Chrysanthemum. H.

Tufted Pansies as cut flowers.—Those who have not used these for cutting have lost sight of one of their best features. When cut they are not often used in private gardens. They have comparatively no value when the blooms are picked off singly, as all the natural beauty of the flower is lost. But when the shoots with flower

wonders they are not more extensively grown. Last season I raised seed in a box and pricked the seedlings out, and now I have some most useful colours to cut from out of these seedlings. It does not injure them to cut the shoots, as others soon follow to keep up the supply.—DORSET.

Brompton Stocks.—In a recent issue "W.S." was speaking of the behaviour of these in his garden, and how disappointed he was in having so many singles. I can assure him he is not alone in this way. An evening or two ago I saw a big patch in a cottager's allotment of the white kind, and out of several score there was not a double amongst them. I asked him where he obtained his seed from, and he told me from a lady who lived in a cottage and had a liking for these. At the time he saw them in bloom there was a goodly number of doubles amongst them. I am under the impression the time when they are in bloom and the state of the weather have much to do with the future crop of seed, as the pollen from the doubles may not get to the singles.—D.

TREES AND SHRUBS.

VITIS HETEROPHYLLA AND ITS VARIETIES.

THE typical *Vitis heterophylla* is not very much grown in gardens, certainly not so much as either of the two varieties here mentioned. It is a free-growing Vine of medium size with leaves of a lustrous deep green, suffused, especially when young, with a reddish tinge, which is still more pronounced on the veins, midrib and leaf-stalks. The leaves are usually deeply three-lobed, but sometimes almost entire. It is a common plant in Japan, where it was noticed and described by Thunberg over 100 years ago. The fruits are small and blue.

V. h. VARIEGATA—of which an engraving is here given—is one of the prettiest of all Vines with coloured foliage. Unfortunately, it is neither so strong-growing nor so hardy as the green-leaved type. When grown in the open air it should have a sheltered, but not unduly shaded position. It is only in such a situation and in warm seasons that it is seen in any great beauty out-of-doors. It is frequently grown in pots for greenhouse decoration during the spring and summer months, and its foliage is at that time very beautifully coloured. The green ground of the leaf is mottled and blotched with delicate pink or almost pure white, the young shoots, too, being of a pretty pinkish purple. It appears to have been introduced from Japan about sixty years since, for it is recorded as being in cultivation in Rollisson's nursery at Tooting in the early "forties."

On the whole, the most attractive form of *Vitis heterophylla* is the variety

V. h. HUMULIFOLIA.—It was first discovered in North China by Dr. Bunge about thirty years ago; since then it has been found in Japan. The leaves are not so large as those of the ordinary *V. heterophylla* and the deep flop-leaf-like lobing is more constant. But its chief beauty is in its fruits. These are about the size of small Peas and of a lovely shade of turquoise-blue. The plant requires a place specially made or selected for it. An undue luxuriance of growth has to be guarded against, as this is prejudicial to the formation of fruit. The late Mr. Ingram used to grow it at Belvoir in pots in a greenhouse for the sake of the fruits. This is not necessary, near London at all events, but a place on a south wall should be given it for the proper ripening of the wood. There is a plant at Syon House which, I believe, fruits freely almost every year. I remember seeing it very beautiful there about four years ago, and it was planted against a wall in a narrow border close to a hard and well-used path. When merely trained up a stake in the open ground it bears a little fruit, but never with that freedom which makes it at its best the most beautiful of the ornamental fruiting Vines. W. J. B.

BUDDLEIAS.

CONSIDERING its size (for it comprises about seventy species) the genus *Buddleia* is of but little importance in gardens. A great many of the species are tropical and sub-tropical and of a nature that makes them become weedy and gaunt in habit when cultivated under glass. One species from Madagascar (*B. madagascariensis*) is occasionally grown in warm greenhouses for the sake of its long spikes of bright orange-yellow flowers. There are, however, some half-a-dozen species besides that can be grown out-of-doors in the southern parts of the kingdom, and which, although not in the first rank among hardy shrubs, are well worth growing. This applies especially to *B. globosa*, which is quite distinct from all other hardy shrubs; and some of the others have their value

enhanced by flowering at a season when the bulk of hardy shrubs is past. The generic name was given by Linnæus to commemorate the Rev. Adam Buddle, who was at one time vicar of Farnbridge, in Essex, and died in 1715, and of whom it was written more than 100 years ago that he was "an ingenious English botanist whose dried collection in the British Museum is still resorted to in doubtful cases." Mr. W. B. Hemsley observes of the genus *Buddleia* that it is one of the most sharply defined in the vegetable kingdom, and that it is, indeed, so distinct that it is not easy to determine its closest relationship to other genera. None of the species here mentioned is strictly woody, the growths retaining a semi-herbaceous character for a year or two. *Buddleias* do not want a soil of more than moderate richness and prefer the sunniest positions available. Some can only be satisfactorily grown against a wall. All of them can be increased by means of cuttings.

B. COLVILLEI.—One of the most interesting plants (and there are many such) in Mr. Gumbleton's garden at Belgrove, near Queenstown, is a large plant of this Himalayan *Buddleia*. Mr. Gumbleton enjoys, I believe, the distinction of being the first to flower it in Europe. It has since flowered with Mr. Chambers, of Haslemere, and perhaps elsewhere. Unfortunately, it is not quite hardy near London, although against a sheltered wall it survives such winters as the two last ones, but it has never yet got strong enough to flower. Indoors, on the other hand, it grows too soft and succulent and the shoots do not ripen sufficiently to flower. Mr. Gumbleton has his plant growing against a garden wall, of which it covers, if I recollect aright, a space some 10 feet or 12 feet in length. Of the *Buddleias* that can be grown in the open air in the British Isles this is by far the most beautiful. Sir J. Hooker has even said that it is the handsomest of Himalayan shrubs, and that it is impossible to exaggerate its beauty as seen on the borders of the Sikkim forests covered with pendulous masses of rose-purple or crimson flowers. There it is found at altitudes of 9-12,000 feet, and is a large shrub or even a small tree as much as 30 feet high. Its leaves are 5 inches to 7 inches long, lanceolate, the margins set with shallow teeth, dark green on the upper surface, paler below. The younger parts of the plant are covered with a greyish pubescence. At Belgrove the flowers appear during June; in the Himalaya during July and August. They are produced in pendulous, terminal panicles 12 inches to 18 inches long, are of a rosy purple or crimson and much larger than those of any other *Buddleia*. Each flower is about 1 inch long, the lower part tubular, but with four spreading lobes at the mouth, where it measures three-quarters of an inch across. There is a coloured plate of this *Buddleia* in THE GARDEN for June 10, 1893.

B. GLOBOSA.—In the neighbourhood of London and the home counties this species has proved to be the handsomest and most useful of the *Buddleias*. It is hardy, except during the very hardest winters, when it may be cut back severely, but I have never seen it killed outright. In ordinary winters it scarcely suffers at all. It grows to be 8 feet, 10 feet, or even 12 feet high, and from all the other species here mentioned is quite distinct, because of its flowers being closely packed in globular heads, each of which is about 1 inch across and borne with several others on a raceme at the end of each branch. These balls of flowers are bright yellow and appear in June. The leaves have short stalks, but are themselves long, narrow, and taper to a fine point; the margins are minutely and regularly crenate, and the undersurface, as well as the young growths, are covered with a pale brown wool. The upper side is a dark green, and much wrinkled. The plant is now an old one in English gardens, having been introduced by Messrs. Lee and Kennedy in 1774. It is a native of Chili, and the only hardy species that comes from the New

World. It has been exceptionally fine this year, but is now nearly past.

B. JAPONICA.—Whilst this is not the handsomest, it is the hardiest of the *Buddleias*. It is a spreading bush, and does not appear likely to grow more than 5 feet high. The stems when young are markedly 4-angled, or even winged, and the short-stalked leaves are each 3 inches to 6 inches long and lanceolate. The flowering season extends from mid-July to September, the blossoms being crowded on a terminal, sometimes branching, panicle 6 inches to 8 inches long. Each flower is about $\frac{1}{2}$ inch in length, tubular, with four small slightly-spreading lobes at the apex. The colour is a pale lilac. Seeds are ripened in remarkable abundance, the shoots being weighed down in autumn by the heavy racemes of closely-packed, conical seed-vessels. These, or a large proportion of them, should be removed, as they tend to shorten the life of the plant. But it must in any case be renewed every few years by means of either seeds or cuttings. Some confusion has been caused by the continental growers calling this plant *B. curvifolia*—a name that belongs to a species probably not in cultivation, and a native of the East Indies.

B. J. VAR. INSIGNIS is a dwarfier, more compact, and erect-growing plant, raised from seed in France over twenty years ago. It suggests a *Veronica* in its mode of growth and inflorescence, having erect, dense racemes of rosy lilac flowers. It blossoms at the same time as the type, but is a great improvement on the ordinary *B. japonica*.

B. LINDLEYANA was originally discovered by Robert Fortune in Chusan, and he sent the first seeds of it to the Horticultural Society in 1843. Fortune was so struck with its beauty that he named it after Dr. Lindley, who was then the leading figure in horticulture. Under cultivation in this country it has not proved a great acquisition. It is not very hardy and requires a wall to grow it satisfactorily; in the open it is killed nearly or quite to the ground every winter, and I have never seen it bloom with freedom away from a wall. It bears its flowers on slender terminal spikes, each 6 inches to 8 inches long, and they are of a reddish purple colour. In the typical plant the leaves are ovate, with a long tapering point, and almost or quite entire, but there is a variety with lobed leaves. Except for gardens in the extreme south and west, or for those who can give it room on a wall, this *Buddleia* is of little value.

B. INTERMEDIA.—In 1871 Mons. Carrière, of Paris, noticed among a batch of seedlings of *B. japonica* three plants, which, when grown on, proved to be distinct and intermediate between that species and *B. Lindleyana*. The conclusion was, therefore, come to that they were hybrids between the two species, effected probably by some insect; hence the present name was given to them. This hybrid very much resembles *B. japonica*, although the leaves show the influence of *B. Lindleyana* in their shape and greater smoothness. Nor are the seed-vessels so large and heavy as in *B. japonica*. The flowers are of a greyish lilac outside and of a more violet shade within. The plant is handsome when in flower, and certainly not inferior to *B. japonica*; it blooms at the same season as that species.

B. PANICULATA (syn., *B. crispata*).—This species was originally discovered by Dr. Wallich in Kumaon, but its first introduction to the British Isles was due to Major Madden, who sent seeds gathered near Almorah, in the Western Himalayas, to Glasnevin. It has a wide distribution in North India, extending, in fact, from Afghanistan to Burmah. Growing at high altitudes, it has proved quite hardy here. A plant raised from seed sent from Afghanistan by Dr. Aitchison in 1879 is still at Kew—a rounded bush over 5 feet high. It is a very distinct plant and could scarcely be confounded with any other of these *Buddleias*. The leaves (especially beneath) and the young stems are covered with a whitish woolly substance, which gives the plant quite a character of its own. The flowers appear in dense whorls on an erect spike and are of a bright lilac colour. It

starts into growth early and is frequently injured by late frosts. It is said to flower in the Himalayas from February to May and to scent the atmosphere around with its fragrance. Here it is the earliest of the *Buddleias* to flower, and was this year blossoming in May, but it never makes a striking display.

B. VARIABILIS.—Among the specimens of new Chinese plants sent to Kew by Dr. Henry in recent years was a *Buddleia* to which Mr. W. B. Hemsley gave this name. In 1893 seeds of it were sent to M. Maurice de Vilmorin and to the Paris Museum by the Abbé Soulié. It is now spreading in cultivation, having proved to be quite a handsome species as *Buddleias* go. It is a vigorous grower, sending out shoots in one season 4 feet to 5 feet long (as much as 8 feet in France). The leaves are 6 inches long (sometimes considerably more), sharply toothed, the upper surface smooth or nearly so, the lower one covered with a close, dull white or pale brown, felt like substance. The flowers appear in small clusters thickly set on panicles sometimes 1 foot long, that are borne at the end of the main branches and on the secondary branches that spring from the axils of the uppermost leaves. The colour appears to vary. Dr. Henry describes the flowers on wild plants as "rose, orange-coloured inside"; at Kew they have been rosy purple, and M. de Vilmorin mentions a plant with violet-coloured flowers. Probably the differences in foliage to which Mr. Hemsley's name refers are also equally present in the flowers. In habit it certainly varies. At Kew one of the plants has weakly, almost prostrate branches; whereas another is sturdy and upright. It appears to be of about the same degree of hardiness as *B. japonica*, the points of the shoots dying back in winter. It has been found in several districts in Central China, also in Eastern Thibet. It flowers during July and August. W. J. BEAN.

GARDEN FLORA.

PLATE 1177.

THE ALPINE FOREST HEATH.

(ERICA CARNEA.)

(WITH A COLOURED PLATE.*)

As we have said more than once in THE GARDEN, this we believe to be the most useful little mountain shrub ever introduced, owing to its earliness and hardiness; which enable it every winter to be full of promise in thousands of buds, and ready to open into bright flower in the dawn of spring. Thus, last winter, owing to the mild season, it was not only in flower, but in bright, hearty flower, in January, lasting three months in that state; and though we cannot always count upon such a season, it is scarcely less useful in any season, however severe, emerging out of the snow laden with myriads of flower buds. It is also typical of the many plants in our gardens that are not made effective use of. It is not so much novelty we want as artistic and effective use of the things we know to be good and effective. Now, in many places this Heath may not be used at all in any right way, or we may here and there see a small patch on the rock-work or a worn-out small bed. Any one who treats this plant so has no idea of its value. It is not dear, and it is also very easily increased in any soil by pulling it to pieces almost at any time throughout the

* Drawn for THE GARDEN at Gravetye Manor, Sussex, by H. G. Moon. Lithographed and printed by J. L. Goffart.

winter, or spring, or autumn. Among the best uses for it is forming an undergrowth to beds or groups of choice shrubs of Azalea, Rhododendron, Andromeda, or any like shrubs, in which way we not only get its full beauty, but, perhaps, double the blooming season of our groups or beds; also the Heath flowers with their fine rosy colour are finer in effect if we see them "broken" by other things above and about them.

There are varieties of this plant, and it is well to have a good, fine rosy variety which is not difficult to get. Lately there has been a hybrid between it and the Mediterranean Heath, which without having quite the brightness of our plant, has an almost equally pretty bloom, which in our garden lasted five months during the past winter and spring, that is to say, was in flower in December and lasted until May. At one time we used to argue that the right use of hardy flowers gave us eight months of bloom instead of the three months of the bedding plants, but with the aid of this and other winter-blooming Heaths and the early Lenten Roses, and winter and early spring flowers, eleven months is nearer the fact. At least this is true in the southern country. True, one year in seven, perhaps, we have a very hard winter and things may be delayed for a month or six weeks, but the usual result of this severity is greater beauty of the early bloom. It would be better for all our hardy things if an annual rest of six weeks or so under the snow were the rule.

THE WEEK'S WORK.

KITCHEN GARDEN.

ROUTINE WORK.—With an agreeable change in the weather the cultivator will now have an opportunity of using the hoe freely among growing crops. Weeds hitherto have been difficult to keep down, and every bit of soil will now pay for having the surface frequently loosened. With a change from cold, sunless days to heat and drought means must be taken to prevent shallow-rooting crops from flagging. Peas in light soil just in flower or podding will be benefited by mulching with short manure. I find cow manure excellent in a light soil. The same remarks are applicable to French Beans, as unless the roots receive plenty of moisture the plants become infested with red spider and fail to crop. French Beans are usually planted close; in their case it is a good plan to mulch the whole surface with strawy litter. This is of great value in retaining moisture, and if the plants are given one thorough watering weekly the mulch will conserve the moisture. During July and August I have found it a good plan to water the French Beans overhead rather late in the day, as with the foliage damp during the night red spider cannot make much progress. Runner Beans as they reach the upper portion of the stakes may be topped, as this assists the plants to set the early flowers at the base, and unless the pods are needed at a later period there is no gain in allowing runners to go away to top, as the crop is more difficult to gather and the plants often suffer from want of moisture. I top at 5 feet to 6 feet, and by so doing get a heavy crop, which may be gathered with ease. In gardens near towns this mode of culture is a great saving of stakes. Runner Beans sown late and not staked should have a few short stakes or be pinched at

15 inches from the soil, frequently topping the later growths. The early plants of Brussels Sprouts will now benefit by being moulded up. Cabbage quarters should be cleared as soon as cut over and a different crop planted. I find Celery follows the early Cabbage well, and the soil thrown out of the trenches will be useful for a quick crop, such as Lettuce, when the ridges are finished. There is a great saving of time in making the Celery trenches some little time before planting. Late-sown Celery should be kept well watered; a thorough moistening overhead late in the day will make a sturdy, clean plant.

TOMATOES IN THE OPEN.—Many can grow a few plants of Tomatoes against a south wall. The plants will now be setting freely if grown specially for early fruiting, as, though the progress made earlier in the summer was slow, I note the fruits have set well. With plants at the stage named I would advise feeding. Many give manure at planting, but it is not well to do so, as growth is too robust. I mulch with spent Mushroom manure. This is light and retains moisture, and if other food is needed, nothing is better than liquid from stables. In training avoid crowding. So far I have never seen any better mode of culture than training in cordon fashion, one or several leads according to the strength of the plants. Foliage may be reduced, but I am not in favour of crippling the plants, as it stands to reason plants divested of all their leaves cannot make progress. Close stopping of side shoots will be necessary, and plants in the open trained to stakes will need attention. Here one main growth is ample, as the season is short in which the fruits have to set and ripen. A little closer stopping of foliage with strong growers is admissible. The growths should be kept close to the stakes to allow the fruits to get light and sun.

VEGETABLE MARROWS.—The plants are now growing after a long spell of cold weather, and there is often a tendency to gross growth and fruits are few in such seasons if the plants are growing in rich soil. I would advise closer attention to stopping, not allowing the plants to become crowded. Much better results are secured from plants not given much manure at the start, as a sturdier growth will give a greater quantity of fruits. Marrows will now pay for feeding, and if in rows it is a good plan to mulch between these with short litter, liberal supplies of liquid manure also greatly benefiting the plants. In many gardens the fruits are left much too long on the plants. They are much best cut in a small state before seeds form, as then others set. In dry soils after a hot day I have found watering overhead late in the day of great benefit. A late lot of plants sown specially for the purpose will be useful. I plant these rather close, stop hard, and at the approach of frost in the early autumn give a night covering, and by so doing get much later supplies.

SAVOYS.—The Savoy crop is more useful in mid-winter than in the autumn, as at this latter date there is a wealth of green vegetables. I advised sowing later than usual to get the crop at the latest period possible. Early Savoys as regards quality are not equal to good Coleworts; so those who have plenty of the latter may with advantage make the Savoy a succession crop. Now is a good time to plant Savoys in quantity for early heads from October to Christmas. The Early Dwarf Elm, Dwarf Green Curled, and Tom Thumb are all good and make a rapid growth. They may be planted in rows 15 inches apart and only half that distance in the row. For late use the well-known Drumhead is still one of the best, but it needs double the space advised for the small earlier kinds. Last year I grew an intermediate variety and found it much liked. This was Sutton's Perfection, a very compact grower. New Year, a new variety, is a very large Savoy and may be had quite sound well into March. This variety does not split in bad weather like the older Drumhead. If a late small Savoy is wished for, Bijou is an excellent variety and very late. In planting it will be found advisable to draw drills in light soils, as this lightens the

labour when water is needed in the early stages of growth. Savoys for late use do well planted on north or east borders. S. M.

FRUITS UNDER GLASS.

PEACHES AND NECTARINES UNDER GLASS.—Those trees from which the crop has now been gathered should receive every attention just as much as if such were not the case. There ought not to be any relaxation of effort to keep the trees in the best possible condition. Immediately the crop is gathered, a thorough watering will in most cases be needed, as in all probability it will not have been done, nor should it be, in extensive borders just at the finishing period. In conjunction with the watering, also note the condition of the trees as regards their vigour of growth or otherwise. If disposed to grow too strongly, do not now manure them so as to excite the growth still more. If in good condition, with a full or heavy crop taken from them, the growth should not be excessive, in which case an application of a well-proven artificial manure will be of decided advantage. It will restore to the soil that needful food wherewith to build up the trees for another season's fruiting. In my own case I shall apply a moderate dressing of Dickson's manure, which, as already stated, has been proved to be well suited to the soil, being of marked benefit to weakly trees in particular. This will be watered in, after which no more manure of any kind will be applied this season. If the borders for good reasons have been mulched to assist the crops and to prevent excessive evaporation, look well to it that these do not suffer from drought, for under a genial-looking surface the border may be dust-dry even, and if this be the case, the very first stone is laid towards bud-dropping another spring. Give all the ventilation possible now to these houses, never closing them even for the sake of other plants that may be in them if it can possibly be avoided. If insects have been troublesome, lose no time in applying strong measures for their destruction. If it be aphid (either green or black), fumigate with N. L. All, than which there is nothing better or safer. If it be red spider, syringe well with sulphur and water well mixed. With this, syringe the trees and all woodwork, and the glass, too, after which leave the house as it is for a week or so, then if more are still to be seen repeat the application, and after another interval in all probability the spider will not give any more trouble. Scale in some cases is troublesome, and if it be present in only small numbers give just as much attention now, otherwise by the autumn it will have increased amazingly. Either a moderate dose of carbolic soft soap or one of Gishurst Compound brushed in upon the old wood or syringed on the trees should prove efficacious. If not, apply a stronger dose of the same compounds. In dealing with the mealy bug, which one at times comes into contact with around the base of good fruits even upon exhibition tables when critically inspecting the specimens, strong measures should be taken to prevent any increase. If this plant pest can be stopped in its onward career now it will be all the better. All the crevices of the old wood should be carefully looked into for young broods, using a strong solution of a well-proven insecticide mixed in hot water, which may be safely used up to 130° or 140° Fahr., keeping it at these temperatures by means of a spirit lamp such as that now used in evaporating liquids. Half of the insecticides used are rendered ineffective or partially so, be it noted, by being applied in too cool a condition. Syringe the trees if the bug be spread very much upon them, shading afterwards for a day or two, even when the precaution is taken, as it should be upon such tender foliage, of washing off partially, so as to dilute the compound half an hour or so after application. In conclusion, it only remains to be said that any measures now taken against insect pests must be to the good of the trees for another season, for unless the foliage be retained in good condition

until it has accomplished its work, the fruit-buds cannot, as a matter of course, be so thoroughly well developed; hence not so fully prepared for as early, or perhaps an earlier start another year. Healthy foliage this year means, speaking generally, healthy flowers another year with due attention meanwhile. A partial thinning out of the wood where it is at all disposed to be overcrowded had better be attended to now rather than later on. There is no reason why so much of this work should be left until the autumn or winter pruning. If done now to a moderate extent, more light will be admitted to the trees and more air will circulate round the branches; hence the wood will be better ripened. One has, of course, to guard against late growths as much as possible; therefore any severe amount of thinning may, in the case of vigorous trees, have that tendency; such, for instance, as young trees which are oftentimes very active in making secondary growths. Use caution in dealing with all such as these. Trees that have fully covered their allotted space can be operated upon with safety. These and others which are making lateral growths or breastwood had better be gone over frequently, nipping the shoots whilst still young and tender. For this purpose the finger and thumb may oftentimes be used with more dispatch and to better purpose than the knife. No such wood as this, which one knows must eventually be removed, should be countenanced, and if its removal be persisted in for a few weeks the tree will go to rest all the sooner. Look after any ties also that may, by the swelling of the wood, have become tightened, otherwise these will, if of string or yarn, cut the bark and cause an over-growth or injury from pressure against the wire. Where injury has been done by galvanised wire in past seasons, it should be instructive to watch as to when such injury really occurs.

FRUITING TREES.—Houses in which the trees are now fruiting should be kept moderately cool in any case; even then, relatively speaking, the temperature will average that of the earlier houses. A free circulation of air will add to both flavour and colour, whilst at the same time it will not encourage insect pests so much, unless it be the red spider, for which the syringe at this juncture, with clean water only, is a good remedy. Fire heat is scarcely needed now in any case. Even if a house has to be hastened on, it is better to keep it a little closer than to depend on artificial warmth, which I have often noted is not so beneficial. Where the fruit is ripe ventilate freely, and continue to shade if need be so as to retard the fruit, removing all such shading immediately the fruit is picked. As in houses where the crop is all taken off, so here look to the due thinning of the wood so as not to shade the fruit and thus prevent it from attaining its full colour. As soon as Peaches show signs of colouring cease to syringe the trees. Nectarines, on the other hand, by reason of their smooth skin, do not retain the moisture; hence these may, if occasion requires it, be syringed a few times later than in the case of Peaches. See, however, that they are quite dry by nightfall. Watering will need regular and close attention whether the borders be inside or out, or partly both. In the latter case take care that the inside roots do not become drier than those outside, or the latter will assuredly make most headway. Give water freely when its need is apparent, and guard against too frequent applications by mulchings upon shallow borders. Continue to feed these trees artificially that are bearing heavy crops of fruit. For present use a quick-acting manure is the better one to use, such as one in which granulated blood is used as a component part. There is time of course in the case of the latest crops to assist in the perfecting of the stones, in which case use manure in which bone-meal or its equivalent prevails to a

large extent. If the latest trees are seen to be carrying too heavy crops through the stoning process, relieve them of the smallest fruits or those badly placed. So long as there is a fair margin over the usual crop carried by any tree there need not be much fear. In houses newly planted the growth is as a matter of course the primary consideration. In the first place see that the aphides do not injure the points of the young shoots and thus partially arrest the growth or divert it into other channels. I am no believer in the old-fashioned idea of not encouraging lateral wood on young trees. Get all the trellis covered, and that as quickly as possible, is the advice now given. So long as the lateral shoots are not at the back of the trellis or foreright ones, lay them in and regulate their growth so as to well balance the tree all over by pinching the leading shoots as occasion may require. If more of this encouragement were given we should hear far less of canker and its attendant evils. If the borders be well made at the outset with good material there will not be any occasion to feed these young trees.

flowers set in long calyces that showed no sign of bursting. Altogether I think it the most promising yellow variety I have ever seen, and predict for it a great future among those who are content with Carnations less in size than the *Mulmaison*.—J. C. T.

STOVE AND GREENHOUSE.

POSOQUERIA LONGIFLORA.

THE accompanying illustration represents a fine old evergreen stove shrub, *Posoqueria longiflora*, now seldom seen. This, I think, is to be regretted, for when in bloom it is a handsome plant with its fine trusses of long white tubular flowers, the perfume of which fills the house in which it is grown. Some of the trusses bear as many as thirty individual flowers. Last year the plant figured, produced

Posoqueria longiflora. From a photograph sent by Mr. J. C. Easter, Nostell Priory, Wakefield, Yorks.

It would, on the other hand, be a mistake to do so. Nor should the borders, where made-up ones, be added to too quickly, but rather let the soil they have at present be well filled with roots than add fresh for them to run off into at the earliest opportunity. Guard specially against tight ties or shreds, as the ease may be, in all young trees. It is better to use raffia for all such than string, and brown paper shreds would be better than either cloth or leather ones. HORTUS.

Carnation Primrose Queen.—This excellent Carnation, as seen at the Temple show, appears to have a better constitution than that of most yellow varieties. The plants shown were big and healthy, with plenty of wiry-looking grass, that promised well for the propagation, and a good crop of medium sized, shapely, soft yellow

sixty-two fine trusses. Unfortunately, when any of these are cut they last but a short time, but the individual flowers I have had in water quite fresh for ten days. This is the best way of utilising these charmingly sweet-scented flowers. J. EASTER.

Nostell Priory Gardens.

NOTES AND QUESTIONS.—STOVE.

Carnations diseased.—Can you tell me what the disease is on the Carnation leaves I send you and the best remedy?—J. L.

*** Red spider will cause the leaves to go as in the specimens sent, but it is more frequently caused by bad root action, owing to the plants being grown in unsuitable soil, or soil that has become sour through bad drainage. Red spider can be syringed off, and

the state of the roots should be examined. There is no fungoid disease.—Ed.

Double Begonias.—So far as relates to the large-flowered doubles, it is worthy of note that the densely crowded flowers are getting out of favour, and those having large, broad, flattish or bell-like petals after the form of Camellias and Rhises are most sought for. But it will be a long some ere we shall see on these, stems stout enough to keep the massive flowers erect. How different is it with that intensely scarlet-flowered small double variety Lafayette, the blooms of which are perfectly erect.—A. D.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JUNE 28.

THIS meeting, as far as exhibits were concerned, was one of the best that has been held, the hall being quite filled with flowers of different kinds, those from the open air, including chiefly Paeonies and Delphiniums, being in the majority. Roses, too, were also largely shown. The Malmaison Carnations also added to the interest of the meeting, the groups of these being excellent in every way. Orchids, too, though not so numerous as on recent occasions, made up for this in the quality of the flowers. Fruit and Tomatoes were also well shown.

Orchid Committee.

First-class certificates were awarded to the following:—

STANHOPEA RODIGASIANA.—A distinct and quaint species. In this the petals are pale yellow, each about 5 inches in length, the lower sepals similar in length, nearly 3 inches wide, the interior yellow, thickly spotted on the lower half with large rich brown spots, the upper sepals narrower and not so heavily spotted as the lower sepals. The exterior is yellow, covered from the apex downwards with light brown spots. From Sir T. Lawrence, Burford Lodge, Dorking.

CYPRIPEDIUM L'ANSONI (C. Rothsehildianum × C. Morganiae).—This is a distinct and lovely secondary hybrid, the dorsal sepal pale greenish white, longitudinally lined with rich dark purple; the petals each about 6 inches in length, greenish white, thickly covered with dark brown blotches and spots; the large lower sepals white lined with dark brown, the lip greenish white suffused with purple. A plant carrying a three-flowered raceme came from Messrs. H. Low and Co., in whose nurseries it was raised by Mr. G. P'Anson.

CYPRIPEDIUM MRS. REGINALD YOUNG (C. Lowi × C. Sanderianum).—In this the dorsal sepal is bright yellow suffused with rich purple at the base and having prominent purple lines. The lower sepal is similar in colour, the petals greenish white at the base, suffused with brownish purple at the apex, the basal half thickly covered with large brown spots; the lip is deep purple-brown, veined with a darker shade of colour. It has the intermediate characters of both parents. From Messrs. H. Low and Co.

Awards of merit were given to the following:—

CATLEYA ADELA (C. Trianae × C. Percivaliana).—This is a distinct and pretty hybrid, having the intermediate form of both parents. The sepals and petals are of fine form and substance, rich rosy lilac, the lip rose-purple, suffused and veined with a darker shade of colour, the side lobes deep purple, suffused with yellow and brown at the base. A small plant with one flower came from Messrs. J. Veitch and Sons, Chelsea.

LILIO-CATLEYA CANHAMIANA VAR. **JOYCE WIGAN.**—This is a distinct and lovely form, the sepals and petals delicate rose, suffused slightly at the margin with a darker shade of colour, the large lip rose-purple, shading to crimson-purple, veined with a darker shade, the side lobes purple, with some yellow and brown at the base. This

lovely form, carrying a raceme of three flowers, came from the collection of Sir F. Wigan.

Messrs. J. Veitch and Sons sent an interesting group, prominent in which were several fine forms of Cattleya Warscewiczii (C. gigas), C. Mendeli, C. Mossiae, and good varieties of C. Warneri. Among the hybrids was the new Cattleya Gertrude (C. superba × C. Mossiae), with the intermediate characters of the two parents both in growth and flower. The sepals and petals are delicate rose, the open lip having a rose-coloured ground, suffused with rose-purple, and veined with a darker shade of purple. Several forms of Lelio Cattleya Canhamiana, a distinct form of L. C. Endora with deep purple lines through the throat, Lalia purpurata, and L. tenebrosa were also well represented. Epiphronitis Veitchi with four spikes of flower, a large specimen of Dendrobium Dearei, Epidendrum vitellinum majus, Cypripedium Veitchi, Masdevallia ignea, Phalaenopsis Ludde-violaeeae with three of its rich rose-mottled flowers, several good forms of Odontoglossum crispum, O. Pescatorei, O. excellens, good forms of Sobralia macrantha, Dsa kewensis, Oncidiums in variety, and Cattleya Harold var. Clarissa (gigas × Gaskelliana) were also included. A silver Flora medal was awarded. Messrs. Hugh Low and Co., Bush Hill Nurseries, Enfield, sent a large group, in which were some large, finely-flowered specimens of Cattleya Mossiae in variety. Grand forms of C. Mendeli, several dark forms of Lalia tenebrosa, a fine variety of Epidendrum prismatocarpum with four spikes of flower, Oncidium crispum and O. macranthum in variety were also well represented. Prominent among the Cypripediums was the beautiful C. Lawrenceanum Hyeatum with two flowers. Several good forms of C. Curtisi, C. eiliolare, and other interesting species and hybrids were also shown. A silver Flora medal was awarded. Messrs. Stanley Mobbs and Ashton sent a neat group, consisting principally of finely-flowered forms of Cattleya Mossiae, including C. M. Reineckiana with four flowers. They also sent several grand forms of C. Mendeli, C. Warneri, Lalia tenebrosa in variety, and good forms of L. purpurata. Prominent among the Odontoglossums were good forms of O. crispum. Miltonia vexillaria was also well represented. A fine form of Mermodes pardinum and good varieties of Epidendrum vitellinum majus, Lycastes, Oncidiums, and Dendrobiums in variety were also included. Stanhopea tigrina var. Ashtonii is a very large variety, the flowers each 8 inches across. A silver Banksian medal was awarded. Messrs. B. S. Williams and Son sent a choice group. In the back row were several finely-flowered Thunia Marshalliana, Lalia tenebrosa, and a grand specimen Aerides expansum with two spikes of flower. There were also several pretty forms of Cattleya Mossiae, C. intermedia, and Lelio-Cattleya Canhamiana. Cattleya Breautiana (C. Loddigesii × C. superba) has bright rose-purple sepals and petals of fine substance, the lip rich crimson-purple in front, white in the centre, with some yellow in the throat. Pescatorea Lehmanni, Cypripedium Lebaudianum, Coeliodia Nozliana, Odontoglossum crispum, and other interesting Orchids in variety were also noted. A silver Banksian medal was awarded.

Sir T. Lawrence sent Masdevallia Barleana, a distinct and pretty form, with rich purple and orange-yellow flowers; Habenaria rhodochilon with green and orange-scarlet flowers, four forms of Lalia tenebrosa, a good form of Cattleya Warscewiczii with seven flowers on the spike, Odontoglossum excellens var. Sanderi, a light form, with unusually large flowers; and Macrostylis bella with two spikes of dark purple flowers. Mr. F. P. White, Twyford, sent Cattleya guttata Leopoldi with thirty-two flowers on the spike. Sir F. Wigan sent Sobralia Wiganae, a natural hybrid in the way of S. Amese; Sobralia Veitchi aurea, a lovely yellow form; and S. xantholeuca. From Mr. De B. Crawshay came Odontoglossum excellens Mrs. De B. Crawshay, a yellow and deep brown blotched variety favouring

O. triumphans, and a lovely dark form of Cattleya Mendeli named after himself. Mr. W. Gillett, Fair Oak, Bishopstoke, sent a dark form of Lalia purpurata with six flowers on the spike. Mr. Leopold de Rothschild showed Mermodes pardinum unicolor, and from Mr. T. W. Swinburne came two large flowers of Sophronitis grandiflora. The Rev. E. Handley, Bath, sent Cattleya Mossiae Wagneri with two flowers, and Mr. F. W. Moore, Glasnevin, showed three very interesting and beautiful forms of Masdevallia Chimara.

Floral Committee.

The following plants obtained first-class certificates:—

CAMPANULA MIRABILIS.—A distinct and striking species, producing a more or less pyramidal panicle of pale blue erect cups in great profusion. A marked feature of the plant is the fleshy, shining, slightly toothed leaves, which before throwing up the flower-spike form a perfectly flat rosette close upon the earth. It is possible it will prove biennial in character and in size be much larger generally than the plant exhibited. From Messrs. G. Jaekman and Sons, Woking.

LILIUM MARIAN.—A hybrid Lily of great promise, the parents being L. Hansonii and L. Martagon var., probably dalmaticum. In the time of flowering, together with size of blossom, form and other characteristics, there is a marked presence of L. Hansonii, with the decided fragrance of L. Martagon var. The colour is a brownish bronze overlying yellow, and freely spotted with dark spots. From C. G. van Tubergen, Haarlem, Holland.

The following received awards of merit:—

NASTURTIUM QUEEN OF TOM THUMBS.—As shown this is very dwarf and compact, with flowers of a deep crimson-brown. The foliage is freely variegated. From Messrs. Watkins and Simpson, Long Acre.

DIGITALIS PURPUREA GRANDIFLORA.—This strain is remarkable for the boldness of its spikes, the size of its blossoms, and the markings on the same. From Messrs. Jas. Veitch and Sons, Chelsea.

PHILADELPHUS LEMOINEL.—A pretty shrub covered with a wonderful profusion of snow-white and fragrant blossoms, every twig being laden with flowers. From Messrs. Barr and Sons, Covent Garden.

BEGONIA FLORENCE NIGHTINGALE.—This is a really marvellous flower even as tuberosus Begonias go, the blooms of the purest snow-white, of great size and well formed. Some of the handsome double flowers were more than 5 inches across, besides which it is quite dwarf and very free. From Mr. B. R. Davis, Yeovil, Somerset.

BEGONIA THUNDERER.—A massive crimson-scarlet, the flowers almost as large as those of a Paeony, very full and well built to the centre. The habit was very dwarf and free in all the plants shown. From Mr. B. R. Davis, Yeovil, Somerset.

GAILLARDIA W. B. CHILD.—A large and handsome variety with self-coloured flowers of a chrome-yellow shade. From Messrs. Kelway and Sons, Langport.

LUPINUS POLYPHYLLUS SOMERSET.—In this kind we have, as it were, the yellow spike of L. arboreus transferred to a herbaceous kind, viz., L. polypphyllus, which should render it of much value in the garden. The pretty soft yellow is particularly telling. From Messrs. Kelway and Sons, Langport.

IRIS JUNCEA SCINDICA.—A lovely pale yellow variety of I. juncea (the Rush-leaved Iris), a bulbous species belonging to the Niphium group. The kind now referred to is a dainty and pleasing variety that cannot fail to be welcome. From Messrs. R. Wallace and Co., Colchester.

ROSE UNA.—A hybrid between R. chinensis and R. indica, resulting in a large and handsome single white kind, each flower 4 inches across, quite pure when expanded, but having a creamy tint on opening. A single shoot of this new hybrid, the first of its race, measured just 25 feet

long, and as a climber it will doubtless prove of great value. From Messrs. Paul and Son, The Old Nurseries, Cheshunt.

ROSE REV. ALAN CHEALES.—An H.P. kind with large, handsome blossoms of a lively rose shade and silvery reverse. The flowers are very full and delightfully fragrant. From Messrs. Paul and Son, Old Nurseries, Cheshunt.

HEDYSARUM MULTIJUGUM.—An old-fashioned and well-known plant, producing a profusion of purple Pea-shaped blossoms during spring and autumn. A coloured plate of this was given in THE GARDEN, May 14, 1898, p. 408. From Sir Trevor Lawrence, Dorking (gardener, Mr. Bain).

GLADIOLI'S QUEEN OF ROSES.—This is one of the dwarf early-flowering class (*G. nanus*), of which Blushing Bride and Salmon Queen are representatives. The above has flowers of an exquisite and delicate pink, almost flesh-pink, very beautiful and pleasing. From Messrs. Sutton and Sons, Reading.

CARNATION MRS. DE SATGE.—Scarlet; very full and of good colour.

CARNATION LORD WELBY.—Scarlet of a somewhat lighter shade; very handsome.

CARNATION MARGOT.—Pinkish scarlet, somewhat in the way of Princess May; excellent in form.

CARNATION BALDWIN.—Salmon-rose; a very handsome flower. All of the above Carnations came from Mr. Martin Smith, Hayes, Kent.

One of the leading features of the exhibition was a splendid group from Lord Aldenham, Elstree (gardener, Mr. E. Beckett), which extended half-way down one side of the hall. The group was admirably arranged without crowding of any kind, prominent positions being accorded to handsome Kentias, *Areca lutescens*, &c., which threw a canopy, so to speak, over the other plants, which comprised various Crotons, beautifully coloured, many *Dracenas*, *Malmaison Carnations*, *Crassula coccinea*, *Odontoglossum crispum*, *Gloxinias*, such *Liliums* as *longiflorum*, *speciosum rubrum* and *Krautzeri*, *Tuberoses*, yellow Carnations, *Asparagus*, *Gladioli* The Bride, with Ferns, *Panicums* and *Isolepis*, the latter employed as a fringe to a very telling arrangement, for which a silver-gilt Flora medal was awarded. The Roses from Messrs. Wm. Paul and Son, Waltham Cross, were a most representative gathering, containing nearly 100 varieties, and embracing almost all sections of the flower. Dwarf bush plants, standards, and endless examples in a cut state were shown, many in large groups in baskets that proved very effective. A few of the best were *Narcisse*, pale cream yellow and white; *Mme. Falcot*, the lovely hybrid Tea *Caroline Testout*, Wm. Allen Richardson, *Marie Lavallée* (Tea), a lovely pale pink; *Empress Alexandra* of Russia, perhaps the most prominent by reason of its size and colour, a lovely bronze-salmon tone; *Enchantress*, *Souvenir de Catherine Guillot*, coppery salmon, very charming, quite a novel shade among Teas; *Antoine Rivoire*, *Queen Mab* (China), deep salmony orange, a most lovely shade; together with many singles, Mosses, *Polyantha* kinds, &c.—a truly sumptuous lot of these beautiful flowers (silver Banksian medal). Some ten varieties of hybrid Water Lilies from Mr. Leopold de Rothschild, Gunnersbury House, Acton (gardener, Mr. Jas. Hudson), attracted much notice. These included *Mariaacea rosea*, *M. albida*, *M. Chromatella*, one of the most useful and beautiful of all; *M. carnea*, *Laydekeri lilacea*, *Ellisiana*, crimson, rich in colour and beautiful in form; *stellata*, blue, &c. These were grouped in a shallow vessel of water, thus keeping perfectly fresh throughout the meeting (silver Banksian medal).

A group of *Adiantums* representing some ninety species and varieties came from Mr. H. B. May, Edmonton, and constituted a most instructive lot. It is not possible to enumerate or describe so representative a collection. *A. Hemsleyanum* is certainly among the most graceful and elegant, and *Lambertianum* has the most minute pinnae of all, considerably smaller than in *gracillimum*. *A. Veitchii* is very striking in the young fronds, and

withal a handsome kind. *A. Forearum* has a silvery sheen over the mature fronds and a red-bronze tone in the young pinnae which render it attractive. *A. fulvum* is all its name implies; while *reniforme asarifolium* has the broad foliage of the latter plant very strongly suggested. *A. Capillus-veneris imbricatum*, with its densely set fronds overlapping each other, is very distinct. A silver-gilt Banksian medal was awarded. *Begonias* were well represented, Mr. B. R. Davis, Yeovil, Somerset, bringing a splendidly grown lot of plants of very dwarf habit and bearing a profusion of giant blossoms in rich and telling shades and much variety—*Venus*, pure white; Wm. Allen Richardson, orange; Mrs. Stothbert, soft yellow; Trafalgar, orange blossoms; *Clio*, yellow goffered petals; and *Orion*, brilliant scarlet, enormous double flowers, being among the most conspicuous in this finely-grown lot of plants (silver Banksian medal). The other group, from Messrs. Cannell and Sons, of Swanley, contained many fine things, such as *Lady Lonsdale*, orange; *The Lady*, white; *Paul Hardy*, crimson; *Jean Sisley*, deep crimson; and *Brilliant*, intense velvety crimson (bronze Banksian medal). Carnations in pots, largely of the *Malmaison* section, were as strongly represented as we usually see them at the Temple show. The large semi-circular group of the pink variety shown by the Marquis of Salisbury, Hatfield (gardener, Mr. George Norman), was as fine as it is possible to be, more especially as the plants were bearing a maximum of flowers, and that quite small plants in 6 inch pots carried an average of four handsome blossoms. Some idea may be gathered of the display of bloom when it is stated there were some 200 of these plants, with something like a total of 1000 of these noble flowers. Such groups as this demonstrate that freedom of flowering may be—indeed, is—secured without the use of huge pots and much soil, which may after all too much favour gross growth at the expense of flowers. The group from Hatfield was a highly creditable lot, well deserving the silver Flora medal awarded. Another group, in which greater variety prevailed, the plants arranged in undulating banks usually of one colour and kind, came from Messrs. Cutbush and Sons, Highgate. Here also the small pot system prevails, though in many instances disbudding had been resorted to, the blossoms being larger and less numerous than in the last instance. Many beautiful varieties were in this group, such as *Princess May*, *Churchwarden* (crimson), *Prime Minister* (scarlet), *Princess of Wales*, *Mme. Adeline Patti*, fine pink, with a large batch of the old Blush kind. A few border kinds were also included, an especially good form being *Andrew Noble*, a reddish salmon (silver Flora medal). Another group of *Malmaisons* was made up entirely of novelties by Mr. Martin R. Smith, Hayes, Kent (gardener, Mr. Blick). Some of the best are noted elsewhere, but other good kinds are *The Geisha*, salmon-rose; *Trumpeter*, crimson-scarlet; *Nautilus*, white; *Juliette*, scarlet-rose; *Mrs. Torrens*, fine deep pink; *Calypto*, blush, very fine; while a yellow border kind, *Cecilia*, in the background was little, if any, inferior in point of size to many of the *Malmaison* kinds. A silver-gilt Banksian medal was awarded. Messrs. Peed and Sons, Roupell Park, likewise contributed Carnations, mostly border kinds, grown in pots—*R. H. Measures*, scarlet; *Primrose* (Queen, J. W. Christmas, reddish pink; *Rosamond*, salmon-scarlet; *Miss Measures*, crimson-scarlet, being among the best. These, with a margin of pink *Malmaisons*, were still further bordered by *Athericum lineare variegatum* (silver Banksian medal). Mr. F. G. Foster, Brookhampton, Hants, had a fine assortment of Sweet Peas in many beautiful shades disposed in a very pleasing manner—*Countess of Aberdeen*, flesh; *Meteor*, rosy salmon and bronze; *Peach Blossom*, *Queen Victoria*, yellowish white; *Celestial*, *Lady Nina Balfour*, soft mauve; *Black Knight* and *Countess of Radnor*, rosy mauve, being among the best (bronze Banksian medal). A small batch of *Phonocoma proliferata* Barnesi, more naturally grown than is

usually seen, from Messrs. Balchin and Sons, Hassocks, displayed the value of such well-grown plants, and the finely-flowered heads were most attractive.

Hardy flowers, as at the previous meeting, held the place of honour on this occasion, not merely in point of numbers, but in quality also. The *Pæonies* and *Delphiniums* from Messrs. Kelway, Langport, were excellent in every way, the best of the former being *Dai*, pink-blush; *Ganymede*, crimson, centre tipped gold; *Olivia*, pure white; *Chiron*, crimson; *Miss Salway*, creamy white; and *Visticus*, pure white, double; while of *Delphiniums*, *Primrose* and *Beauty of Langport* represent all that exists of so-called white kinds, though we feel constrained to confess the shade of colour is a little out of place among these noble showy flowers. Among the blues, *Truc Blue*, *King of Delphiniums*, azure-blue, immense white centre; *Dagonet*, dark purple-violet; *Alfred Henderson*, *Ardite*, and *Imperial Majesty*, rich purple-violet, were the finest. Other plants shown were *Gaillardias* in variety, *Centaurea macrocephala*, *Inula glandulosa*, *Phlomis Russelliana* with whorls of yellow and white flowers, several *Eryngiums*, double white *Rocket*, *Campanula persicifolia maxima* and its variety *alba*, both in splendid condition and very showy (silver Flora medal). Messrs. Jas. Veitch and Sons showed herbaceous *Pæonies*, in bold effective masses for the most part. Some of the leading sorts were *Pottsi superba*, crimson-lake; *grandiflora rosea*, *Emilie Lemoine*, white, slight crimson flake; *Duchesse de Nemours*, white; *Leda*, rosy pink; *delicatissima*, pink; and *Carnea triumphans*, &c. Then in *Delphiniums* we noted *Bach*, *Lucifer*, the lovely sky-blue *Belladonna*, *Keteleeri*, an old though showy kind; *Princess of Wales*, azure-blue; *Lord Balfour*, violet-purple, &c. These were margined with flowering branches of *Tropæolum polyphyllum*. At one end of the table, which extended the full length of the centre space, a host of annuals and biennials was arranged—such things as *Sweet Peas* in variety in all the best kinds, together with *Wallflowers*, *Stocks*, *Sweet Sultan*, *Carnation Grenadin*, *Rhodanthe*, *Clintonia elegans*, with its blue and white flowers, *Schizanthus retusus* and its variety *albus* also being abundantly shown. Then in the centre were vases of annuals, such as the white *Schizanthus*, many *grasses*, *Sweet Peas* and the like, that made a very pleasing array. The same firm set up a fine lot of *Campanula Medium calycanthema*, the whole of the plants splendidly grown and branched with a freedom but rarely attained in pots. The plants were all grown in 8-inch pots, and grandly flowered throughout. The size of the flowers individually was alone a feature. The firm brought also the usual complement of rare flowering shrubs, among which *Magnolia Watsoni* was very fine. Other things included *Indigofera decora alba*, a most graceful thing; *Styrax japonica*, white, abundantly flowered; *Philadelphus coronatus erectus* and *Escallonia langleyensis*, a red-flowered kind, very profuse (silver Flora medal). From Colchester, Messrs. R. Wallace and Co. sent a lovely lot of hardy bulbous things that included *Liliums* in plenty, notably the lovely new kind *L. rubellum*; also *L. Hansonii*, *L. Szovitzianum*, *L. tenuifolium*, *L. pomponium verum*, *L. pardalinum*, *L. Dalhansonii* (a handsome hybrid), *L. Henryi*, together with a large assortment of the forms of *L. Thunbergianum* and the more stately and massive flowers of *L. platyphyllum*, *L. rubro-vittatum*, *L. Wittei*, with three of its superb white, spotted flowers only relieved by a chrome-yellow band in the centre of each petal. Besides these were many *Brodiaeas*, various *Calochorti*, *Ixias* in variety, *Hemerocallis aurantiaca major*, English and Spanish *Iris*es, *Iris gigantea*, *I. Monnierii*, and the lovely bulbous *Iris I. juncea* (silver Banksian medal). The Messrs. Barr and Sons likewise had one of their usual displays of hardy things, among which *Pæonies* largely figured, also *Iris*es of several sections, such as English and Spanish, and the distinct *Iris Monspur* and varieties, which are very beautiful and distinct. This exhibit also con-

tained such things as *Papaver nudicaule*, several Sea Hollies, Pink Her Majesty, very fine *Lupinus arboreus*, *Ornithogalum pyramidale*, *Inula glanulosa*, *Dictamnus* of sorts, *Ranunculus asiaticus* in variety, &c. (silver Banksian medal). Messrs. Paul and Son, The Old Nurseries, Cheshunt, also staged a splendid lot of herbaceous Paeonies and Delphiniums in all the leading kinds in both instances, together with many vases of the new single Rose Royal Scarlet in the bud state (silver Banksian medal). Another group of hardy flowers from Messrs. Geo. Jackman and Sons, Woking, contained many Campanulas, Delphiniums in variety, Sweet Peas, Pyrethrums, Heuchera, *Lychnis Haageana*, some *Eryngiums*, double yellow Bachelor's Buttons, *Sidalcea malvaeflora*, &c. (bronze Banksian medal).

Fruit Committee.

The exhibits before this committee, though not numerous, made up by their splendid quality. A first-class certificate was given to—

PEACH THOMAS RIVERS.—It is a very beautiful fruit, large, and of a splendid colour, skin pale mottled pink, with very little green, the flesh of great thickness and juicy. It is a splendid addition to this class of fruit. The fruits shown were from pot trees started on December 20.

Mr. Gleeson, Warren House Gardens, Stanmore, staged nine Queen Pine-apples, splendid fruits and with very small crowns. One was shown as a new variety, but the committee could detect no difference. A silver-gilt Knightian medal was awarded. Mr. Hudson, Gunnersbury House Gardens, Acton, sent a large quantity of Tomatoes, and Cherries Early Rivers and Bigarreau de Sebren. The Tomatoes were in six varieties. The fruits were tested for flavour, and Royal Jubilee was considered excellent, Golden Nugget and Sutton's Dessert being of equal merit as regards quality. The other varieties were Abundance, a beautiful fruit, Peach Blow, and Best of All, the last named a medium-sized fruit of great excellence. We do not care for the colour of Peach Blow, though it does not lack flavour. A silver-gilt Banksian medal was awarded. Some excellent Tomatoes were sent by Mr. Rolfe, Stamford-le-Hope, Essex, the flavour being liked and the fruits very shapely. These were named Rolfe's Challenge. The committee had an excellent opinion of their quality, but as plants are growing at Chiswick, they wished to see the cropping qualities before giving any decision as to their merits. Messrs. Veitch and Sons, Ltd., Royal Exotic Nursery, Chelsea, sent baskets of Cherries Guigne d'Annonay from pyramid trees in the open. This variety was stated to be some days earlier than the Early Rivers, and it appears to be very prolific, the fruits of a dark red colour, being in large clusters. Royal Sovereign Strawberries gathered from the open ground, from plants layered last July, were staged by Mr. Wythes, Syon House Gardens, Brentford, to show the advantages of growing the Strawberry as an annual, as the fruits are earlier, finer, and of excellent quality. A very good seedling Melon was sent by a Mr. W. Coates, but there was no address. Unfortunately, the fruit was not ripe, but the committee desired it to be sent again. A new seedling Pea, Early Queen, was sent by Mr. Edwards, Grove Lodge, Guildford. This the committee asked to be sent to Chiswick, as it is impossible to test Peas unless the growth is seen.

The weather in West Herts.—During the past week there occurred but one unseasonably warm day, when the temperature in shade rose to 73°. The nights, taken as a whole, were also cold for the time of year, and on that preceding the 26th the exposed thermometer fell to within 4° of the freezing point. Both at 1 foot and 2 feet deep the ground is now of about seasonable warmth. Rain fell on five days during the week, and to the aggregate depth of nearly three-quarters of an inch. No measurable quantity of rain-water has now come through the light soil percolation gauge for over three weeks. The first

Hybrid Perpetual Rose came into flower in the open ground in my garden on the 25th, which is eight days later than the average for the previous 12 years, and later than in any of those years except 1888.—E. M., *Berkhamsted*.

PUBLIC GARDENS.

PRIVATE GROUNDS AND THE PUBLIC.

No more specious measure, perhaps, was ever introduced into the House of Commons than the "Access to Mountains" Bill. Under the guise of an artist, a botanist, or an admirer of Nature, the tourist was to be allowed to roam over grouse moors and deer forests, possibly to his own delight, but to the undisputable confusion of the man who paid a large rent for the right of sporting over the ground. Farmers, too, were opposed to the measure, as the tourists and their dogs would have much disturbed the sheep. Putting aside the fact that a succession of trippers would have completely put an end to that quiet which is so necessary for moors, forests, and sheep farmers, we urged, on each occasion of the Bill being introduced, that many of those who would have taken advantage of its provisions, had it become law, would certainly not have comforted themselves as sober artists and botanists should. Eggs, if found, would doubtless have been abstracted if any tourists were abroad in the nesting season; while other damage would have been committed to the detriment of the owner of the shooting; for it has long been notorious that some people will abuse the privileges extended to them. Of this we have a very recent instance. The Earl of Malmesbury had for some time been accustomed to throw open his beautiful Rhododendron forest at Heron Court, near Bournemouth, to the public; and to wander there was a treat which could not be otherwise than highly appreciated by numberless visitors to that seaside resort and the district. Then the order went forth that the public were to be excluded, and it is only the other day that a daily journal stated the regret expressed that Lord Malmesbury still continued to close the forest against strangers. This note brought forth a reply from the owner of Heron Court, "No one," wrote the Earl of Malmesbury, "regrets it (the closing of the forest) more than I do; but I had no alternative, owing to the behaviour of visitors from Bournemouth, who set law and order at defiance and my woods on fire." Here is a pretty indictment against tourists, holiday-makers, and others who aforesaid availed themselves of being allowed to enter private grounds; yet nobody who knows the country well will say that Lord Malmesbury has been guilty of the least exaggeration. It is a common enough saying that property has its obligations as well as its rights, and, up to a certain point, the saying is true. As a rule, we venture to think, no one realises this more than those who own large and picturesque parks, and in different parts of England houses and grounds are thrown open, under certain proper restrictions, to the public; but it is unpleasant to relate that people will get out of the way of the cicerone or attendant to commit some petty damage.

Many years ago, Lord Hill's fine park at Hawkestone, in Shropshire, was thrown open to the public, who were allowed to picnic therein; but the concession was so far abused that broken bottles were left about, with the result that both horses and deer were lamed; so the public were no longer allowed to take provisions with them, but were obliged to make their meals in an hotel which was built at the entrance to the park. It should surely not require much thought to cause people to remember that broken glass left lying about must be a source of great danger to human beings as well as to animals; and when Oxford races were held on Port Meadow there were in most years accidents arising from this very cause for some days after the racing was over. Private parks and gardens cost a good deal to keep up,

and the privilege of walking in them is highly valued by all, careful and careless alike; and, while it must be admitted that there are not a few careless and dishonest visitors, there are at the same time many who are careful not to do any damage. Many owners make a charge for viewing show houses and grounds, dividing the receipts among local charities and charitable institutions. This, of course, to some extent does away with the presence of the objectionable class, but not entirely; for complaints have been made of damage by several owners who do make a charge. Anyone who finds his woods, his grass, or his gorse fired, may well feel annoyed at this return for his kindness, and no one need be surprised if he closes his doors to casual visitors, as the Earl of Malmesbury has been compelled to do, in consequence of the loss he has suffered by his plants and trees being injured and his woods set on fire. There is in Devonshire a show house, in which the one piece of furniture was a fine old Oak chair, and round the house visitors were allowed to ramble free from any restraint. Twenty years ago or more so many names were cut on the chair that there was room for no more; and this habit of disfiguring everything that can be cut or scratched is one of the curious freaks of the holiday maker and tourist, who think that no place which they may have visited is properly honoured unless it bears their names. There are people who steal flowers from the graves and borders in cemeteries; while the public parks in London and elsewhere are not free from the pilferer; readers at the British Museum have been known to mutilate books—in short, wherever people have access to something with which they cannot provide themselves, in a large number of cases they deliberately set themselves the task of doing injury and wrong. The picture galleries and libraries of some of the great London houses have been occasionally thrown open on Sunday afternoons, and in one or two cases some slight injury to something has subsequently been discovered. It is hardly possible to over-estimate the enjoyment to hard-worked people of going for recreation, not into a desolate open space or a disused burial ground, but into a well kept private park, or into a comfortable private gallery, instead of bare public rooms; but the misdoings of a few cause the *entrées* to be denied, and, in the emphatic words of a contemporary, and quoted by Lord Malmesbury, "The British public has to suffer for the behaviour of the British cad."

Sauce for the goose is proverbially sauce for the gander, and we have purposely laid a good deal of stress on the fact that those gentlemen who do their best to add to the pleasure of the poorer members of the community have every right to expect that, in return for the concessions they make, respect shall be shown for their property and convenience. If this respect be not shown, the place is closed, as has been Lord Malmesbury's Rhododendron forest, and several other places. But on the sauce for the goose and gander question, how about the farmer who finds that his concessions are abused? The owner of the park which is closed against visitors simply warns them off; but farmers have to be more long-suffering still. Year after year they see their crops ridden over—not by those who go field for field with hounds, but by those who are half a mile behind the pack. They see their gates left open, their fences gapped by those who have not the pluck to ride boldly at them, and they find people taking short cuts over their land when going to the covert side or returning home after hunting. In noting these matters, we are very far from saying that private parks and gardens should not be closed against wanton visitors; still less do we invite aggrieved farmers to warn hounds off their land because they have suffered a certain amount of injury at the hands of the thoughtless. The real subject of the moral is the hunting man himself. He, at least, should not be blind to the fact that if the owner of an estate is justified in closing his grounds to an uneducated class because of the damage its members do, the farmer would be equally justified in keeping

out the gentlemen in tops and scarlet, who really inflict far more injury than do the tourists and holiday-makers to the private grounds of noblemen and gentlemen. Those who come out of the slums may almost be pardoned if, in their pleasure at finding themselves amid new surroundings, they in their ignorance or thoughtlessness commit some wrong; but little can be said in extenuation of the man who goes out hunting and violates almost every canon which is supposed to govern the sportsman. Hospitable persons who entertain men on their way home after hunting know quite well that their guests will allow their horses to plant their feet on the edge of a grass plot, or even on a flower border; and this we have ever maintained is quite as great an offence as any which is committed by those who damage property over which they are allowed to walk.—*Field.*

The proposed extension of Hampstead Heath. The freehold estate of the late Sir T. Spencer Wells, known as Golder's Hill, Hampstead Heath, has, we learn, been sold for £38,500. A movement is on foot to secure the estate for the public as an extension of Hampstead Heath if the necessary funds can be raised, and it is understood that the purchaser is open to deal with the property from that point of view.

NOTES OF THE WEEK.

Epiobium obovatum is a dainty little rock plant from California, forming a spreading mass close upon the ground, and freely furnished with large open rosy-purple blossoms. The plant flowers for some time during summer, and prefers a warm, well-drained position on sunny rockwork.

Erigeron glaucus.—This handsome composite has been in full flower for more than a month, and is remarkable for the longevity of the blossoms, which are large and very showy. The florets forming the rays vary from a distinct lilac-blue to a reddish lilac hue, the leaves slightly clammy and entire. The spreading habit ultimately assumes a procumbent form that renders it quite distinct from other species of the genus.

Polygonum baldschuanicum.—When seen thickly studded with flowers and at a slight distance, this plant strongly resembles a cloud of foam, sufficiently so to entitle it to bear the term Foam Bush, the bunches of blossoms hanging around the twiggy branches of which the plant is composed in great abundance. It is a pretty climber of a sub-shrubby character, breaking and flowering with remarkable freedom from the old twigs or branches. A fine example of this is now in excellent condition in the Royal Gardens, Kew.

Sparaxis pulcherrima alba.—The typical species is fairly well known, although it is by no means a plant which flowers regularly in the open in this country, but the white form as cited above is much more rare. It is, however, a chaste and beautiful flower, singularly graceful and elegant in its bearing, by reason of the thin, almost wiry, nature of the long arching spike that bears its blossoms in profusion for a long season where a good cluster exists. An excellent white-flowered variety is now in bloom on a warm border at Kew.

Iris tectorum.—In reply to the note in THE GARDEN of June 18 (p. 521), I may say that for the first time since I received it, several years ago, *Iris tectorum* is not flowering. The plant on the roof garden is apparently quite thriving, but I fear that I have it in too exposed a position. It is close to the apex of the roof, where it gets more than a due share of the cold winds. It is, however, perfectly hardy in this position, but I am removing it lower down, where it will have as much sun with a warmer situation.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Chrysanthemum leucanthemum semiduplex.—This, although not an absolutely new plant, is pretty enough to deserve to be more widely known. Its distinguishing feature is the number of narrow ray petals arranged in a loose and informal way between the ordinary rays, as

seen in the typical plant, and the yellow disc. This gives it a very light and graceful appearance, which adds to its value as a garden flower or for cutting. It is quite hardy and perennial, and increases rapidly. In the light soil here it is always very pleasing.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Dianthus callizonus is among the choicest of the Pinks and worth special care to make it a success. In point of size it may be compared with the more tufted *D. alpinus* or *D. neglectus* when these are of large size, and of richer colour than either. The large solitary blossoms, however, are produced on leafy stems that are 3 inches or 4 inches long, the tuft of leaves decidedly more spreading than in the other kinds named. A patch of this covered with its handsome flowers would form a charming picture, and coming as a close succession to other species invests it with additional value. A coloured figure of this appeared in THE GARDEN of October 10, 1891, p. 332.

Baptisia australis.—When well grown and fully established this plant is very effective either in the border or in isolated positions on the grass. It is, however, a plant too rarely seen in good condition, for not only is it distinct in its flowering and among perennials unique in early summer, for it makes quite a handsome bush of its slightly glaucous leaves and attains nearly or quite 4 feet high and as much through. Indeed, there is just such an example at the present time flowering in the herbaceous ground at Kew and bearing quantities of its metallic blue flowers on stout stems. The plant is of easy culture in good ordinary soil, but it requires to be left alone in order to attain its full size.

Saxifraga cochlearis.—This is, perhaps, the finest of all the crusted Saxifrages in bloom at the present time, the snow white flowers but very faintly tinted with pale pink spots, so pale as not to be seen at a little distance off. Its beauty, however, is very marked where a small colony has been established, as it is among the most free flowering of its race, the purity of the blossoms appearing to even better advantage against the reddish-coloured stems and peduncles. Unfortunately, this plant is not always to be obtained true to name; indeed, confusion exists with both this and the "minor" form, the latter being most frequently sold as *S. valdensis*. The above kind is about a foot high when in bloom and very dainty in its general appearance.

Campanula pulla.—This is always a most welcome member of the Bellflower family, the elegant drooping blossoms depending from a fragile stem that is arched in the most distinct manner. There is a richness in the colour in this charming plant that is not equalled by any other species. For the growth and general habit of the plant the flowers are much larger than in any plant of similar stature, and the blossoms borne singly on the stems may to some extent account for this. The rich dark purple bells are now very effective. I do not know if there is more than one recognised form of this lovely Austrian Hairbell, but in the plant now referred to the flowers expand somewhat at the mouth, while in another instance noted a few days since this is quite wanting.

A new Lily.—"S. W. F." remarks on p. 550 of THE GARDEN for June 25 "that if *Lilium rubellum* (exhibited at the Temple show) should prove hardy it will be a most valuable addition to the flower garden." It therefore may be of interest for him to know that I received some Lily bulbs from Japan last year marked "New kind of Lily, Kramer variety." They were at once planted in an open border with a south aspect, in warm, light soil, and have been in flower for several days. From the illustration and description in the *Gardeners' Chronicle* for May 28 there is no doubt they are *Lilium rubellum*. Of course, last winter was unusually mild, still the late spring weather has been most unfavourable to many hardy plants, and I should say this new Lily will prove quite hardy and easy to grow in ordinary garden soil. Those now in flower here have from two to three pretty pink

flowers on a stem, which last for some time without losing their colour.—E. M. WEBB, *Nottingham.*

Cypripedium spectabile.—The most valuable of all hardy Cypripediums is the above, and one which is now flowering freely. Its chief value, apart altogether from the beauty of its handsome flowers, is due to the ease with which it may be grown in cool and shady spots in almost any garden, and also to its perfectly reliable character where given proper cultivation. This is more, perhaps, than could be stated of the majority of the hardy species. Given a moist, peaty bed, where a constantly cool rooting medium is guaranteed, and with good plants, one may rest fairly well assured of the plants becoming stronger and better each year. Size and general vigour may be increased if a specially deep bed of peat is given, to be followed each autumn by a mixed mulch of decayed leaves, peat, and very short, finely sifted manure. The last is not usually applied in planting this Orchid at first, but it may be supplied in the manner suggested and with good effect.

A note from Homburg.—There are many trees grown here that one seldom sees in English gardens. Four of them are particularly handsome. One is the American Silver Lime (*Tilia alba*). This variety has leaves of a darker green and larger than the common Lime, the under part being silvery-white. The leaf-stalks being long, the under-side is often turned to the front, and the mixture of green and silver has a very pleasing effect. The flower-pods, not yet open, resemble those of our native kind. I do not know if they are equally sweet scented. *Salix vitellina aurea pendula* is a much handsomer tree than the Babylonian Willow, being perfectly hardy, having the same habit, and much longer branches. *Aurea* only refers to yellow twigs; the leaves are green. The Babylonian Willow, so often extolled for its graceful beauty, has one great defect for a northern climate; it is sub-evergreen. The first early growth begins in February, and seldom escapes a spring frost. Its beauty is not developed until late in July, if then, when it has made a second start. Anyone who doubts this should now visit the upper parts of the Thames, where these trees abound, and he will see how shabby the universal favourite looks at this season. Here, being near the variety I have mentioned, the two can be compared. *Acer pseudo-platanus erythrocarpum* is a Sycamore with pretty scarlet keys. The fourth tree is a Maple with dark green leaves when perfected; the young shoots are bright red. This tree is planted on either side of a street, and is very showy when the sun lights up the young red leaves. I do not know its right name. A winter in North Germany must be, as far as outdoor gardens go, rather dreary, as evergreens are few and far between; they cannot stand the severe cold. Even Aucubas and Laurels, which are planted *ad nauseam* at home, are grown here in tubs.—J. H. W. THOMAS.

Water weed pest (*J. Matheson*).—The weed sent is a species of *Chara*, a pest that propagates itself abundantly. The following remedies for its destruction have been effectual in many cases: (1) Drain the pond or lake, clean out the mud, and when the bottom is dry pitch it with a layer of chalk. (2) Drain and dry the bottom, and water by water-cart with a strong solution of carbolic acid. (3) Clear out the bulk of the weed with rakes or drag-chains, and keep swans and other water fowl in order to keep it down. The feeding source should be carefully guarded against the ingress of water weeds, but in the case of this weed as well as the Canadian Water Weed the smallest scraps (often carried from lake to lake by water fowl) will increase, as well as by the spores and seeds the plants produce.—G.

Names of plants.—*Henry Shaw*.—1, *Angulora uniflora*; 2, *Odontoglossum Ruckertianum*; 3, *Epidendrum ciliare*.—J. S. S.—*Polystichum vestitum*.—L. Burnett.—1, *Trifolium resupinatum*; 2, *Sisymbrium Iri*.

THE MARKET GARDEN.

GOOSEBERRIES IN KENT.

As is well known, Kent is the principal centre of commercial fruit culture, and, owing to the varying conditions of soil and situation, the county may be divided into sections, each producing its own fruit. One district is the favoured home of the Strawberry, from another more Raspberries are produced than from any similar area in the kingdom, and a third is noted for its Cherries. Kentish Cobnuts flourish in the brashy soil on the gently sloping hill-sides, where other fruit will not grow satisfactorily, and in rich fertile districts Apples, Pears, and bush fruits grow to perfection. It may sound strange to hear of any particular area being noted for Gooseberries, for in every garden in the kingdom this popular fruit is found. This seems to point to the fact that the Gooseberry is an accommodating fruit without any particular fancy for soil and situation, yet it is only in a few places where the cultivation of Gooseberries is treated as an industry. In private gardens the Gooseberry quarter is generally in a sheltered position and necessarily limited in extent, but in Kent Gooseberries are grown in the open fields by the acre, and it is from these favoured districts that the tons of fruit that find their way into all parts of the metropolis and other great centres of population come. Anyone travelling by road from Canterbury to Sandwich may, by leaving the main thoroughfare and threading through the little villages that lie on either side, pass into one of the centres of commercial Gooseberry culture. It is not the only one in Kent, as other districts are similarly noted, but here the deep sandy loam grows corn and Hops as well as bush fruit to perfection, and an hour could not be more pleasantly spent than in the plantation of a Kentish fruit grower who is interested in his occupation.

Many of the growers are freeholders and own their own plantations, varying in extent, but

giving an idea of the returns that must be obtained from a small area of land to pay percentage on capital, wages, expenses, as well as provide a livelihood for the occupier. When I was in this neighbourhood a few weeks ago Gooseberry picking had just commenced, and women and girls were gathering the fruit and depositing it into the round sieves to be dispatched to the London markets. The Gooseberry crop is an important one on account of the two seasons of picking, and when the bushes are well laden, as is the case this season, the first picking is done as soon as the fruit is large enough. This takes the form of a thinning, as, except in a few cases, the bushes are not entirely stripped, but simply eased of their burden, so that the remainder of the fruit may develop for gathering in a ripe state for preserving. I learnt that prices have been low this season, no doubt owing to the heavy crop.

PESTS.—This season the bushes have a clean, healthy appearance, and the deadly caterpillar has generally been conspicuous by its absence up to the present. The Kentish grower has many enemies to contend with. The county abounds with the feathered tribe, and early in the spring they play havoc with the buds. In many villages sparrow clubs are formed for the extermination of the pests, against which regular crusades are made by members of the clubs. Great differences of opinion exist as to the damage done by birds. One grower will tell you that they are a nuisance, and another in the same village takes no trouble to destroy them, asserting that they do nothing worse than thin the buds. The caterpillar in some seasons is a plague, and a plantation badly affected presents a pitiable appearance, with the leaves stripped to skeletons in a few days unless stringent measures be taken to check the onslaught. Another pest more difficult to destroy than the caterpillar is the Gooseberry mite, which causes the bushes to assume a sickly yellow appearance. During the dry weather of last season it was very common, and caused the death of many old bushes. A

grower informed me that he would not keep old Gooseberry bushes, as they only encouraged the mite, and as soon as they began to show signs of decay they were grubbed up and the ground given a change of crop. By judicious arrangement the plantation may consist of sections containing bushes of various ages, so that when one is done away with the loss is only slight, as there is another ready to take its place. When bushes are marked for grubbing up they are not pruned, but allowed to carry as much fruit as possible, and all this is gathered green, after which the bushes are at once destroyed.

PRUNING in the early spring is an important operation, some men being very expert at it. Kentish growers generally have firm faith in proper pruning, and one may readily observe that the largest quantity of the finest fruit is obtained from plantations where pruning is thoroughly understood and carried out. The question of

VARIETY is important to the growers. In the first place the earliest green fruit realises the highest price, and therefore the sorts producing the first saleable berries are largely sought after. Crown Bob is one of the most popular varieties and is largely grown, as the fruits are suitable for gathering either green or in a ripe state. Lancashire Lad is another kind that is largely grown, and Whinham's Industry appears to be increasing in popularity, though I have heard complaints from growers that its dull appearance when ripe is a drawback when competing with others in the market. The other day I saw a plantation of Greengage Gooseberries, a fine large variety of dwarf, sturdy habit that might be grown in private gardens with advantage. In the district I refer to a popular variety is one raised locally and called Couzin's Seedling. The fruit is large and yellow, and the bushes are strong growers and crop freely. The variety is a good one for market, and, so far as I know, it is grown but little outside the neighbourhood where it was raised. If widely dis-

tributed, I feel sure this variety would be largely grown, but the raiser guarded it so jealously, that up to the time of his death, so I was informed, it was not grown outside his own plantation. Other sorts are to be seen, but generally the list is limited.

Taken as a whole, Kentish Gooseberry growers are a shrewd class of men, ready to take advantage of anything that will tend to their benefit. They have, doubtless, room for the complaints they make, particularly on matters of distribution and where railway rates are concerned. Their knowledge of horticulture does not extend far beyond the limits of the fruit plantation, but here there is much that is interesting and instructive in studying the commercial side of Gooseberry culture.

G. H. H.

KITCHEN GARDEN.

SALADS IN SUMMER.

THERE has seldom been a more favourable summer so far for salads, the cool, moist weather being all in favour of Lettuces and Radishes, the two most indispensable of all salad plants. In many gardens there is a difficulty in finding positions cool and moist enough for these, yet in good tilth, for it is useless planting or sowing in lumpy, badly cultivated soil. Frequent sowings of Lettuces are imperative if a succession is to be kept up, and a good plan is to sow where they are to remain, thinning out the plants when large enough to transplant, and making a few separate rows of the thinnings. The check given to these by lifting and replanting is slight, but it is sufficient to make them a little later than those left in the rows, and they make a useful succession. Sowing about once in three weeks will secure a regular and constant supply all through the summer. The earliest sowings will, of course, be made under glass, and the plants put out on a warm border. Where Celery trenches are got out early the ridges between these are the best positions for the second early crop, and I am now taking splendid heads of Sutton's Favourite Cabbage Lettuce from these. This is one of the best of summer varieties and unequalled for crispness and fine flavour, standing a long time before running, and early in the season it comes in before any other I have tried, being fit for use in so small a state.

A good succession to the earliest crops of this variety will be found in the brown-seeded Cos, plants that have stood the winter on a warm border. Rows of Lettuce do capitally between Peas, the ground being usually in good condition for the latter, while the partial shade provided suits the Lettuce well. Any of the fine white Cos varieties that are now to be had under so many different names are good for such a position, sowing at the same time as the Peas between every other row, and filling the intervening ones, after the Peas are staked, with plants drawn from the seed rows. Both crops come off together, or at least soon after each other, when the ground, without any other preparation than hoeing, is ready for the latest winter Greens or spring Cabbage.

Radishes may be very similarly treated in spring, but, not being so long in the ground, are often sown between other crops, as early Carrots, dwarf Peas of the Chelsea Gem class, and others. It is true that no amount of care in a hot summer will give us the fine succulent roots that we have had so far during the present year, but on good soil, with a little manure sown in the drills to give the young plants a

start, a fair sample may be grown all through the summer. Chives, Mustard and Cress, and other of the smaller salads may be kept going with very little trouble in most seasons, and a favourite addition to the salad bowl in many places is a few leaves of Tarragon.

Tomato Dessert.—The bright red fruits of this little Tomato are very attractive, and although of course the weight per plant would fall far below that from plants of the larger kinds, it is very free. They are liked in the raw state, and in any case they would improve the look of the dessert early in the season, even if the fruit was not cared for. They appear on long bunches in a two-ranked manner, not a spreading bunch as is usual, and a bunch taken off the full length and laid on Vine leaves looks very pretty. The flavour is singularly sweet and pleasant, many people who do not care for ordinary varieties eating this. The plant is of good habit, the fruit setting freely and coming quickly to perfection. It is met with under a great many names.—H.

Cauliflower First Crop.—At p. 490 "A. D." writes of the value of early Cauliflowers. Many of the earliest kinds are selections from the popular Snowball, but that does not make a good selection unpopular, as if a kind that gives a little more size of head without loss of earliness can be obtained it is a distinct gain. First Crop, though not much larger than Snowball, is an ideal Cauliflower for sowing under glass at the end of January or early in February. Like Snowball, it may be had fit for table in a little more than three months if sown thinly and given attention. For forcing I find First Crop invaluable, as its leaves are small and the flower is firm, and though not large, quite big enough. From plants sown in a cold frame early in March and planted out on a warm border I am now cutting (June 18) small compact heads. These are grown between rows of 3-foot Peas.—S. M.

Summer Cabbages, Main Crop and Matchless.—For some years a great deal of attention has been paid to early Cabbages, and rightly so; but in a backward season, such as we are now experiencing, a good breadth of Cabbage to come in during June and July is welcome. No one can grumble at the quality of Ellam's, but I do not advise it for use at the season named. Main Crop and Matchless are excellent varieties to follow Ellam's. They are not too large and remain a long time fit for use. Another good point is that Matchless sown in the autumn is little inferior to Ellam's as regards coming in. Main Crop is cone shaped and of equally good quality as Matchless. Some growers may not require summer Cabbages. I do not advise them unless they are young and clean, but where a large quantity of vegetables is needed they are serviceable. Many put out small plants of the autumn sowing for a summer supply, but I prefer to sow the varieties named at the end of February or early in March.—G. WYTHES.

The Onion crop.—"H. R." (p. 490) says the present season has been a favourable one for sowing, as germination was rapid and sure. "H. R." I think, must have had more favourable weather than we have, as I never remember a season when the Onion seed was so long in germinating and the plants so weakly at the start. So badly did my plants look when pushing through the soil, that I again sowed a few rows, thinking it wise to do so. I only need medium-sized bulbs and do not sow under glass, but the ground is well done—indeed, it was the Celery quarter and the soil is light. The plants during the past week or two have made good progress, but they are fully a month later than last year owing to the delay at the start. There was no lack of seedlings, but they were very weak. I have heard numerous complaints of slow germination this season, and it may be owing to the seed not being so well matured and the cold, unless weather we experienced when the seed was starting. The plants from seed sown six weeks after

the usual time are now as large as those sown early. Winter Onions planted out early made very slow progress, and some plants raised under glass, that I saw early in May, when set out looked very sickly.—WEST MIDDLESEX.

An early Potato—Ninety-fold.—Needing early Potatoes as soon as possible, I have for years planted the earliest kinds. Of course there is some risk in early planting, some varieties being much hardier and more robust than others. This season the new Ninety-fold is my best and earliest kind. The season is later than usual. I have in previous years lifted earlier than the first week in June in light soil on a warm border, but I fear many will not lift nearly so early this year. Ringleader follows closely, but is not so prolific. The new kind has a much stronger growth, with erect, strong haulm. I was much pleased with Ninety-fold last year, and planted a much larger quantity this year early in March. The crop I am lifting has only been three months in the soil. This is good work for such an inclement spring, as I notice less robust kinds are very late. Ninety-fold is a white-fleshed, kidney-shaped tuber, and certainly the heaviest early kidney I have grown. Not only does it crop well, but boils dry and mealy, the flavour being excellent, and this in a season we could scarcely expect such good quality.—G. WYTHES.

Large Spinach.—Mr. E. Beckett sent to the recent meeting of the fruit committee leaves of a Spinach called The Carter that measured 15 inches from base to point, and were 15 inches broad at the base. But whilst admitting that such leafage as is referred to exhibits good culture, one is tempted to ask, who wants it? Is it probable that such leaves would be at all so pleasant for food as others not one half the size and which have been much more quickly produced? But the variety does not under ordinary garden culture produce such coarse leafage. I showed in THE GARDEN some time since that this particular Spinach was the well-known Longstander under another name, and although the committee at the Drill Hall asked that the variety be grown at Chiswick with the Longstander and the Viroflay, yet the result is a foregone conclusion. I have often observed when visiting gardens that, in spite of all that has been written about the excellence of the two varieties named—Viroflay, or Victoria, and the Longstander—gardeners continue to adhere to the Old Flanders, still thinking that the round seeded and the prickly seeded are diverse because sold as summer and winter Spinaches. If growers of Spinach will but try either of the newer ones, and especially the Longstander, thinning the plants well in the drills, they will not care to revert to the Old Flanders variety.—A. D.

Early vegetables on open borders.—This cannot be considered an early season, although some three or four months ago it promised to be extremely so. This season I gathered the first dish of Peas (Chelsea Gem) on June 8. These are grown every year at the foot of a south wall and above Apricot tree roots, and nothing can be more satisfactory. These were sown the first week in January. Sharpe's Victor Potato gave good tubers on June 1. These were grown at the foot of a low wall facing south. It is astonishing how the warmth from the wall helps to swell the tubers. Such situations are most useful, as they can be readily covered at night in the event of frost. The first Cauliflower was from plants wintered in pots in cold frames, and planted out on a warm border. These were ready the first week in June, shaking hands with late Broccoli. Early Erfurt is the Cauliflower I grow. Turnips were ready on May 28. These were from a warm border, the kind being Extra Early Milan. The large amount of rain during May just suited these. I cannot find any Carrot to equal a good stock of Parisian Foreing for earliness. This, sown early, comes into use in June, and, although small, the roots are tender when eaten in a small state. In Cabbage Lettuces I find All the Year Round as early as any. Hicks's claims the first place for early Cos kinds. I obtain the first supply by

planting these and the true Bath Cos at the foot of vinery walls. These suffer considerably through the winter from slugs, but not so much as in the open. It was astonishing the difference in the time of Cabbage coming into use compared with last year. My method is to plant in Onion ground, doing this first from plants raised from seed sown at the end of July, and again about August 9. I plant only the small-growing kinds. Good heads can be had early in April.—DORSET.

CABBAGE SPROUTS.

I do not think that anything I have written on this matter can be construed to mean what Mr. Wythes implies in his opening sentence (p. 509), viz., that I held the sprouts of Cabbages to be of better quality than the original heart, and certainly in the note (p. 411) which he criticises I make no allusion whatever to quality, though I have in former notes held, and hold still, that given good culture the quality is equal. I think nothing of the plea as to tidiness, and see nothing untidy in a well-kept Cabbage bed bristling with good sprouts. My bed now is as free from weeds and old leaves as any spring-planted bed could be; certainly the growth is more irregular, but regularity cannot exist in any bed after cutting commences, and I see no reason why it should exist, as I do not wish to import the principles of carpet bedding into the kitchen garden. Except through stress of circumstances, such as loss of crop through winter frost or through belting, I see no reason for sowing such a hardy vegetable as the Cabbage in heat at a time of year when the glass department in most gardens is in a congested state, and I manage very well to keep up a succession without it. Of course, keeping the old stumps about for a couple of years is out of the question in any well-managed garden, and I disclaim any sympathy with the practice, but it is a badly-treated Cabbage bed that will not stand a season's growth without exhaustion and yield profitably all the time. I should like to echo Mr. Wythes's pertinent query as to the need for so many varieties to provide a succession. I see no such need. With many so-called new varieties of Cabbages and other things there is a distinction without a difference. If quality and suitability increased in the ratio claimed by the distributors, we should now be eating Cabbages of the quality of the best Asparagus, and what our Peas would be like is beyond conception.—J. C. TALLACK.

— Mr. Tallack's case is so strong in favour of these that he needs no support from me or anyone else in favour of this practice of leaving Cabbages to yield one, two, or more crops in succession, after the cutting of the first heads. Few modern practices have been more justified through long years of experience and profitable results. In fact, Mr. Wythes hardly questions either the quantity or quality of Cabbages produced on the sprouting system, and confesses that he has never tried it. This very material fact, however, does not prevent Mr. Wythes from condemning this sensible mode of further utilising the Cabbage. No one, so far as I am aware, has found fault with Mr. Wythes or any other grower who prefers converting the Cabbage into a short-lived, once-cut annual. If that system suits and pays them best, doubtless they will follow it, but it is manifestly unfair to accuse those who would increase the produce of individual Cabbages with untidy or slovenly modes of culture. Mr. Wythes brings two more direct charges against the sprouting of Cabbages: the system favours the growth of weeds and the exhaustion of the soil. After a practical experience of over forty years of this mode of growing Cabbages, I emphatically deny the first charge. It must be a strong weed indeed that can hold its own amid a break of sprouting Cabbages; the Cabbages, by mere force of numbers and vital energy, choke out weeds. And then as to soil exhaustion. This is easily neutralised or prevented through an occasional soaking with house or stable sewage, soap-

suds, house slops, or dressings of other liquid or solid manures. The dense shadow of the Cabbage sprouts also protects the soil from losing food through sunshine, air, wind, &c., while the deep-running roots are not bad cultivators. No practical difficulty has ever been found in obtaining, under liberal culture, first-rate crops in succession from land that had been under Cabbages and sprouts for from twelve to eighteen months. Mr. Wythes' chief fault with the sprouting system is that it produces a plethora of sprouts, and not that the sprouts are neither good eating nor profitable for sale.—D. T. F.

— I consider there are times when Cabbage sprouts are very useful. When planting in autumn I always put out three or four kinds, and arrange them so that there are a few rows of a large, late-heating type on the side of the patch where I can leave them advantageously. These follow Ellam's and give heads after the former are over. These are left to give sprouts. All the quick-heating kinds are cut, the stumps pulled up, and the land roughly dug and broken down. This year I am using it for Carrots. I removed two or three rows of these quick-heating kinds and planted two rows of early Potatoes early in May, and am hoping to get them off in time to plant small-growing Cabbage again at the end of the summer as a trial. I consider stumps standing long on the ground very exhausting to the land. I doubt, as regards quality, if heads in November were cut from these giving a second crop and from plants that had been planted at the end of the summer and cooked, anyone could tell the difference. I must admit, as far as tidiness is concerned, old stumps are to be condemned. It is astonishing what a large quantity of nice young heads and in a very short time one can get in the autumn when the plants are put out a foot apart each way. Will Mr. Wythes tell us if he plants the same kinds in October, November, and February, and if so, what is the difference in the time of their coming in? I plant at twice, September and end of October, using four kinds, and by so doing I can keep cutting over a long period.—DORSET.

Potato Famous.—Last year I grew a few rows of a medium-sized kidney under the above name, and was so pleased with the results that I resolved to give it a further trial. Twenty rows were accordingly planted on a south-west border on March 3 last. On the same date and on the same border Sharpe's Victor, Myatt's Prolific, and several other well-known sorts were also planted, and a trial lifting took place on June 18, when it was found that Famous had quite out-distanced all others in point of earliness. The tubers were large and ready for use, while Sharpe's Victor will require another fortnight before the tubers will be fit, and the others a still longer time. In point of yield Famous is, perhaps, not quite equal to Sharpe's Victor, but, according to results, it surpasses it in earliness. It is a white kidney, and the quality when cooked is excellent. I shall reserve a good stock of seed tubers of it for another season's trial, when it will be interesting to see whether it will again prove as satisfactory as it has done this year.—A. W.

Seakale.—Growth in Seakale is very backward indeed for the time of year, and at the time of writing is now only ready for the thinning out of the young shoots. Where crowns are required early for forcing this tardiness of growth will prove a serious obstacle, for they will not be ready in time, unless measures are taken to forward growth as quickly as possible. To do this, liquid and artificial manures can be relied on, and the surface of the soil should also be kept well stirred so long as it can be done without damaging the leaves. Quick-acting and soluble manures, such as salt, muriate, and sulphate of potash, also nitrate of soda, are best applied before rain falls, or while it is actually falling. If applied during dry weather, the precaution should always be taken to well mix the chemicals with the soil by hoeing it to a fair depth, when little or no

waste will occur. Liquid can, of course, be applied at any time when it can be spared, and where this and the labour for applying it are plentiful artificial manures are unnecessary. Permanent plantations which yield the latest supplies of Kale are also better for a little help in the way of food, and, like the above, they may have this so soon as the thinning of the young growths has been done.—S. E. P.

Lettuce Commodore Nutt.—Usually this little Lettuce is grown only for early spring use in pits or frames, but for private use I claim it is as good if not better than some of the larger-growing kinds. In gardens of limited extent, where a long supply is needed from a small space, this variety should be chosen, at any rate, for the early summer supply outdoors. At the present time I have it in quantity with hearts as full and solid as possible; indeed, although appearing small, there is more material in it than is found in some of the larger growers. It has stood the spell of dry, hot weather uncommonly well and is slow to run to seed. Early Paris Market sown at the same time, and which has been furnishing fine heads of a beautiful colour, is running to seed almost to a plant, showing that it cannot endure summer drought so well as Commodore Nutt. All Lettuces delight in good soil, and the smaller ones in particular need this—at any rate, in summer, or their diminutive size is still further decreased and the quality deficient.—WILTS.

Cabbage Lettuce All the Year Round.—This is an excellent companion to Hicks' Hardy Cos, as, like that variety, it is very hardy, and always stands well outdoors through the winter. I grow the same number of this sort as of Hicks' Cos under the shelter of walls for early work and am never disappointed with it. I tried Grand Admiral one season, but it was not nearly so satisfactory, and have discarded it in consequence. All the Year Round is also first-rate for wintering in cold pits. For this purpose the best way I find to deal with it is to have the plants in three stages of growth. At lifting time the first lot should be fit for use, the next lot three-parts grown, and the remainder about one-third of their natural size. There is then no difficulty in keeping up a good supply through the winter and early spring months and until those under the walls outdoors are ready for use. The same kind is also principally relied on to afford a regular succession of firm hearts during the summer months.—A. W.

EARLY BROCCOLI.

The early Broccoli crop is more easily managed than a later one, as if the heads form in the autumn a large portion of the crop may be lifted and stored. To get good results, planting should not be longer delayed. Of late years some excellent additions have been made to the early varieties. One of the best is, doubtless, Veitch's Self-Protecting, a variety too well known to need describing. It is not advisable to place all the crop on one quarter, as by giving different positions a longer succession is secured, and in warm localities, in light soil, a south border is too sheltered for the main crop. Of this variety I plant a small portion in the position named, but the bulk of the plants in an open quarter, as the growth is hardier. Another excellent variety is Sutton's Michaelmas White. This follows the Protecting. Walcheren is also a good type for autumn use. Any of the above-named are reliable for use from September to December. Many do not grow the early Broccoli as much as the late Cauliflowers. I prefer the Self-Protecting Broccoli, as it is milder in flavour than the Cauliflower and with care may be had well into December. I wish that the Self-Protecting varieties were more hardy, as a few degrees of frost soon injure them.

Walcheren is also similar to the Cauliflower as regards hardness, and, though I include it in my list, it is not so reliable as the Protecting, the heads not being so well covered with foliage. On

the other hand, it is earlier than the one named and valuable as a succession to summer Cauliflowers. Last season I had some half dozen varieties of early Broccoli on trial. One I grew in 1896 was so excellent that I gave it more space last year. This was Sutton's Superb Early White. In many respects it is not unlike the old Snow's Winter White. Superb Early White is not a large Broccoli, but it has a beautiful head, perfect in shape, snowy white, and, what is so valuable, it is hardier than many I have grown. In 1896 it stood the frost uninjured. This is in a measure owing to its dwarf, sturdy habit and abundance of thick leafage which covers the flower. This variety, sown in April, was ready early in January, and the heads, if lifted and stored in a shed or cellar, remain good for weeks. Another stock of great merit was Sandringham. This is a re-selected Snow's Winter White, and if the stock keeps as good as it was last year it will be a gain to growers, as it turned in freely during January, at a time the Broccoli is valuable. Christmas White promises to be a popular variety to follow the earliest kinds. The plant is a dwarf grower, with medium-sized leaves protecting the head. It should be planted at the end of June or early in July for cutting at the season named, as I find, like Snow's, it must be given a fair season's growth. G. WYTHES.

Potato Snowdrop.—Good late-keeping Potatoes are always valuable, and any kind that can be had good from digging time up till new ones come in from the open ground deserves extensive cultivation. These remarks apply forcibly to Snowdrop. I had not given it a trial till two years ago, when I saw it at Downham Market. I was then pleased with it and resolved to try it. Last year I planted a good breadth of this kind on a piece of land I worked by the plough and dressed with the refuse from the pleasure grounds. It produced a fine even crop of tubers of the very best size for the table, the quality also good and the flesh white and mealy. I have used this Potato from October till the present time (June 9) and can see no difference since I commenced using it. With me Snowdrop is not a strong grower and was not badly diseased.—DORSET.

Early spring Broccoli.—In planting the mid-winter supply it will be well to allow as long a season of growth as possible. I have found it advisable to select strong plants, giving an open quarter and ample room. A few years ago, when it was possible to obtain a true stock, there was no variety to equal Snow's Winter White. For two or three years I have relied upon Penzance Early White and Superb Early White. These are the two best early spring Broccoli I have grown, but they should be planted as early in July as possible and be well attended to in hot, dry weather in the way of moisture. As a succession to those named to come in during March it is well to plant Veitch's Spring White or Main-crop; these in favourable seasons are ready early in March. The latter is a remarkably hardy Broccoli; though termed a main crop variety, it is really an excellent late winter sort.—S. M.

Potatoes.—I have rarely known the early Potatoes so late as they are this season. In many cases it will be necessary to consider, now July is in, whether the earliest Potatoes must not make way for green crops. In some few cases the Potatoes are ready to lift, but in many, growth this year is much later, and to lift for storing is not advisable, as unless the skins are set they will not keep. I am following a middle course wherever possible. I allow a fair width between the rows, and, in the case of small-topped varieties, plant a green crop between the rows. By using a little care in lifting the Potatoes, the plants are not injured. In some cases the haulm of the Potatoes may need placing in position before planting. I have at times shortened it if the variety was full grown. This season my earliest Potato is Ninety-fold, and excellent it is in every way. It is a good plan to go over late quarters and remove rogues; they can now be seen at a glance, and

if left the stock becomes much mixed and less reliable.—S. M.

Cauliflower Early Forcing.—Nice heads of this, somewhat larger than a large breakfast cup, were available in the week ending June 11, and this from seed sown the first week in February. Autumn-sown plants kept all through the winter would not be much before this. I have never been able to do this Cauliflower well, except by potting up the seedlings and planting with a good ball from the pots. Pricked out and transferred from the open ground, the plants club, and that despite every precautionary measure, the only means of carrying the crop fairly well through being a heavy soaking of water, and earthing well up, that the roots emitted above the club may carry the heads through. This, however, is not advisable if potting up can be practised, as with plants partially saved from the club there are a hardening of the stem and a deterioration of the head both in size and quality.—E. B. C.

Late Broccoli.—Scarcely have we done cutting the last of the so-called spring Broccoli, my latest this year being the excellent June Monarch, than we have to consider next season's crop. I find, unless the plants have a long season to make their growth, they are not always reliable. Most years I have been able to plant the late Broccoli on land cleared of Strawberries, and being short of space I shall be obliged to do the same this year. Owing to the later Strawberry season I am unable to clear the crop so early as desired; so to avoid starving the plants in the seed-beds they are being transplanted to rows 12 inches apart in the row with 6 inches between the plants. They will lift well with a trowel later on and soon make up for lost time. I grow the Strawberries as annuals mostly, and the land is in good condition for the Broccoli, as it only needs surface cleansing. I have found no varieties of late Broccoli to equal Model and Late Queen for April and May supplies. These two are reliable, very hardy, and the cream of the late kinds. June Monarch is invaluable as a succession. This follows the two named, and there is no difficulty in keeping up the supply till Cauliflowers come in.—S. M.

Early Peas.—Of early dwarf Peas, St. Osyth Gem, Chelsea Gem, and William Hurst, sown on a south border in November, there was nothing in point of earliness between the two latter, both being ready at the same time. Chelsea Gem is a trifle stronger, but the two are so nearly alike that it is hardly necessary to grow both. St. Osyth Gem has a stronger haulm, is slightly taller, and rather later. It is larger alike in pod and pea. In this matter of a successor as a dwarf Pea to the first earlies it is doubtful if anything is better than Daisy, to combine that is the characteristics of a capital cropper with first-rate quality. In connection with Potatoes it has been remarked that if only one variety were grown it might well be Windsor Castle, and so if a grower were restricted to one Pea he might do worse than rely on Daisy. In the open quarter the first sowing is two rows respectively of Veitch's Selected Early, William the First, and Criterion; they follow each other well in the order named.—E. B. C.

Autumn-sown Onions running to seed.—It is curious to note how few have complained of their Cabbage going to seed, but it is strange that so many Onions should run to seed. I always sow at the end of August on deeply-worked ground, and being a very mild winter I had no losses among the Onion crop early in spring. When thinning them out those that were not wanted were taken up carefully and planted out. When they commenced to grow I saw that a good portion of them was going to seed. Of the White Spanish, Newnham Park, and a selection of my own at least half has gone to seed, nor can I see the least difference in those that were planted out. A very large percentage of the Tripoli section has gone to seed. It is clear it must be owing to the season, seeing that the treatment is the same as in former years. No

doubt the mild winter is the cause of the Onions running to seed so badly this year.—DORSET.

Vegetables at Richmond.—This is the earliest of the summer exhibitions at which vegetables are largely shown, and, certainly for the season, a first-class beginning was made. If later shows see a material advance in finish and quality the product will be fine indeed. Peas were splendid samples. Of these in the numerous exhibits, Duke of Albany and Early Morn were capital. I should like to see in Peas more individuality. The finest pods, and markedly distinct, were not named. Potatoes also were generally good. Very handsome were Supreme, Satisfaction, Ashtop Fluke, First Crop, and a rather too large, long, flattish seedling. The finest Tomatoes were Perfection, generally so shown, Duke of York, Eclipse, and Excelsior. In these fruits there is so little individuality that one variety may have a score of diverse names. Still, some of the dishes were exceptionally good and rich in colour. The chief Carrots were the Early French Horn, called here Early Gem and Early Forcing, and the Nantes or Summer Favourite. These were small, as Carrots generally are shown, yet very tempting samples. Canadian Wonder and Magnum Bonum were the best, and excellent dwarf French Beans. Mammoth Longpod, Leviathan, and Seville were the names given to Longpod Beans, generally long, clean, and handsome; Model and Improved Telegraph, the best Cucumbers in the collections; and Magnum Bonum, Walcheren, First Crop, Defiance, and Mont Blanc the Cauliflowers. Certainly in these the only distinctions are found in the names. The heads as shown, very white, solid, and of nice table size, were all like one another. There were also white Lishon Onions, giant Lettuces, Asparagus, and Turnips. All these things show that even with a late season and very little sunshine, yet even so early as mid-summer superb vegetables can be exhibited.—A. D.

NOTES AND QUESTIONS.—KITCHEN.

Peas.—How wonderfully well Peas look everywhere this year. My own trials in three diverse parts of the county of Surrey are excellent. They could not well look better, and in fields where grown for market the breadths are very vigorous and clean. It is true, Peas are very late in podding this season, but there should be a wonderful supply in the market presently.—D.

Too many Broccoli.—I note "G. W." (p. 310) speaks very highly of Monarch. Will he kindly say if this is later than Latest of All and Methven's June? I see that a correspondent in a contemporary points out that there was a sameness in a goodly number of so-called kinds at the Temple show. I can see little difference in the kinds of to-day as regards lateness compared with kinds I could name that were grown thirty years ago.—DORSET.

Late Queen Broccoli.—This is a very useful variety, especially where there is little convenience for keeping autumn-sown Cauliflowers through the winter. The plants are dwarf and the curd is well protected by the ample foliage until fit to cut. In the open quarters I cut the first heads in the last week in May, and there will be a succession for three weeks at least, and this at a time when green crops are not too plentiful or good in quality.—H. R.

Big Radishes.—I am glad to see "Cornubian" making a protest against these (p. 510). I do not object to large specimens of anything, provided the quality is first-rate; but I yet have to learn that big Radishes are good. I am aware one often sees them large on the market, but this does not prove they are then at their best. In big towns many purchasers know nothing of the standard of quality, size being the first consideration. Recently I went into a shop and saw some of these big Radishes, and on tasting one I found it so hot and strong that there was no comparison between it and roots of French Breakfast, young and tender, growing in my own garden.—J. CROOK.

ORCHIDS.

LÆLIA PURPURATA.

THE subject of the accompanying illustration is a piece of a plant bought at the sale rooms in the early sixties by my father, from whom I received a small piece as a memento in 1871, having had it under my charge at home. This piece I again divided a few years afterwards, and brought a small portion only with one lead to Gunnersbury in 1876. Since that time I have grown it on until the present specimen has been obtained. During the past three seasons it has produced in the aggregate nearly 100 flowers. The plant is grown in an ordinary stove temperature, where I grow also *Vanda*

is well known in the trade treats his *Dendrobies* in a similar manner; these I noted as having been shaken out of their pots and soil, then laid on their sides under the benches filled with other kinds. This variety was *Dendrobium Phalenopsis Schroderianum*, a nearly or quite deciduous one, it is true.

During the many years I have grown the plant in question I have never rested or eased it by not allowing it to flower, as some do their Orchids. Every year it brings to perfection its crop of bloom, whatever it may be. I am disposed to think we may, and do at times make mistakes in attempting to follow too closely the conditions which obtain in the native habitats of certain Orchids. We have not the surroundings, nor can we always imi-

tate them in the pot, as I fail to see the gain in mounding it up too much.

This *Lælia* was bought under the name of *L. purpurata superbiens*; it has flushed sepals and petals, being identical with what is now known as *L. p. Williamsi*. My reason for showing it was to illustrate the opposite theory to that under discussion anent the degeneration of Orchids. I might add that it is shaded during all bright sunshine, the same blind covering the stove *Dracenas* and *Caladiums*.

JAS. HUDSON.

***Thunia Bensoniæ*.**—A good form of this species is very showy at this time of year and a nice contrast to such as *T. Marshalliana* and other white-flowered kinds. The stems when strong

Lælia purpurata at Gunnersbury House. From a photograph by Mr. Gregory, Croydon.

tricolor, &c., with *Crotons*, *Dracenas*, *Caladiums*, and small *Palms* as decorative plants. I mention this to show the temperature to which it is subjected the season round. It is never now removed to another house, which it is well to note. I did so on one or two occasions when in flower, but the bulbs shrivelled during the interval too much to please me. After one such case I decided to pull it to pieces and re-make it up completely, washing the roots and leaving it after the manner of an imported plant, only somewhat fresher of course. I shall not hesitate to do so again if need be, as I am disposed to think this is a good way to treat some Orchids when not so satisfactory as one could wish. Another grower who

tute them as we would like. For instance, during what we term the resting period we can easily keep Orchids too dry, and they suffer in consequence. They may possibly be quite as dry in their native habitats, but with a far heavier fall of dew at night, which we cannot so easily imitate; hence they should not be kept so dry at the roots when under cultivation. With me this *Lælia* flowers, as a rule, every year during the second or third week in June, yet possibly the temperature for the year would average more than that to which this variety is subjected when grown in the *Cattleya* house. I do not depart from the usual treatment as regards soil, which consists of peat, charcoal, and *Sphagnum Moss*, but possibly I keep it

are 2 feet high, and the flowers occur similarly to those of *T. alba*. The colour throughout is a rosy magenta, this becoming much deeper on the front of the lip, and the crests are yellow. Like the others, it must be grown quite unshaded and well ripened after flowering, the roots being kept quite dry in winter.

***Oncidium dasystyle*.**—Though small, this is a singularly pretty plant, flowering at various times in the year. Not many flowers are produced upon a spike, and these have yellowish sepals and petals, the lip having a blackish purple or crimson crest, giving it quite a distinct appearance. I have seen it doing well under various modes of culture, but the healthiest, most free flowering plants are usually those grown well up to the light in an intermediate or cool house, the

compost being kept very thin. It is a native of the Organ Mountains, in Brazil, and was introduced by the late Mr. B. S. Williams in 1872.

Cattleya Aelandiæ.—This I have noted in good order this week, a nice plant on a large square raft carrying many flowers. The plant needs care, but is more satisfactory treated to a little compost than when grown on a bare block. At the same time it is easy to give too much, and this causes the roots to become unhealthy, and the vigour of the plant is reduced. A great advantage in using rafts is the fact that nearly all the old compost may be removed and new substituted without disturbing the plant—an important point when dealing with this somewhat erratic species. It is best grown in a good light in the Cattleya house.—H.

THE ATMOSPHERE OF ORCHID HOUSES.

THE keeping up of a correct and well-balanced atmosphere in Orchid houses is an important detail in their management and one frequently neglected. So sensitive are many of the plants, that, no matter how well they are treated in other ways, they will not long continue in a satisfactory condition unless a proper atmosphere is maintained about them. It is the one thing that in cases of difficult subjects is wanting in our houses, for unquestionably we can treat these difficult subjects to better conditions as to a rooting medium than they obtain in a state of Nature. But to provide a suitable atmosphere where air, moisture and some subtle element that obtains in the open air of their native habitats are always properly blended is impossible in the limited capacity of a glass-house. In consequence, some species which are naturally of a vigorous constitution go on and improve under cultivation, while the more sensitive gradually become weak. Some of these are probably only short-lived in the natural state, but this does not hold good with others of which plants are imported that in the ordinary course of events must have taken many years to develop. As a means of overcoming this difficulty we are occasionally treated to long disquisitions as to the conditions that obtain in their native habitat. Such a plant is found growing fully exposed to the sun, another in the depths of a thick forest where the sun cannot possibly reach it, and by following a course of treatment apparently agreeing with this, beginners in their culture have been led to forget that circumstances alter cases, and that what is perfectly right and proper to a wild plant is quite out of place when that plant is taken away from all natural influences and cooped up under a glass roof. This is quite wrong, and, helpful as all such information is to form an opinion as to what will suit a certain plant, to follow it literally must lead to disaster.

The proper atmosphere of an Orchid house, as we know it, is one in which the air is continually changing, kept to a correct temperature according to the state of growth of the plants, and duly charged with moisture and ammonia in some form. This is good as far as it goes, and the best we can do, but to follow the plants through their resting and growing seasons, to supply on the one hand sufficient moisture for the plants' need, on the other to avoid extremes which may lead to a soft and flowerless growth, requires far more care and thought than the average gardener or Orchid grower can bestow. The number of plants of different habits and likings which are grown in one house increases the difficulty. Here is where many beginners go wrong. They expect—in the gardening

papers, for instance—to find laid down the exact mode of treatment: this is evident by the nature of queries that are often to hand respecting their culture. It would be easy enough to say that a house must be damped at such a time and air be admitted at another, but such a way of teaching would never make anyone sure of his ground any more than it would suit the plants, and, useful as it undoubtedly is, personal experience in and about the houses, reading the lessons that only the plants themselves can teach thoroughly, is the surest of all roads to success. It would not, perhaps, be correct to say that what is pleasant to the senses is right for the plants, but at the same time it is easy to tell, on entering a house, whether it has that buoyant feeling that is necessary, or whether it is reeking with too abundant moisture on the one hand, or dry and draughty from too much air and fire-heat on the other. Fire-heat must be tempered by moisture, and the air currents must be in accordance with the outside conditions. With a cold wind blowing it would be folly to put on as much air as on a soft, mild day, and even if the sun is bright on such occasions, the balance is more easily kept right by closer shading and free damping. Heavy damping, again, on dull wet days is wrong, so obviously wrong, in fact, that few will fall into this mistake.

As to providing the ammonia, there are several ways of doing it, such as by placing sulphate of ammonia on the pipes, damping with soot-water or liquid manure. A little dry soot and lime sprinkled about out of sight under the stage, too, has an excellent effect on the atmosphere, and is very distasteful to slugs and small snails as well. It will be noticed that all these aids to a correct atmosphere are more lasting in their effects in a house of fair capacity than in a small, narrow one, where the first upward move of the ventilators takes out the greater part of the moisture from the atmosphere. So that here again discretion must be used, a small structure needing more replenishing of the atmosphere in comparison with its size than a larger one.

These are the most salient points to be noted, and others unavoidably left out will occur to the grower as his experience widens, and he finds by this experience what an important point a proper atmosphere is. H. R.

Cattleya Leopoldi.—The earlier spikes of this distinct Cattleya have been very fine, a nice spike with eighteen large flowers being especially good. This is from a plant imported about two years ago. The individual blossoms are nearly 4 inches across, the sepals and petals coppery green, with deep purple spots, principally about the apex and margin, the lip bright purple. The plant is a strong and vigorous grower and of easy culture, growing from the base in spring and rapidly forming a large stem-like pseudo-bulb. After the flowers are over and the bulb has fully developed, keep the plant quite dormant, but allow sufficient moisture to prevent the least shrivelling. It is a native of Brazil, and was introduced about 1850.

Dendrobium moschatum.—This is a fine old species, but its flowers, unfortunately, last but a short time in good order. Still, while they are fresh the bright yellow of the sepals and the rich maroon blotch on the lip make a fine contrast, and a large well-flowered specimen is very imposing. The stems grow 6 feet or 8 feet high, are leafy over the entire length at first, and go on several years producing these fine racemes of flower. They are, moreover, produced in a longer succession the same year than those of most Dendrobiums, especially the evergreen kinds, for as often as not all the racemes on such as *D. densiflorum* have the flowers open at once, while on

D. moschatum there are often many in bud at the time others are fully open. Naturally the plant requires a good deal of room, but beyond this it is of the easiest possible culture, and will grow equally well in the Orchid house proper or any warm plant or fruit house. Its roots freely and likes large rough lumps of peat and charcoal, and consequently a large pot. Water must be freely applied as long as the growth is active, but in spring, when the young shoots push from the base of the old stems, too heavy watering is inadvisable. It is a native of Burmah, and was introduced about 1825.

Ornithocephalus grandiflorus.—This is the only species of the genus that has become at all popular and is a pretty plant when well grown. The pseudo-bulbs are hardly perceptible at the base of the sheathing deep green leaves, and the spikes appear to spring from the base of the leaves, similarly to those of *Miltonia vexillaria*. The pseudo-bulb is there none the less, only small, and from it the spikes proceed, each about 9 inches or 10 inches in length, arching and many-flowered. The sepals and petals are white, with a greenish blotch, the bent column—from which the genus takes its name—being in this species pure white. A native of various parts of South America, it must be kept fairly warm and likes plenty of sunlight. I saw some fine plants of it in flower recently growing in company with other Orchids on flat blocks of wood and only very little compost, these being hung up at the end of a house largely devoted to *Laelias* of the aneeps and similar types, and consequently only lightly shaded. As the spikes of flower are forming often in the winter months, the roots should never be much dried, and during the summer the small amount of compost renders very close attention necessary, as it is a thirsty subject. Though discovered by Gardner as far back as 1837, it is only during recent years it has been at all well known in cultivation.—H.

HOULETIA BROCKLEHURSTIANA.

THERE are many good and showy garden Orchids that are by no means well known or popular, and although this plant is frequently met with, it cannot be said to receive so much attention as it deserves. It is the type species of the genus and the finest of them all, the erect, many-flowered racemes of reddish and yellow blossoms being very distinct from everything else. The pseudo-bulbs are egg-shaped, about 3 inches high, and from these the flower-spikes proceed. The roots are rather sensitive to disturbance, consequently when giving a shift it is well to allow plenty of room, and use a lasting yet rough and open compost. I have seen good results follow the use of loam in addition to the usual peat and Moss mixture, but I would not advise it for weak, badly-rooted, or unhealthy plants. Like so many other Orchids, the roots do better for a substantial compost, provided they can be induced to take to it with a will, but a plant with its roots only occupying about half the compost allowed it never holds itself steady in the first place, and, owing to the unoccupied material getting sour, the roots on approaching it lose their tips and die back. The preparation of the compost then and the size of the pot or basket used will depend upon the health and vigour of the individual plants. The atmosphere about the plants must always be kept moist, especially while young growths are forming. In a dry atmosphere they are never satisfactory, the pseudo-bulbs seldom swelling up to their full size, and the foliage is liable to insect attacks. So, too, in a very light house; the plant likes shade from summer sunshine, air and moisture always about the foliage, and plenty of water to the roots. It is the practice of many good growers to surface the compost for this and similar Orchids with Sphagnum Moss in order to retain moisture, this growing up around the base of the bulbs and helping materially to keep insects in check. So far it is very good, but a little of it must be

removed on the approach of winter, as it holds more moisture than is required by the plant. With regard to temperature the plant is not fastidious, but for preference a house devoted to Brazilian Cattleyas and Lælias should be chosen where the minimum night temperature is about 55°. II. *Brocklehurstiana* is a native of various parts of Brazil, and although it first flowered in this country in 1841 in the collection of the gentleman whose name it bears, it had previously been grown on the Continent. II.

Dendrobium Farmeri.—Apparently many plants of *D. thyrsiflorum* and *D. densiflorum* are sold as *D. Farmeri*, as frequently I have received flowers of these species labelled *D. Farmeri*, the correspondents asking the difference between them. The true *D. Farmeri* has loose racemes of pale yellow flowers, the disc of the lip deeper than the other parts of the flower, and, though some varieties bear a resemblance to the other species named, they are totally distinct from either. As a rule it flowers later in the season, and is a very

species, for it is easy to tell at a glance whether or not a plant may be included in it. The sepals and petals are usually of a soft rosy blush, occasionally spreading well, but often only partly opening.

Disa Veitehi.—Many growers are far from successful in cultivating the richly-coloured *Disa grandiflora*, and, in fact, are in the habit of purchasing plants frequently only to see them flower well about once or twice and after that dwindle away. In this hybrid Messrs. Veitch have given us a plant equally showy and beautiful, but with a much better constitution, or, rather, more amenable to culture, for the old species is vigorous enough when well grown. *D. Veitehi* is a hybrid between *D. grandiflora* and *D. racemosa*, a species noted among *Disas* for its ease of culture. The sepals are bright carmine, the inner portion of the lip nearly pure white, with an abundance of crimson spots. The plant may be freely propagated by means of offshoots, and these rapidly grow into flowering plants in a cool, moist and shady house if arranged

old material was removed and fresh substituted, this keeping the plant in good health. It is a native of Java, and was introduced by Messrs. Williams and Son, of Holloway.

FLOWER GARDEN.

DICTAMNUS FRAXINELLA.

(DITTANY.)

THE *Dictamnus* is, perhaps, among the best known of old-fashioned perennials, and as such often figures in wayside gardens in rural districts, where perchance the plants have been for years. Few plants resent constant interference more than this. In these respects the *Dictamnus* is on a par with the *Paeonia*, and, once well planted in deep soil, it may remain many years without disturbance. I remember some fine examples of the coloured variety that attained to fully 4 feet high and as much through, the plants occupying a position near the margin of the lawn in a large garden near London, where hardy plants were generally well cared for. The plants in question were placed originally one in the centre of each bed, other plants for the time being being planted around till the *Dictamnus* attained a good size, when the whole bed—a circular one—was given up to the plant in question. The *Dittany* is well suited to grouping on the grass, and tells to advantage especially where a sort of serpentine walk forms crescent-like recesses in the shrubbery border, and therefore on the grass which acts as a foreground. In such places good bold perennials are often effective, and where more than the ordinary care is taken in planting them, the reward will come in greater vigour and finer specimens generally. One good point concerning it may be mentioned: it is its self-supporting character, no sticks or supports of any kind being needed. Just now the red and white forms of this plant are at their best, and where good plants exist they are very showy.

Planting may be done in autumn or spring, but in the spring it should not be too long delayed, as the plants may suffer from a dry summer. Autumn planting is preferable, provided a deep bed of soil, which, if heavy or clayey, may be lightened with road-grit and leaf-soil can be given. In the matter of soil, however, these plants are not at all difficult to please, seeing how they luxuriate in common garden soils in various parts of the country. The *Dictamnus* may be increased by seeds or division, the former preferred. The seeds should be sown in the open ground as soon as gathered. A strong odour that is inseparable from the plant pervades the roots as much as the branches, and by which it may be readily recognised without seeing it. This odour is by no means unpleasant, but varies in its intensity. E. J.

Columbines.—How strange it is to find that there are in gardens myriads of flowers, costly and otherwise, grown, too, with exceeding care and trouble, not one of which exhibits that singular grace, elegance, and beauty the hybrid *Aquilegias* possess. It does not now matter how originated; it is enough to know that we have these hardy flowers in almost wondrous profusion, and that from a packet of seed costing, perhaps, one shilling may be obtained 100 plants that will in two years rival in beauty any garden flowers we have. Seed sown now in a box, in pans or under a handlight, so as to enable the soil holding these hard-shelled seeds to be moist, will give strong plants to put out in October. These will bloom moderately in the following

Flowers of the *Dittany* (*Dictamnus Fraxinella*). From a photograph sent by Miss Hutley, Derward's Hall, Bocking, Braintree.

fine species. It is a native of the Khasia Hills, whence it was introduced in 1847.

Cattleya Mossiæ aurea.—As in many other varieties of this species, the individual plants vary considerably, and, as a rule, the flowers are under the average for size. The sepals, too, often lack the width seen in the best varieties. A small, newly-imported plant now in bloom with me for the first time is much finer than usual, the yellow zone on the lip being large and spreading, and the whole flower of good size and substance. The *aurea* varieties have a very distinct appearance from all others, and a few plants help to brighten up a group of the species. It seems hardly worth while splitting these up as is done and labelling *aurea grandiflora*, *superba*, and others which differ little except in size from the type, but one, *C. aurea marginata*, as I noted it recently, seemed worthy this distinction. The lip was large and finely fringed, and the side lobes had a broad wavy margin of clear golden yellow. At all events the *aurea* group is quite a distinct section, and almost as clearly defined as some

close to a ventilator or in some position where the air current will play freely about the foliage. The best compost for it is peat fibre, a little leaf soil, and clean fresh Sphagnum Moss. If planted in pans with perforated sides there is less fear of the young shoots being smothered, as they find their way out through the holes in the sides. This hybrid first flowered in 1891.

Vanda limbata.—This is a pretty species but seldom seen in cultivation. The flowers occur on short racemes, and on the inside of the segments are of a deep reddish tint, margined with yellow, the reverse pale rosy purple. It is a fairly stout-growing plant with green leathery leaves, and delights in ample warmth while making its growth. The compost should consist largely of Sphagnum Moss and charcoal. Water must be freely given during the summer, and light dewings overhead help to keep insects in check. A plant I had under my care some years ago did well in a house devoted to Phalenopsis and tropical Cyripediums, where it was suspended not far from the roof-glass. Each year a little of the

spring, and quite luxuriantly for some three or four succeeding years. It is wise, however, to make a small sowing annually, and outdoors this may be best done in the early summer.—A. D.

Lupinus polyphyllus.—The herbaceous Lupines are worthy of a little more attention than they have received, and anyone would do a great service who could gather together and grow a collection of the species available. Occasionally in botanic gardens one meets with a few plants not usually seen, but the number grown in these collections is very limited. Note that I have yet seen appear likely to drive out of cultivation the old *L. polyphyllus*, which is generally represented by three colours—blue, white, and blue and white. Of these I have generally preferred the bicolor form as being brighter than the first, and because the white variety has usually a provoking habit of dropping some of its flowers before all are expanded, and so spoiling the symmetry of the spike. The other day in going through the Daisy Hill Nursery, Newry, I observed one of the species, and on remarking to Mr. Smith that the genus wanted looking up and improvement, he led me to a bed of seedling *L. polyphyllus* then in full bloom. The plants formed a fine sight, as not only was there variety in the size of the flowers and the length and density of the spike, but also in the coloration. Among the whites, while some displayed the fault already complained of, others were free from this defect. There were some pretty shades of blue and some tints of purple besides the pleasing bicolor. A bed of these fine seedlings on the grass or in the shrubbery would look well. Others who have time and space might well devote some of both to raising seedlings of the many-leaved Lupine.—S. ARNOTT.

GUNNERA MANICATA IN IRELAND.

THIS Brazilian Gunnera when well grown is indeed a magnificent and imposing plant. Young specimens give no idea of the effect of a well-established plant in congenial soil and surroundings and receiving regular attention in the way of manure. I question if finer specimens can be seen anywhere in the United Kingdom than in Ireland. For waterside planting it is a favourite there, and nothing can surpass the beauty of a huge plant on a promontory or an island on a lake. I am not sure, however, that it is not being too frequently planted in this way, fine though it is. The individuality of lakes and ponds becomes lost unless some originality is displayed in planting, and one is disposed to fear that *Gunnera manicata* is likely to be too frequently seen in some districts. This should not, however, tell against its introduction into parts of the country where it is little known and where its presence would create a new feature of the highest order. On a previous visit to Irish gardens I was much impressed by the way in which *G. manicata* was grown there. This year the impression was strengthened, although my engagements did not permit of my revisiting the finest specimen I have ever seen. This is at Narrow Water Castle, not far from Newry, where there is a plant of truly magnificent proportions. I am unable to give its height or the space covered by the leaves at the base, but its beauty may be surmised when one is able to tell that some of its leaves two years ago were 9 feet in diameter. It was in a specially favoured position, but much of its size is due to the careful way in which its wants are supplied. It appears that this fine specimen receives three loads of cow manure every year. I am told it is even finer this year. There is another very fine specimen in the noble gardens of Lord Ardilaun at St. Anne's, Clontarf, Dublin, where it is planted in a most skilfully chosen position by a sheet of ornamental water. It is cared for as liberally as that at Narrow Water, and may in the course of a few years assume as imposing dimensions. At Trinity College Gardens there is another very large specimen by the side of the pond, and when the Water Lilies are in full flower their

beauty is emphasised by the contrast with the rugged, massive foliage of the Gunnera. At Straffan House, Co. Kildare, Major Barton has also a magnificent plant, which I was not near enough to judge of properly, but which in the distance looked of great size. The same may be said of a good specimen by the side of a sheet of water in the Phoenix Park, Dublin. In other gardens I saw smaller plants, but none were so fine as those I have mentioned.

This Gunnera is hardy in the south of Scotland also: and along the west coast, with shelter from high winds, which would break or disfigure the great leaves, it ought to be more generally grown. The conditions under which this Gunnera does best seem to be shelter from wind, a climate mild in spring, and planted in such a way that the plant itself is on a small mound, the roots having free access to moist, peaty soil beneath. Although the great beauty of the Gunnera consists in its foliage, the inflorescence attracts attention by its curious appearance as it stands up among the lower leaves. Wherever a good plant is seen it commands almost universal admiration by its tropical look and majestic mien.

S. ARNOTT.

THE MADONNA LILY.

YEAR after year the stems and leaves of the Madonna Lily have been attacked, and in some seasons all the flowers have been spoiled by disease. I have long been an advocate of a system which was I believe first recommended by "E. J.," viz., lifting and sun-drying the bulbs whenever the disease has been very prevalent, for by keeping them out of the soil long enough to prevent autumn growth the spring attack does not commence so early and the spikes get forward enough to produce flower-buds before the attack becomes severe. Real progress in combating the disease has, however, been slow, and the spores must have wonderful vitality, as they have always come again with more or less force. For a few years past I have given a change of site each year, and have fancied that the disease was slowly disappearing, but scarcely dared hope that it would be beaten. I can, however, record that this year in a bed of plants containing over 300 spikes not a dozen disease spots can yet be found, though the flowers are on the point of opening, so that one may surely expect a good season and a lessening of the crop of disease germs for next year. The bulbs were planted thickly in a specially prepared bed, where Lilies had never been before, the top soil being thrown out and a heavy coating of manure dug into the bottom spit. To test the influence of deep v. shallow planting the bed was dug so that the bulbs at one end were only just covered with soil, and the depth was increased by a graduated fall to 6 inches at the other end. The only difference noticeable is that the shallow-planted bulbs have the taller spikes, though the difference is so slight that probably if measured from the bulb instead of the surface there would be nothing to choose between them. Should no disease appear, I intend to leave the bulbs alone this year, as something in height and in number of flowers is lost by lifting; but this is better than having plants eaten up by disease, and if one can by persevering master the enemy, it is worth trying. There are many conflicting opinions among keen observers as to the best means of combating the Lily disease, and I do not wish to assert that the deductions I have made from the results obtained are right. It may be that other unknown influences have been at work helping to secure immunity from disease this year, for the lifting and drying have been tried and found wanting in other places and other years. Still, one failure in an infected garden

does not disprove the value of the practice, and I simply give the above as a record of things as they appear here, where the case was so bad a few years back as to make it appear that the Lilies were doomed. There has been no change of or addition to the stock in the meanwhile to account for change of condition, and disease is still prevalent in the neighbourhood.

Livermere Park.

J. C. TALLACK.

FLOWER GARDEN NOTES.

HARDY PLANTS IN FORMAL BEDS.—Beds of formal character that some years ago were filled respectively in autumn and spring with the usual winter and tender plants have for some time been tenanted with hardy subjects. Since the appearance of flower on the *Doronicums* and *Tufted Pansies* a number of them have been bright. They are just now very gay and will last to the end of the summer. The planting of such beds with hardy things requires a little consideration and care, especially if the said beds are small and rather close together. Tall things of straggling habit are not advisable, and a study as to the different shades of colour likely to be produced is necessary. The large *Doronicum* is still flowering freely on a carpet of *Tufted Pansies*, and seems likely to last for some time. This long-sustained display on the part of this plant is perhaps not sufficiently recognised. It is a valuable characteristic, and its usefulness is thereby considerably enhanced. *Campanula persicifolia* and *p. alba* on carpets respectively of *White Swan* or *Violetta* and a good purple *Pansy* are suggestions for beds of comparatively small size that will be very pleasing, and this season the old *London Pride* (*Saxifraga umbrosa*), considerably later than usual, is looking very well with the blue *Campanula*. *Pinks* are just now at their best, and a fairly dense planting of *Pinks* in full flower is hard to beat, appealing, as it does, alike to the sense of sight and smell. For varieties like *Mrs. Sinkins* or *Her Majesty*, if any plants are wanted by way of contrast, I would strongly recommend the deep foliage *herbaceous Lobelias*, the contrast being both striking and effective from early in May right away to late autumn. For sorts like *Anne Boleyn* and *Ascot* other subjects are not so easily found, as anything planted to contrast with the flowers would perhaps not be seen to the best advantage with only the foliage. If *Carnations* are employed in beds in prominent places where anything in the way of gaps has to be studiously avoided, it is well to defer planting until spring, and also, if possible, to have a certain number of each variety reserved in nursery beds from which to draw in case of failure. For beds of somewhat larger size than those already under consideration, a combination of *Pyrethrums* and *Tufted Pansies* may be strongly recommended. Bold clumps of the former in selected shades, as *Aphrodite* (white), *Solfaterre* (primrose), *Florentine* (blush-white), *Celia* (pink), *Ormonde* (bright rose), and *Melton* (crimson-scarlet), may first be planted, and the *Tufted Pansies* filled in in variety as the taste of the planter may suggest. A thorough soaking of water may be recommended if the weather prove hot and dry, when the beauty of the first flowers is slightly on the wane. By this means the old foliage is preserved until the young growth has made fair progress, and with the necessary attention given to the *Tufted Pansies* the beds will be attractive until quite the end of the season. The claims of *Antirrhinums* and *Pentstemons* have already been advocated in a note on plants obtained easily from seed. It is only necessary to add that they make very charming beds, and that their endurance will be considerably prolonged by a rather early removal of the central spike as soon as the bottom flowers show signs of dropping. Some larger beds can also be devoted to the earlier flowering *Phloxes*, of which very fine varieties are now available in colours ranging from pure white to a deep purple, many different shades of mauve, rose and pink intervening. I have noted "earlier

flowering Phloxes," but although they are earlier in flower than the section more generally known, they last a long time. If decaying pips are picked from the main truss, back buds will push their way to the front, and if the truss itself is nipped off, smaller spikes will develop from its base and prolong the display. Many more things might be advanced as suitable for the purpose in connection with the species already enumerated. There are, however, a wealth in colour and a variety in shade in these sufficient to make any ordinary sized formal garden gay from spring to autumn. I should like to suggest that in all flower garden arrangements it is advisable to choose flowering plants as much as possible rather than those things only noticeable for their foliage. I mean, for instance, that white Tufted Pansies, Pinks or Antirrhinums are preferable to *Dactylis glomerata* or *Centaurea candidissima*, and the dark-foliaged perennial *Lobelia*s to *Iresine Lindenii* or the dark *Colerus*.

Seedling hardy plants noted in a recent number are now well on the move. Attention should still be given to partial shade during bright weather and (in the case of tiny seedlings) careful watering, the object being to keep the plants growing steadily without the tendency to draw. As soon as the young plants get a hold of the soil, by all means run through them to remove weeds. If the latter are allowed to make headway, their removal is only effected at the cost of considerable root-disturbance of the young seedlings. Home-saved seed of *Polyanthus* has come up remarkably well, and as it was saved from good strains in half a dozen different shades, I am looking forward to some fine flowers. E. BURRELL.

Clarmont.

Pyrethrums.—It is surprising what a single crown of a *Pyrethrum* will do in a year provided it has not been starved in the pot a whole season; and all such having been lifted, divided, and planted into good rich ground, will be infinitely superior a year hence to a spade-divided clump five or six times the size. The quality of the blooms, as also the quantity, will also leave no doubt as to the superiority of the system now advanced. Like many other hardy plants that grow freely, these *Pyrethrums* may be left too long without division, and where this is the case the flowers are poor and insignificant. Three years as a maximum in one spot is long enough, and far better, as also easier of resuscitation, where a rigid system prevails of breaking the plants up into quite small pieces every two years. By following this method, there need be no lack of these fine border flowers in June.

Jankæa Heldreichii.—It may, perhaps, interest some of your readers to learn that this has this year for the second time flowered freely and strongly at Ketton. The position and the appearance of the plant are well shown in the photograph I send you. The plant has been where it now stands for, I think, six years and has not much increased in size; it showed no sign of flowering until last year, when there were some five blooms borne on three stems. This year there are five stems, bearing eleven flowers. The colour is deeper than that of *Ramondia pyrenaica*, which is growing near it. Another plant, bought a year or two before as a seedling, increased to several crowns, but was lost by being removed to a more sunny position, which it was hoped might induce a tendency to bloom, which it had never shown in its original and apparently more congenial shade. This species is, I am told, now scarce in the trade, and one is averse to running the risk of losing even one plant by experiments in cultivation. I shall be glad, therefore, if any person who has been successful in growing it can give information as to its wants and the best methods of propagating it.—(Mrs.) SUSAN H. BRIDGES, *16, Lower Berkeley Street, W.*

Garden Pansies.—Although many of the Pansies proper are of weak constitution and not able to hold their own against the tufted kinds, there is always the chance of raising something

fine in colour and vigorous in habit that is as hardy and continuous in flowering as the latter, yet preserving the round form and large size of the flowers. When I took charge here I found a seedling *Pansy* under an old espalier *Apple* tree that bloomed very profusely all through the summer, and propagated from it freely. It has been a glorious sight during the present spring, and is now a perfect mass of colour. The blossoms are mauve with bluish purple markings, but it is of a somewhat sportive character. The broad lines of mauve were a lovely contrast some time ago with the yellow *Alyssum saxatile* on each side a walk in the kitchen garden, and on another border I have had two-year-old plants—masses nearly a yard across alongside various other spring flowers. All the latter, of course, are gone, but the *Pansy* is as brave as ever, and on account of this continuous blooming, the neutral tint of the flower that seems to go happily with anything else, and its splendid constitution, I would rather lose any other plant I have than this.—H.

Pink Mrs. Sinkins.—Although the flowers of this variety are larger and equally as sweet as those of the old garden *Pink*, there is still room for both. The continued rains have somewhat marred the appearance of both, but they are very beautiful in large clumps, formed by planting about a dozen young plants and allowing them to stand three years. The flowering will now be soon over and propagation may commence. They may be grown from cuttings easily, this being less trouble than layering, and where no reserve ground exists, it prevents the unsightly business of moulding up and pegging. The cuttings will consist of the short, stubby side growths stripped off with a little of the old wood, and my plan is to select a semi-shaded border and mix with the soil equal parts of old potting bench refuse and burnt earth, preparing this a few days in advance and watering well should the weather be dry. The cuttings are dibbled out rather closely and covered with hand-lights or small frame-lights. If lights are plentiful, a more open spot may be chosen, the cuttings inserted at greater distance, and the lights removed when the cuttings are well rooted. But here it is found more convenient to transplant to an open place as soon as well rooted, this resulting in strong, yet compact little plants for grouping as described, or with the *Mrs. Sinkins* for potting for early flowering. Where the soil is inclined to be heavy and bad working, the addition of leaf-soil, burnt refuse, or anything that will make it more friable is well repaid, and in this mixed class of soil the *Pinks* grow well. They like a sunny, open position.—H.

NOTES ON HARDY PLANTS.

Saxifraga Cotyledon gracilis.—So far as I have been able to find out, this third name has little or no printed authority, which is saying a great deal, as, perhaps, no genus of hardy cultivated plants has been more overdone with names authorised and unauthorised. Those, however, who knew the late Mr. Niven, of the Hull Botanic Gardens, will allow that he was no mean authority on *Saxifragas*; his collection was complete, carefully named, and splendidly grown. I believe the present plant was one of his own raising; anyhow, I had it from him with the name as above. He said it would be worth looking after. It may be described as *S. Cotyledon* in miniature, a good kind, with both flower and leaf features to commend it, the flowers, like those of *S. Cotyledon*, pure white, the panicles dense, feathery, and only 8 inches or 10 inches high. The rosettes are slightly over an inch across, of a deep green shade, and vividly and evenly bedecked with silvery dots around the edges. It is a slow grower, but not apt to go off like some of the hybrid forms of the *Aizoon* section, like, say, *S. Macnabiana* or *S. Cotyledon* itself, which is very liable to take the *Saxifraga* fungus. I hope that others may have had the same plant from the Hull collection, and that it may

find its way into commerce, as it so well deserves.

Ranunculus Macaulayi.—Who can say if this is more than biennial, and even then if it is capable of living in a severe winter out of doors, and, worse still to my mind, it is not a plant of much promise, for all the great praise it came to us with? The fact that I ask these questions about it suggests that the plant may not have had a happy home here, and yet it has been in commerce now three or four years and nothing seems to be said of it.

Myosotis Traversi.—This is a dwarf and distinct *Forget-me-not*, its chief feature being the small yellow flowers. It grows here about 8 inches high, has an oblique habit with its dark-coloured, thick stems, which have blackish hairs. The stems are further notable from being much forked, long-jointed, and having a very few small leaves.

Phyteuma comosum.—When once you get this rare alpine going, it proves a reliable plant against either drought or wet, though it is a slow grower. The way in which it makes itself comfortable gripped between two stones and with its caudex well kept up not only enables it to withstand to some extent both heat and wet, but tends considerably to its interest as an object of special culture. A neater or more characteristic plant we do not possess as yet for the rock garden, nor a more charming or curious flower. Though a six-year-old plant might easily be covered by the two hands, and sometimes one hand, it manages to make itself conspicuous to anyone when in flower, its thick Holly-like leaves being just as distinct as its other parts.

Woodville, Kirkstall.

J. Wood.

NOTES AND QUESTIONS.—FLOWER

Chalk for *Gentiana acaulis*.—In answer to "S. T.," Uxerstone, in *THE GARDEN* of June 19, we are very much on the chalk here. *G. acaulis* grows and flowers freely, but the leaves and blooms are not so large as I have seen them in richer soils.—W. H. S. M., *The Down House, Dorset.*

The white Foxglove.—In large borders near shrubberies or in any semi-wild position the pure white flowers of this plant are very effective, but if planted in the herbaceous border, care is necessary that it does not overrun and spoil choicer things. It is planted here in a long border principally devoted to *Rhododendrons*, which is top-dressed annually with leaf-mould, and it makes immense plants that are very fine seen from a distance.—SUFFOLK.

***Gentiana acaulis* in peat.**—A lady recently told me that with her *Gentianella* succeeds remarkably well in pure peat, the plants increasing and blooming freely. I must confess that I should never have thought of using peat for this hardy flower, which I have always considered benefited by the presence of lime in the soil. We thus see how impossible it is to lay down fixed rules with respect to the rooting medium best suited to any particular plant. The plants in question are set round a *Rhododendron* bed, a good position for anything that the soil suits.—J. C. B.

Three good showy hardy border plants.

—The old double white *Rocket* (*Hesperis matronalis flore-pleno*), *Lychmis Viscaria splendens fl.-pl.*, and *Gampania dahurica* are valuable in the hardy plant border at this season of the year. In these three plants we have three decided colours—rose-pink, deep blue, and white. They are also useful for cutting and will stand a long time in water. Another recommendation to them is they do not need a lot of stakes to keep them up. They are easily propagated by cuttings or division. To see these at their best they should be grown in big masses from 2 feet to 4 feet across.—DORSET.

Lilium pomponium verum.—Towards the end of June this *Lily* is at its best, and in the border it makes almost as bright a show as will *L. chalcedonicum* later on. It reaches, as a rule, a height of a yard or more. The individual

flowers are thick in texture, the segments gracefully recurving, as in the different members of the Martagon group. This Lily does not increase very quickly. The smell of the flower is heavy and unpleasant. In any selection of hardy border Lilies this should have a place. Though belonging to the Martagon group, the leaves are not arranged in regular whorls as in the true Martagon.—H. P.

DESTROYERS.

THE ASPARAGUS BEETLE.

(CRIOGONIA ASPARAGI.)

ACCORDING to a leaflet just issued by the Board of Agriculture, this beetle often does much harm to Asparagus, especially in beds which have been established from one to three years, by eating and disfiguring the heads as they are formed, and later on by attacking the stems and seeds, of which it is particularly fond, both in the beetle and larval stages. In the beetle stage the insects bite the tender Asparagus heads while these are yet underground or only just showing above the ground, making brown patches upon them and spoiling their appearance for market. Later on the beetles eat the feathery shoots of the plants, as well as the large round seeds, to which they are very partial. A beetle will eat a considerable quantity of the tender feathery shoots in the course of a day. The larvae are also most voracious, and sometimes, in bad cases of infestation, the long stems of the plants are left completely bare of foliage by successions of larvae. The Asparagus beetle is common in the southern, eastern and western parts of England, but it is rarely found in the northern districts. Canon Fowler, in his Coleoptera of the British Isles, states that he does not know of a record from any locality farther north than South Derbyshire. It is known in France,* Germany and Italy, and probably throughout Europe. In the United States, where it was introduced from Europe in 1858, it has spread very rapidly. It was first seen at Astoria, in Long Island, where Asparagus is largely grown, and by the year 1862 the beetle had spread throughout the Asparagus beds of Long Island.

LIFE HISTORY.

The beetle is about a quarter of an inch long and comparatively narrow in width. Its body is shiny black, with a blue tinge; its head is black; its ten-jointed antennae are dark brown; its thorax is red, with two black marks or lines upon it; and its wing-cases have outer margins of orange colour and black inner margins, and there is a transverse bar of black across them. Upon each wing-case there is a row of three yellowish or lemon yellowish spots or patches, which, with the transverse bar and the black margins, form the figure of a cross; hence the beetle is termed "Cross-bearer" (the French call it "Porte-Croix"). Eggs are laid by the beetles in the early spring upon the heads, shoots, and feathery foliage of the Asparagus plants. The eggs are brown, long, and somewhat cylindrical, being glued by their ends to the plants, usually in rows of three to five, but frequently they are placed singly. Larvæ come forth in from eight to ten days, and immediately begin to feed upon the Asparagus. The larval stage lasts for fourteen days, or for about this period, when the larvae fall to the earth and undergo transformation just beneath its surface in a slight cocoon. The number of broods

* Boisduval says that the Asparagus growers of Argenteuil, in France, complain that it is very detrimental to their Asparagus culture.

appears to depend upon the weather and the supply of food. Pupæ and larvæ are frequently found upon the plants until the middle of October.

The larva, which is about the fifth of an inch in length when extended, is of a dark olive-green colour, and usually has a black mark upon its back. It is thick, fleshy, and somewhat slimy, with a shiny black head and three pairs of shiny black legs: the lower end of its body is unusually prolonged to help locomotion and to enable the larva to cling to the stems and shoots of the Asparagus. There are also two rows of tubercles along the body, which have the appearance of rudimentary pro-legs. It has not been definitely decided whether this insect hibernates in this country in beetle or pupal form, but the evidence tends to show that here, and in other European countries, it exists during the winter in the latter form in the earth. The majority of the American entomologists, including Fitch, Lintner, and Chittenden, hold that the winter is passed in beetle form. Dr. Lintner says: "The beetles destined to continue the species survive the winter in dry sheltered places, as beneath bark, in crevices of wood, and under the boards of buildings." If hibernation takes place in the pupal form in England, the transformation occurs very early, as the beetles attack Asparagus plants directly they shoot and before the heads are above the ground, and, as is well known, Asparagus begins to shoot after the first few warm days in spring.

METHODS OF PREVENTION AND REMEDIES.

In the first stages of this attack, that is, when the beetles are underground and feeding upon the juicy parts of the heads of the Asparagus as they are formed, it is difficult to deal with them, though at this period they do considerable harm by making the heads brown and spotty. It is desirable to leave a few heads uncut in every bed where there is infestation as traps for the beetles, which get up the feathery shoots and branches during the day for pairing and the deposition of eggs. In the course of eight or nine days these plants should be brushed off close to the ground and burnt. Another set of heads should be allowed to run to shoots, which should also be brushed off and burnt. Beds of young Asparagus plants are most liable to this attack in the first year or two, when only the strongest heads are cut for market, as the beetles like the succulent shoots of young plants. It would seriously injure the stocks in newly-made infested beds to cut off their shoots. In such cases it would be better to beat the feathery shoots smartly with sticks, and to tread heavily round the plants to crush the larvae. Very finely powdered lime dusted on infested plants would also be efficacious, as it would adhere to the slimy bodies of the larvae. The lime should be applied as soon as the larvae are noticed, and the application repeated at intervals. In small beds, and in beds of young plants, hand-picking, both of beetles and larvae, would be useful, but this operation is too costly where Asparagus is largely cultivated. In extensive beds the remedies to be employed are liming and beating infested plants and trapping, as indicated above, by letting some heads grow into plants and brushing them off and burning them. Syringing can be adopted in gardens. Where Asparagus is grown upon a large scale this process is more difficult, as the plants are not set in rows, but it may be effected by means of knapsack spraying machines. Kerosene emulsion, consisting of two gallons of kerosene oil and half a pound of soft soap dissolved in a gallon of soft water, may be used for

spraying. The soap should be boiled, and while boiling the kerosene should be poured into it and churned up with the soap until it is thoroughly incorporated. The mixture should then be diluted with 15 to 20 gallons of water. Paris green is also a valuable remedy against these and other insects which feed upon foliage. It may be used at the rate of one pound of Paris green to 200 gallons of water. It is better to put one pound of fresh lime with the Paris green. This mixture can also be put on with a knapsack machine. As this is poisonous, it should not be used till the Asparagus has been all cut. Spraying should be carried out before the foliage has become thick and strong. It will be necessary to repeat this operation, and it would be effective against both beetles and larvae. It would be desirable to examine the roots of Asparagus obtained for making new beds, as the pupæ may be conveyed in these. In the United States infestation is extended in this way.

GARDEN FLORA.

PLATE 1178.

TULIPA KAUFMANNIANA.

(WITH A COLOURED PLATE.*)

AMONG the many rare and beautiful species of Tulip in cultivation in our gardens to-day the above holds a foremost position in point of merit, as also in the handsome appearance of the plant when in flower. As may be gathered by a glance at the unopened bloom in the accompanying plate, the flower is of large proportions generally, an item which good cultivation appears steadily to favour as the species year by year become more and more naturalised to British gardens. It frequently happens that some of the earliest flowered examples of any particular species do not impress one with either their distinctness or the representations that may have accompanied or preceded the importations that any given kind is likely to prove an acquisition. Further experience and acquaintance of the kind have, however, proved the reverse. The species now under notice is one of those that with its earliest flowering gave indications of a rather inferior article, while the flowers that have resulted from cultivated bulbs fully bear out the remark at the head of these notes. Among the early kinds it is certainly one of the most handsome and as striking as it is distinct and pleasing. For several years past the species has flowered grandly both at Kew and at Ditton, and, as far as could be determined by growth and flowering, it is a good doer, generally strong and robust, in each of the instances referred to. The species shows but little inclination to vary, and at Kew, where during the past year or two a nice little group has flowered well, the same characteristic is prominent. In the "Dictionary of Gardening" this species is described as having a "bright yellow perianth," and the segments oblong, acute, "without any basal blotch." Two varieties are also described in the same work, but none of these generally agrees with the flowering examples I have seen, and of which the coloured plate to-day is a faithful reproduction, with one exception, perhaps, and that the pure white shade to which prominence is given in the flower on the right hand side of the picture. Indeed, it is the creamy white shade of the broad reflexing segments, coupled with the golden orange base, that renders the

* Drawn for THE GARDEN by H. G. Moon. Lithographed and printed by J. L. Goffart.

Begonia

flower as a whole so very conspicuous, if not unique. The widely-open flowers are often of great size. In the bud state, too, the reddish carmine tint that pervades the margin of the outer segments, so well shown in the plate, is very attractive.

So far as its culture is concerned, it differs in no wise from other kinds, all of which prefer good deep soil. *T. Kaufmanniana* is a native of Turkestan, and when in good condition attains 8 inches or so high, flowering usually at the end of March or early in April. Apart from the forms referred to above as mentioned in the "Dictionary of Gardening," and which, according to the names, have white and yellow variegated flowers respectively, is a third kind, called *T. K. pulcherrima*, said to be probably a hybrid between the above species and the well-known and gorgeous-flowered *T. Greigi*. This I do not remember to have seen. It is, I believe, one of M. Max Leichtlin's introductions, who may be able to give some information concerning so interesting a cross. The following are worthy companions to the above handsome kind: *T. Batlini*, a lovely soft yellow; *T. Kolpakowskiana*, vermilion, very striking; *T. saxatilis*, rose and yellow; *T. violacea*, the earliest flowering of all, colour reddish carmine; *T. vitellina*, pale primrose; and *T. retroflexa*, a lovely clear soft yellow.

E. J.

THE WEEK'S WORK.

KITCHEN GARDEN.

SPRING CABBAGE.—Preparations must now be made for the spring supply. Most growers do not care to rely upon a single sowing, as, if too early, the plants get too large and run. Again, if too late, the plants are not strong enough to stand our variable winters. As regards varieties there is no need to complain, as, given good soil at the start and attention to the plants, there will be few losses. This spring I do not know what I should have done without a good breadth of spring Cabbage, as the green crops ran to seed quickly, and the Cabbages, though a little later than usual, were most serviceable. I began cutting *Ellam's Early Dwarf* the second week in April. I do not think there is any Cabbage to beat *Ellam's* for spring use. I am aware there are others which run it very close, but those who do not care for variety may rely upon the kind named. The nearest in quality and earliness I have grown is *Sutton's Earliest*. This, like *Ellam's*, is remarkably dwarf, with scarcely any outer leaves, and *Favourite* is also valuable for sowing at this season. In the north, *Mein's No. 1* is a great favourite and an excellent variety. This with me is a little later than *Ellam's*, but equal in quality and very hardy. I make my first sowing during the second week in July, and place much importance upon the date, as it makes a great difference in the size of plants. It should be borne in mind that a friable soil well manured is needed, as the seedlings must make a quick growth. I always sow broadcast and allow ample space, and, should the weather be dry, moisture will be needed to assist germination. In light soil I find it advantageous to make the seed-bed fairly firm, and by so doing the plants can be lifted with more fibrous roots, and do better. In heavy, clay land one may with advantage improve the seed-bed by incorporating any lighter soil. I have used old potting soil and limestone road scrapings to advantage. I always make a second sowing from the 20th to the 30th of this month of the same varieties, as, should the plants from the first sowing be too large, these never fail. On the other hand, there are considerable advantages in sowing twice, as from the earlier one heads may be cut at the end of March in a favourable season; the latter will give a succession. I

plant a smaller portion of the first sowing than the second if the plants are at all large when ready to plant.

CABBAGE QUARTERS.—It is full early to refer to the planting before the plants are through the soil, but it is not out of place to advise as to the quarters needed for the plants. My earliest Cabbages invariably follow spring-sown Onions. This crop is much later than usual, but will be cleared in time for the above plants. By utilising the Onion quarter, the Cabbage is given the treatment it needs to build up sturdy plants, as mine being a light soil, it is made as firm as possible for the Onions, and the cleaning and thinning during growth make the surface firmer, so that it is in good condition, having been well manured for the Onion crop. I merely clean the surface, draw drills, and plant, as I find with a firm root-hold I do not lose one plant in a thousand by running, and severe frost does much less damage to plants grown hard from the start. Plants in recently-manured land make a soft growth. These lose a large portion of their leaves in bad weather, and are much weakened in consequence. Many may not be in a position to give the quarter I have advised. Early next spring when growth begins I feed freely with liquid manure, or with guano and fish manure failing the first-named. Small plants, like Cabbage, do not need strong manures at planting, as, having the winter to tide over, if too gross they bolt, and it is an easy matter to feed early in the year.

COLEWORTS.—I advised a small sowing of this useful vegetable a few weeks ago, and owing to the rainfall we have had of late, the plants will soon be in condition to plant out. It is surprising how quickly these plants grow when put out. Good land will give the best returns, as, unlike spring Cabbage, the earliest Coleworts may be cleared by November, so that it will be necessary to give land a good coating of manure to get a quick return. Though many only make one sowing, much better results are secured by having a succession, so that another sowing at the middle of this month will give ample planting material. In planting at this early season, 15 inches apart in the rows and 9 inches to 12 inches between the plants will be sufficient, the Rosette variety needing less space than the Hardy Green variety. This latter I advise for a later sowing, to give a supply before the spring Cabbage turns in. Coleworts do well on land just cleared of early Potatoes, and, if manure is none too plentiful, any good fertiliser may be used previous to planting. I spread on the surface and then lightly fork in.

LATE DWARF BEANS.—These are most useful in the late summer months, and if sown thinly there will be a good return. Many rely on the crop sown earlier for a supply, but the plants by the end of August are exhausted, and oftentimes red spider so attacks bearing plants in hot, dry weather that I have found it much more profitable to make sowings at this season for a full supply in late August and through September. My late Beans are now being sown on land that has borne a crop of Cauliflower. The position is a sheltered one. I advise a sheltered place, as should we get frost early in the autumn it is an easy matter to cover some short rows of dwarf Beans to eke out a supply. For present sowing, *Ne Plus Ultra*, *Perfection*, and *Early Favourite* are excellent kinds. The two latter produce larger pods than *Ne Plus Ultra*, but are dwarf and very prolific. If a large Bean is desired *Canadian Wonder* is one of the best, but it is not so good for late supplies as for summer cropping.

LATEST CROPPING PEAS.—For a supply from September to October it is well to sow the early kinds. It is now full late to sow tall kinds of the *Ne Plus Ultra* type. For this crop it is well to manure the land, a quick growth being necessary. My late varieties follow the early Potatoes, and being well manured the land will be in condition for a spring crop of early roots, such as early Turnips and Carrots. For present sowing *Chelsea Gem*, *May Queen*, and the *Michaelmas Pea* are excellent varieties, and do not take

mildew badly. These sown 3 feet apart and rather thin in the row will give a good return at the season named. To save time in dry soils I have soaked the seeds for a few hours previous to sowing, and secured a much quicker growth. Peas sown now need more care at the start, as birds are troublesome in country districts, and netting is a necessity. Drought also is a great enemy of the autumn Peas. It is well to sow in shallow trenches in light soil, and if labour is scarce it is a good plan to lay manure in the trench previous to sowing, placing a little of the top soil over the manure. If there is any doubt as to the vitality of the seed, it is well to sow thicker and thin after, as it will be too late to sow again if failures occur. As regards the position, much depends upon the soil and locality.

GLOBE ARTICHOKE.—These are now making a free growth, and will need feeding to get the best results, as, unless the heads are fleshy and succulent, they are not so valuable. Now is a good time to mulch with a fair thickness of rotten manure if the soil is light. I use cow manure, and find it of great benefit, as it keeps the roots cool in hot, dry weather. Few plants will better repay copious supplies of water or liquid manure, as owing to the abundant leafage the rain does not readily reach the roots. I mulch and then use the hose freely in dry weather. One thorough watering weekly will suffice, and the plants will give a large quantity of heads if kept well supplied with moisture. These plants will often produce too many heads, and in poor soils they will need thinning. It is also advisable to cut out the old stalks close to the soil after cutting, as these impoverish the plants if left.

LEEKS FOR SPRING USE.—I grow a goodly number of these for use in the early spring, as, unlike many other vegetables, these will continue growing through a mild winter. I am not much in favour of growing the huge roots often seen at exhibitions. Those late in the spring are poor in quality. There is no difficulty in keeping Leeks well into May if the roots are grown for late supplies. The Leek is most useful at the time named, as the green vegetable crop is getting scarce. An open quarter is best, and a liberal dressing of manure is needed. Many grow in trenches, and in light soils drills have advantages, as the moisture and food are more easily applied. Excellent roots may be grown on the flat in rows 15 inches to 18 inches apart. Previous to planting I have found it a good plan to draw drills. In planting, care should be taken to place the roots quite straight if a dibber is used. S. M.

HARDY FRUIT.

STRAWBERRIES IN THE OPEN.—**LAYERING FOR FORCING.**—In some cases this important work will by this time be well advanced, and in favourable localities, perhaps, finished. If so, all the better, as far as getting the work forward is concerned; but those who have had long experience know in practice that if all of the potting up into fruiting pots be completed by the first week in August, they will have nothing to fear as far as vigour of the plants and well-ripened crowns are concerned. All layering for forcing should certainly be completed by the middle of the month; therefore during the coming week it should be the important operation to be borne in mind and pushed forward. Commence by securing clean or as clean pots as possible (time in many cases will not allow washing now). Drainage may be dispensed with as superfluous, nothing beyond a small amount of Moss or rough soil, decomposed leaf soil, for instance, will answer the purpose well. Make the soil tolerably firm, however, so that the ball does not break to pieces when the transference into fruiting pots takes place. Old Melon bed soil of last year if still in reserve will answer well for layering, as a little manure in it will encourage root action, but do not in any case use any soil that may come to hand, for a good start in root growth is an all-important matter. Leave sufficient room when filling the pots for

watering. Some growers fill them full; this is a mistake, as may be seen at a glance: the trade even are apt to do this, and thus the young roots suffer. Either pegs or the time-honoured stone will answer for securing the runners. The pegs will hold the runners more securely where layering is being done upon beds still in bearing condition, but in other instances I prefer the stones, for the simple reason of expediency and of keeping the soil both moister and cooler where immediately in contact with the primary roots. Never depend upon second runners (*i.e.*, the secondary runners from the first ones) if enough of any kind can be had without its being done, as these never make quite such good plants for forcing. Rather cut them all off as the work goes on. Attend well to the watering every morning when it promises to be a hot day, and always every evening as the sun leaves the beds. In a fortnight, or at the most in three weeks, all runners that are well cared for will be fit for potting. As regards varieties there are a few which stand out prominently, as may have been noted by the readers of *THE GARDEN* from time to time during the forcing season now ended. Royal Sovereign is pre-eminently the first one to be chosen for the main stock of plants. It makes its runners in good time, and vigorous ones, too, if the plants be in good health. Last year my first stock of Royal Sovereign was taken from plants that had been forced and turned out six weeks or so previously. This year, however, the plants so planted out, instead of making runners, spent their energies in the production of a crop of flower-trusses, and that in spite of bearing good crops whilst in pots. Thus one cannot always depend upon the result of the previous year's experience. Last year the runners so taken were prominent the whole season through by their sturdy and well-advanced appearance. Next to the variety just named comes La Grosse Sucrée, which for first early crops in some cases has proved to be more reliable; it has with me. Its chief value is apparent for ripening up to about the third week in March. With me it does not make runners so kindly as in the case of Royal Sovereign, but not nearly so many are required. The chief value of Vicomtesse Hélicart de Thury is its greater reliability for autumnal fruiting when planted out—at least this is my experience of it. By some the fruits of this variety are preferred. Where this is the case by all means grow it and as well as possible. For later uses after the stock of Royal Sovereign is spent, three excellent kinds may be found in British Queen, Latest of All, and Gunton Park.

STRAWBERRIES NOW FRUITING AND OTHER STOCK.—Amongst these there will not be much to be done now, save to keep down the weeds where any appear and to water late varieties if they stand in need of it. Late kinds, as Latest of All and Waterloo, require a liberal supply of water for them to perfectly develop their crops. In spite of liming, slugs are still giving some trouble, so I have placed some more litter around the plants where the fruit was not too far advanced. Placed around each plant in the form of a support to the spikes which are borne down by their weight close upon the first mulching, this will help to keep the fruit cleaner and fresher. Whilst attending to the layering for forcing do not overlook the fact that layers from pots make the best plants also for new plantations in the open. It may take a little longer time even when work is pressing in other directions, but it is worth the effort to accomplish it, and in any case it should be done as soon as the crop is cleared off. Of course, where room can be given up to growing a stock of plants on purpose for layering, the flower trusses being cut off, it is the best plan to adopt, and I doubt not it might well be an extended practice, as more vigorous and rather earlier runners can thus be had. Where the old plants from forcing have been put out the watering must be regularly attended to until it is seen that they are well established, and even occasionally afterwards. Alpine Strawberries raised this year from seed are now establishing

themselves, after having been pricked out into Celery boxes, being for a few days kept close in cold frames. In another week these will be well exposed to keep them as sturdy as possible. Those a year older are now being gone over, all the flower trusses being removed to give them more strength for autumn cropping. These will then come into fruit towards the end of August or a little earlier perhaps. A mulching of leaf-soil, road scrapings, and old Mushroom-bed manure, into which the roots will soon find their way, is also being given. The mulching with clean litter will then follow as speedily as possible, the beds thus being completed for the time. Plants of the Alpine Strawberry that are two years old or a little more from seed are now bearing heavy crops and will continue to do so until the end of August. This year again these were ripe with Royal Sovereign. Do not attempt to raise a stock of the Alpine Strawberries from runners taken from old beds: it is utter folly to do it. This is the chief reason why the Alpine Strawberry has never been more popular than it has. Never go beyond taking runners from the seedling plants direct. It is worthy of note, however, that strong runners, if now taken off with roots and potted up into $\frac{1}{2}$ -inch pots, being afterwards plunged in the open, will when well established give a late crop of fruit this season from the middle of October onwards for a few weeks. Those who are growing the new French Strawberry St. Joseph will do well to secure the runners early and prove what this variety is capable of accomplishing. I have taken all the runners and intend to give it a thorough trial for late forcing. By its appearance it will only need $\frac{1}{2}$ -inch pots: it may, however, gain in vigour when rapid propagation is not resorted to for the necessary increase of stock.

AUTUMN RASPBERRIES, &c.—Give attention to these as may be needed. With me water has to be applied liberally, and mulching will soon have to be done. This, if done too early, might cause the growth to come away too strongly, and consequently not terminate in every case in flowers and afterwards fruit. The growths had better be thinned out where at all thick, sufficiently at any rate to admit light and air. This season I am trying what can be done to secure an autumn crop of Raspberries by cutting down a row each of Superlative and Hornet. At any rate, it is worth the trial if only a partial crop from these prolific kinds can be thus obtained from established plants. Other Raspberries newly planted should be well attended to for water and be mulched as well. Old plantations should be cleared of all old growths as soon as the present crop is all gathered, and the young canes be thinned out also.

THE BLACKBERRIES, represented by the cultivated forms, as the cut-leaved Bramble and the American kinds, are useful additions and worth attention when room can be given up to them. The former, in fact, is both ornamental and useful, being an acquisition to the wild garden or for the covering of rustic work, the forming of screens, &c., by reason of its very pretty foliage, with the knowledge that a crop of fruit will almost assuredly follow. Wilson Junior is an earlier variety than the cut-leaved, being almost over when the latter is ripe. A succession is thus secured. So far the Wineberry (*Rubus phoeniculus*) with me gives indications of fruiting very well, but like others of its class it evidently needs moisture. Of its utility more anon, but merely for ornament it is worth growing.

INSECT LIFE.—The trouble occasioned by aphides this season appears to be almost an universal complaint amongst gardeners. As far as I am concerned, I have had occasion to congratulate myself that strong doses were given in the winter to almost everything, and again some six weeks or two months back as occasion seemed to require it. Thus, for instance, the Cherries that were dressed with a strong solution of quassia extract about two months back have not been troubled much with the black fly, and these are dealt with as they appear. Upon Peaches and Nectarines

the green fly has now been conquered. It was late this season before daily syringings could be safely given. The paint-brush follows up the American blight still with extra strong doses, as no half measures will suffice. HORTUS.

ORCHARD AND FRUIT GARDEN.

APPLE CROP IN 1898.

THE peculiar weather experienced in this district during the month of May considerably marred the earlier favourable prospects of a fruitful year, for we had not only to contend with dull days and frequent showers, but on several occasions severe frost in addition. Many of the trees now present a pitiable condition, the leaves being covered with mildew and the trusses of flowers withered up as though they had been scalded. There is, however, some satisfaction in looking over the trees to find that the prospects are not quite so bad as at first sight appears, though a good many varieties are a total failure. With me the kind that seems to have suffered most is Cox's Orange Pippin, the most of the leaves, owing to the mildew, are now falling off. This is not only the case with old standards and bush trees that are well established, but also with young ones that should be full of vigour. Many others of the more tender varieties have suffered in like manner, though not to such a serious extent. The orchard here contains about 100 different kinds of Apples, and after going carefully over them I find there are many that have no fruit at all, while others have a fair sprinkling, and some have heavy crops. The first to bloom with me was the Irish Peach. The flowers having opened during favourable weather there is a good set, the trees being heavily laden with fruit. Worcester Pearmain is also good, likewise King of the Pippins, Rosemary Russet, Yellow Ingestrie, Golden Nonpareil, Adams' Pearmain, Mannington's Pearmain, Egrement Russet, Brownlee's Russet, and some others. Turning to the best of the cooking varieties, I find Lane's Prince Albert well to the fore, while Mere de Menage, Keswick Codlin, Warner's King, Ecklinville, Loddington, Seaton House, Domino, Frogmore Prolific, and some others are first-class. Many of the popular varieties have scarcely a fruit on them. It was not altogether the frost that played such havoc with the blossom, for the dull, damp weather was accountable for many of the flowers failing to set, the pollen seldom being dry, as there were only eleven fine days between the 26th of April and the 6th of June, though on one occasion the mercury fell to 25°. It would seem that some varieties are much more tender than others, as the various kinds growing side by side testify. Bramley's Seedling, for example, growing by the side of Ecklinville has scarcely a fruit on it, while there is not, as far as I can see, a single fruit of Gascoigne's Scarlet, Grenadier, Peasgood's Nonsuch, Baumann's Red Reinette, and many others so often seen on the exhibition table. Wellington is no doubt one of our best cooking apples, but with me the crop is very short this season, while the two most prolific are Irish Peach and King of the Pippins. For supplying the market, doubtless a few varieties that do well in the different localities are best, but for private establishments a collection of the most useful kinds is to be preferred, as there are far more chances of keeping up a continuous supply in this way than by putting all the eggs into one basket, as it were. In some seasons Kerry Pippin is one of the most prolific bearers, but this year with me the crop is short. There is also an advantage in planting trees irregularly, that is, instead of planting each variety by itself, mix them up as it were, then the possibility is that some trees will flower a little later than others, and thus bear a crop where those that bloomed earlier failed. There is also much to be said in favour of planting trees for shelter, both at the blooming period

and when the fruit is ripening.—H. C. P., *Buried Park, Sussex.*

The remarks of several correspondents from different parts of the country (widely apart) on the Apple crop—in some cases very favourable, in others quite the reverse lead to the inference that the crop is likely to be partial both as to locality and in different varieties. Personally I have not much to complain of, although the amount of fruit will be small in comparison with the extraordinary set. The fruit apparently set well, but on looking round bushes, pyramids, and young standards with the view to thinning, I find Nature has already performed the operation or is about to do so. It seems to me that some peculiar atmospheric influence must have been at work when certain varieties were on the point of setting, for whereas sorts as widely apart as Cox's Orange, Duchess of Oldenburgh, Adams' Pearmain, and Northern Greening are carrying capital crops, others as French Codlin, Blenheim, and Claygate Pearmain are very thin. Writing of Cox's Orange reminds me to ask if any correspondent can suggest anything to prevent birds attacking the fruit of this variety and also Ribston and Cornish Gilliflower. I am troubled both with tits and blackbirds, and the latter, as soon as the small fruit is over or they are kept away from it by netting, attack with an instinct that is akin to reason the choicest varieties. The trees are scattered about, and netting is consequently hardly practicable. I should be glad to know if coloured wool threaded about the trees, bright pieces of tin that will sway with the wind, or anything else have been tried, and, if so, with what result. I am both either to shoot birds or rob their nests, but in some seasons they are a great nuisance. All kinds of wall fruit are attacked unless netted, and last season they were helping themselves freely to Figs until these, too, had to be covered. Returning to Apples, one good point may be mentioned, and that is the absence of maggot, so we may reasonably suppose that the fruit obtained will be clean and sound. In looking through an old number of the Horticultural Society's Journal that contains an interesting paper on "New Fruits of Recent Introduction," I came across a suggestion that the Nanny Apple should always be included in a list of the best, and an answering remark by Mr. Bunyard that it seldom cropped. Possibly this applies, as in the case of the Blenheim, to young trees. I remember two very old standards at Petworth that cropped wonderfully well.—E. BURRELL, *Surrey.*

SCARCITY OF GOOSEBERRIES.

"WILTS" complains of having but a light crop of Gooseberries, and attributes this to the frost and cold winds. He also invites correspondence with the view of ascertaining how other counties have fared in the matter, and I most gladly oblige him with the necessary information regarding this portion of the county of Hereford, where Gooseberries are grown in large quantities both for private use and for market. Fortunately, we experienced but little frost during the time the bushes were in flower, but very cold winds were blowing more or less the whole of the time. I was afraid that this would affect the setting, but, contrary to expectation, heavy crops resulted—heavier, in fact, than any we have experienced for some years past. Under the influence of more genial weather the berries and bushes grew away quickly, and gathering was commenced by the middle of May. Since then gathering has been general, and large quantities of fruit have been despatched to the large towns. This has afforded a great deal of light labour to women and girls, and persons driving through the district have witnessed a busy scene daily. The crop in these gardens is equally as satisfactory in every respect as that in the plantations. The bushes of Whinham's Industry, also a great many of Warrington and Rough Red, have already been stripped—the former for cooking and the latter for preserving. These I grow by themselves and

away from those bushes on which the fruit is allowed to hang and ripen, the latter being in one block for the convenience of netting. To name any variety as bearing more heavily than another would be a difficult matter, so evenly are they all cropped, but I may mention that Whinham's Industry and Keepsake are the best early sorts. The bushes are making a great deal more growth than usual, and for this we are indebted to the heavy rains which fell in May and the early part of June. They are also clear both of aphid and caterpillars, which is a matter for congratulation. This immunity from attack I attribute to having applied lime for several years in succession to the surface of the soil under the bushes, by which means the pest seems to have become practically exterminated. A. W.

Stoke Edith Park.

GRAPE MADRESFIELD COURT.

WHEREVER finely-flavoured early and mid-season Grapes are in demand this variety should be planted. The long tapering bunches and distinct shape of the berries are well known, and well coloured examples are always appreciated. The foliage is deeply cut and takes on a fine colour in autumn, making it a good kind for supplying leaves for dishing up, and if a little growth is allowed to ramble by the front lights, these will be plentifully produced. It is peculiarly liable to cracking of the berries, this often following a careless mode of stopping the laterals and the removal of a lot of foliage and shoots at one time. This is bad practice for any variety, but if followed with Madresfield Court the cracking spoken of is almost sure to follow. Many Vines are allowed to make too much lateral growth, and although when this Grape is finishing it is all the better for a somewhat free lateral growth, at other times the principal leaves must not be crowded, nor must they be allowed to run wild. The laterals should be rubbed out of each joint below the bunch, the shoot stopped at the second or third joint beyond it, according to the distance the Vines are planted, and all resulting shoots kept rigidly pinched to the first leaf, not as soon as the latter can be seen, but before the shoots get at all woody.

After thinning and the fruit has begun to take its second swelling this Grape requires plenty of water, but when the colouring has fairly commenced it may easily be overdone. A moist atmosphere is more necessary at the earlier stages of colouring than some growers seem to think, and the sudden change from a moist to a very dry state of the atmosphere has done a great deal towards causing the wholesale cracking observable in bad cases. Harsh, dry air coming through a ventilator right against a bunch of thin-skinned Grapes will cause the side nearest the ventilator to crack badly, while the opposite side of the bunch will be perfect. I remember a very bad case of this in a well-known fruit-growing establishment in the south of England. The vineries were three-quarter spans facing south, and, of course, ventilated principally from that side at the apex of the roof, the ventilation being continuous. One very hot day I incautiously opened the small ventilators on the other side, one of which was just opposite a Madresfield with the fruit about half coloured. Next morning all the top bunches had gone as described, and this has always been a lesson to me on ventilation for this variety. Black Hamburgh, Buckland and other Grapes in the same house were uninjured. Later when the fruit is nearly finished there is less risk, and more air and a drier atmosphere will be gradually brought about. It is not a good keeping Grape so far as colour is concerned, the berries taking on a reddish tint after they are quite ripe. This makes it especially suitable for early houses that are cleared at once. A good mixture will be found in Muscat of Alexandria, Madresfield Court and Black Hamburgh, the first-named being planted at the sunniest end of the house, the others in rotation as named. The Madresfield

will be found the best grower of all and an ornamental Vine even in the earliest stages.

GROWER.

Cultivation of Vanilla.—The cultivation of Vanilla, according to the last bulletin from Kew Gardens, dates back to about twenty years ago, and is only now beginning to be thoroughly understood. The Mexican system of allowing the vines to grow under trees nearly wild is almost universally adopted at present, and is a decided improvement on the old system of training the vine on artificial supports. Nothing pays better than Vanilla. Its production costs the planter Rs3 per pound, and as prices vary from Rs8 to Rs16 the pound, a net profit of from Rs5 to Rs13 is the result. This year the average price was Rs15 the pound. The yield may be taken to be 200lb. an acre. Taking, therefore, an average of Rs10, an acre of Vanilla should produce Rs2000. Most of the land in Seychelles is in the hands of private owners, and it is difficult to estimate its cost, but it may be taken that land can be bought at from Rs100 to Rs200 the acre. It has been stated that landowners are reluctant to part with their land, but not much difficulty need be apprehended on this score provided that purchasers are prepared to pay ready money. There is some land belonging to the Government well adapted for Vanilla cultivation which can be leased for periods varying from nine to twenty-one years. Seychelles is, unfortunately, almost a *terra incognita*, but there is little doubt that if the scores of young Englishmen who leave the mother country year after year for other lands knew of it, they would give the preference to an English colony which offers advantages not to be met with elsewhere for the investment of small capital, say £1000.

TREES AND SHRUBS.

CLIMBING HONEYSUCKLES.

(LONICERAS.)

THERE are few hardy climbers that possess so great a charm as the Honeysuckles. Our native species, *L. Periclymenum*, the common Honeysuckle or Woodbine, is, on the whole, perhaps the best. At this season of the year it is one of the greatest of the many delights of an English country lane, not only because of the beauty and exquisite fragrance of its flowers, but also for the many poetical associations that cluster round the name. Most of the species mentioned in the following notes are of the same type of growth. With the exception of *L. japonicum*, they belong to the section of *Lonicera* known as "Caprifolium," which can be roughly distinguished by the flowers generally coming in whorls at the ends of the shoots, and by their climbing habit. Every one of them is worth growing, and they are, collectively, of greater value in the garden than the bush Honeysuckles, which constitute the section "Xylosteum," and of which the commonest example is furnished by *L. tataricum*. They are easily accommodated in gardens, preferring a rich soil of an open quality, plenty of moisture, and a position fully exposed to the sun. In the open border they can be trained up rough posts of Oak or Elm, which are all the better if rough snags a foot or so long have been left on them. Perhaps they are most charming when grown as Nature suggests—that is, when allowed to clamber over other shrubs and small trees. The American species of the glauca type, however, are not so suitable for this method as our own native species, being of shorter, sturdier habit and having thicker foliage. The accompanying engraving shows very delightfully the natural style of growth. On the other hand, a more luxuriant growth and finer flowers are obtained where the plants are grown away

from other things, and where their roots have their own domain, and the upper growth full exposure to sunlight and air. This season we have been very much troubled with aphides, and it has been a difficult matter to keep them down. A solution of tobacco and soft soap syringed over the plants in the evening is the best remedy.

LONICERA CAPRIFOLIUM.—This (sometimes called the perfoliate Woodbine) is one of our English Honeysuckles, and is closely allied to the common one, *L. Periclymenum*. It is, however, very readily distinguished from that species by the smooth, more glaucous leaves and by the terminal pairs on the flowering shoots being united all round the stem so as to look like a single leaf. The flowers are borne in the axils of these connate leaves. Each flower is $1\frac{1}{2}$ inches long, pale yellow, suffused with pink. The berries are oval and scarlet or orange-coloured. Some authorities have had doubts as to whether this is a real native of Britain, or whether it is simply naturalised, but if it is truly indigenous, Cambridge and Essex are the only counties in which it is so. It flowers two or three weeks in advance of the common Honeysuckle, and climbs as much as 15 feet or 20 feet high. It is a beautiful shrub, although its flowers, perhaps, are scarcely so fragrant as those of the common Honeysuckle.

L. ETRUSCA (GIGANTEA).—Under the name of *Lonicera gigantea* a valuable Honeysuckle has recently come prominently into notice. The plant so named is a form, perhaps finer and hardier, of the old *L. etrusca*. It is made synonymous with that species by Mr. Nicholson. Its strong vigorous shoots bear large oblong leaves, noteworthy because of their covering of dense hairs. The stems are reddish purple, and bear at and near the tips large showy, dense clusters of flowers. These flowers are at first yellowish white, but become a deeper and richer yellow as they get older; they have a sweet, pleasant perfume. To those who take an interest in the climbing Honeysuckles this vigorous and beautiful species may well be recommended. It is a native of Southern Europe.

L. IMPLEXA.—Although this species was introduced to Britain as long ago as 1772, and is quite hardy near London, it is not a well-known Honeysuckle even yet. It is a native of South Europe and the Balearic Islands. Unlike the preceding species (*L. etrusca*), its stems and leaves are quite devoid of woolly covering. The latter are 1 inch to $1\frac{1}{2}$ inches long, very glaucous beneath, without stalks, the lower part of the blades of each pair often overlapping. The stems are of a purplish hue, and bear the flowers at the end of the shoots and from the axils of the uppermost leaves. The flowers are purple outside and white within on first opening, afterwards changing to yellow. It is said to grow as much as 15 feet in height, but I have not seen it more than about 8 feet. It is a pretty plant, distinct because of its small leaves and closer growth.

L. PERICLYMENUM.—There is no plant more characteristic of our hedgerows and thickets, or adds more to their beauty and charm, than the common Honeysuckle or Woodbine. It flowers from June to August and often later, and during that time is one of the most beautiful as well as one of the most exquisitely fragrant of hardy shrubs. It is in the cool and dewy mornings and evenings that its fragrance is richest. This plant and *L. Caprifolium* are very similar, but its leaves are often downy and are not so glaucous, nor do the terminal ones become united (connate) as they do in *L. Caprifolium*. The flowers are borne in terminal clusters and are deep red outside, yellowish within. They are followed by crimson berries. It is a variable plant, and the following are the more noteworthy forms:—

L. P. VAR. BELGICA.—This has smooth, purplish stems, and is of sturdier habit than the type. It is often called the Dutch Honeysuckle.

L. P. VAR. QUERCIFOLIA (the Oak-leaved Honeysuckle) has leaves shaped like those of an Oak. It is a native of Britain.

L. P. VAR. SEROTINA.—This flowers later than the others, and its blossoms appear more simultaneously, thus producing a finer show.

L. JAPONICA.—This species may be taken as the type of a group of Honeysuckles that have come to us from China and Japan and known in gardens under such names as *Halleana*, *confusa*, *chinensis*, &c. Slight differences might be found, but they are all near enough to come under the one species. They are evergreen and grow very luxuriantly in good soil, coming into flower towards the end of June or the beginning of July and continuing for a couple of months. The blossoms are borne in pairs on short axillary branches, and are white at first, changing to yellow with age. They have a most charming fragrance, suggesting that of the common Honeysuckle with that of the Cowslip mingled. The broadly ovate leaves are pointed, bright green, and vary from 1 inch to 3 inches in length. In some of the forms there is a tendency towards the leaves becoming pinnatifid or sinuately lobed.

An arch of Honeysuckle.

The most distinct of the varieties is the one named

L. J. VAR. FLEXUOSA.—This has dark red stems and dark green leaves, the under surface of which, more particularly on the veins, is also red. The flowers are pale red outside, white within.

L. J. VAR. HALLEANA has flowers like those of the ordinary *japonica* in being white and afterwards changing to yellow, but it flowers during a longer period. All these varieties can be grown up single stakes, or on three stakes made to form a pyramid; they then form dense evergreen masses and are useful as bushes, for they need not be allowed to grow more than 5 feet or so high unless desired.

L. J. VAR. AUREO-RETICULATA is a variegated form of this Honeysuckle—known also as *L. brachypoda reticulata*—and is one of the handsomest golden variegated plants of its kind we have. The leaves are smaller than in *L. japonica*, being about 1 inch long, broadly ovate, with the mid-rib and veins picked out in bright golden

yellow. It loses most of its beauty in winter, but during the summer time is very bright. I find it very useful as a covering for old tree roots half buried in the ground.

THE AMERICAN SPECIES.

L. FLAVA.—The first mention of this species in a botanical work was in 1802, and shortly after this date it was sent to England by John Fraser, a well-known collector of American plants in the early years of the century. He discovered it on the summit of Paris Mountain, in South Carolina, and curiously enough it was never again collected wild till within the present decade, when it was again discovered on the same site, and subsequently in one or two more isolated localities. The few plants in cultivation are all descendants of Fraser's plants, and it is, either in a wild or cultivated state, one of the very rarest of North American shrubs. Its climbing stems are set with thin, slightly glaucous leaves, the upper pairs of which are, as in *L. Caprifolium*, connate. The flowers appear in short, terminal clusters, and are bright yellow changing to orange, and the slender tubular part of the corolla is 1 inch to $1\frac{1}{2}$ inches long. This Honeysuckle has been much confounded with *L. Sullivanti*, but it is a more beautiful plant.

L. GLAUCA.—This is a very handsome species and one of the very hardiest of the American Honeysuckles. In a wild state it penetrates far to the north of Eastern America, and is said to reach even the shores of Hudson's Bay, extending thence right through Canada, New England, &c., as far to the south as the mountains of Carolina. Its stems rarely grow more than 6 feet to 7 feet high, and its leaves are a pale glaucous green. On the flowering shoots the leaves are without stalks and the uppermost ones are united as in our native *L. Caprifolium*. The flowers are of a greenish yellow tinged with purple, and are borne in close whorls at the ends of the shoots during June and July.

L. HIRUTA.—This is another of the climbing Honeysuckles of the Eastern United States. It is a tall, twining plant, differing from *flava*, *glauca*, and *Sullivanti* in the absence of a glaucous bloom on the leaves; they are green and covered with a soft down. The flowers are orange-yellow, and the corolla, the tube of which is half an inch long, is covered on the outside with a viscid pubescence, whilst the throat is hairy. It is a hardy plant, generally found wild on rocky banks in Canada and New England southwards to Michigan and Pennsylvania. Although it has hitherto been neglected in this country, it is one of the handsomest of the American Honeysuckles.

L. SEMPERVIRENS (Trumpet Honeysuckle).—Of all the Honeysuckles this has the brightest coloured flowers, and when seen at its best is, perhaps, the most beautiful. But, on the other hand, the flowers have no fragrance, and the plant itself can only be satisfactorily grown out of doors against a wall or in specially mild districts. Its leaves are naturally evergreen, obovate, bright green above, blue-white beneath, the lower ones stalked, but the upper pairs united round the stem. The flowers are borne at the tips in a series of superposed whorls, the long trumpet-

shaped corolla being of a brilliant scarlet, tinged with rose outside and with yellow in the throat. As a climber for the cool greenhouse this Honey-suckle proves very valuable, flowering continuously over a long season. A good plant is now in bloom in the greenhouse (No. 4) at Kew. The Trumpet Honeysuckle is a native of the South-East United States.

L. SULLIVANTI.—There has been a good deal of confusion between this species and *L. flava*, but it is not so distinctly a climber and its stems more bushy and dwarfer. Its leaves are very glaucous, thick in texture, 2 inches to 4 inches long, and ovate or oblong, the upper pairs joined together. The flowers are borne in whorls near the tips of the shoots and are pale yellow; the tubular part of the corolla is scarcely half an inch long, and there is a prominent chin towards the base, which affords a means of distinguishing this species from its close allies. The plant is conspicuous by its covering of white glaucous bloom, but on the whole it is less beautiful than *flava*. It is widely distributed in the Eastern United States, and was first brought into notice by the Mr. W. S. Sullivan after whom it is named. The fruit is handsome, the berries being bright red and borne in large clusters.

W. J. B.

THE EFFECT OF COLOUR.

It would be difficult to imagine a garden without colour, and it is when flowers fall, tints fade, and leaves rustle mournfully to the ground that the garden becomes a cheerless place. Even then, however, Nature provides for herself and us in the production of evergreens in varying shades, that keep up a ray of brightness the whole year round and check to some extent the air of depression that will have way. In the early summer, however, there is a different tale to tell. The garden is aglow with colour, so bright and profuse, and, where judiciously distributed, so harmoniously blended, that to match the effects of Dame Nature the brush of the most talented artist might be wielded in vain. Leafy June might also be called the month of bloom, for it is now that flowering trees and shrubs are full of beauty, and, no matter where you look, some bright mass of colour meets the eye.

From the sentimental, thoughts turn to the practical, and the present beauty of flowering trees and shrubs suggests many things to the thoughtful mind. In the first place there is the usefulness of such trees for garden adornment. To name them there is no necessity to go into minute details, but confine ourselves to the Lilacs, Hawthorns, Laburnums, Cytisus, Rhododendrons, Guelder Roses, Syringas, and other well-known flowers. These may be divided again into species and varieties to suit individual tastes, but, speaking generally, there is diversity enough to make any garden gay in the early summer months. One standing want generally noticed in what is known as the shrubby portion of gardens is that of colour. Masses of sombre foliage become sally monotonous to the eye that naturally demands variety, and if it is only a solitary touch of something bright it is a relief. The effect in many established gardens has been made or marred by the planter years ago, and the charms of many a landscape are obliterated by the want of something bright and cheerful to break the monotony of the surroundings.

Only recently when visiting a garden of large dimensions I noticed this. There were fine banks of Bay Laurels, specimens of Portugal Laurel, giant trees of Hemlock Spruce, Cedar of Lebanon, Wellingtonia, Arbor-vite, and other conifer. They were all fine specimens, qualified to raise the enthusiasm of any tree lover, but to the lover of colour there

was something wanting. There was no escape from the sameness of the varying shades of green, nothing to break the contrast of the pale green Laurels and the sombre Pines. I say nothing, but here I commit myself, for there was one solitary Laburnum rising from a groundwork of Laurels, and apparently unconscious of its conspicuousness. How it came there I know not, but from all appearances it came of its own free will, and from a tiny self-raised seedling grew into a tree. It was just prominent enough to give one an idea of how the landscape might have been improved by the presence of other flowering trees. There are always lessons to be learnt and trees and shrubs to be planted, and the moral is, not to pay too much attention to foliage, but to remember the flower. The picturesque in landscape is that in which light and shade with harmony in colour lend themselves in the formation of a happy blend, without which there is a dulness on the one hand or a vulgar multiplicity of colours on the other.

My mind's eye pictures a garden, perhaps well known to many readers of these columns, namely, that of Alton Towers, in Staffordshire. It is beautiful at all times, but more particularly so in early June when the many flowering trees and shrubs are at their best. The garden is situated in a natural valley, and the banks on either side are clothed with Rhododendrons interspersed with serpentine walks, patches of green turf, and specimen trees. Most of the Rhododendrons are the common *R. ponticum*, but here and there are brighter coloured hybrids recently planted. Down the centre is a cascade, where water tumbles from rock to rock, forms itself into a succession of pools, and finally loses itself in the valley below. Both sides of the waterfall are clothed with massive Rhododendrons, and over the cascade droop golden Laburnums and crimson Thorns. White and purple Lilacs are dotted here and there, and Guelder Roses and Magnolia conspicua show themselves to advantage against the dark green of the Hemlock Spruce. Altogether the effect is charming, and never more so than in the evening when viewed from a high position where the whole panorama lies before you.

The common Rhododendron grows freely in the light soil resting on sandstone, and groups of this shrub have developed themselves into dense thickets which clothe the sides of the valley with a profusion of flower, which is shown to the fullest advantage in the evening sunlight. Here and there are drooping masses of yellow Laburnum flowers and white and crimson Thorns, purple and white Lilacs, and many other flowering trees and shrubs, each of which helps in making contrasts that collectively form a happy blend. The varying shades of foliage are no less pleasing. Here is a fine specimen of Copper Beech, there a tree of the cut-leaved variety with pale green foliage against a background of dark Hemlock Spruce. The early growth of the Pines is almost silvery in the fading sunshine, and at different points recently planted trees of Japanese Maple make themselves conspicuous. Added to all this there is a stillness unbroken except for the song of feathered life and the music of rippling water. The scene is beautiful without being grand and gives to one an impression of rest and peace such as a garden, to be a garden in the true sense, ought to impart.

I give this imperfect sketch to illustrate the advantage gained by the presence of flowers in the shrubby portion of gardens. There is a medium, of course, and one frequently sees instances, particularly in the surroundings of

suburban dwellings, where foliage would be a relief to tone down the gaudy glare of unharmonising colour. The ideal in landscape gardening is to dispense as much as possible with the artificial, and in copying Nature to do it thoroughly, for even in the wildness of a hedge-row or woodland it is not all leafage, but a happy mixture of colour supplied by simple flowers, in the absence of which there would be something wanting. G. H. H.

COTONEASTER PANNOSA (FRANCH.).

This new species of Cotoneaster was introduced by the Museum of Natural History at Paris about the beginning of 1888. Professor Max Cornu received some seeds of it from the Abbé Delavay, a missionary in Yunnan. The seeds were labelled "Hu-Chan-meu fruit rouge," the first name being that of the locality in which the seeds were gathered. Sown on May 28, 1888, they produced a sufficient number of specimens to permit of their being sent out in 1890. The plant appears in the Museum's catalogue of living plants offered for exchange to other botanic gardens in 1890 and 1892 under the name of Cotoneaster sp. (Yunnan). The plant flowered and bore fruit for the first time in the gardens of the Museum in 1897, both flowers and fruit showing themselves in profusion, which permitted of its being placed for distribution purposes in the "Index Seminum" for the end of 1897. It was presented by Professor Cornu as a new plant to the National Society of Horticulture of France in the month of October, 1897. Such in a few words is the history of its introduction.

C. pannosa is easily distinguished from other species. From a decorative point of view it is to be recommended for its persistent foliage, the underside of the leaf, of a beautiful silvery white, being in marked contrast with the deep and lustrous green of the upper surface side, and for its abundant flowers, but especially its brilliantly coloured fruit. It is, we think, a real acquisition and a fine addition to the series of shrubs which during the cheerless season of winter help to enliven our gardens with their fruit, which for brilliancy is equal to that of the richest blooms. We believe *C. pannosa* to be hardy in the Paris climate. The trials to which it has been submitted at the Museum were satisfactory on this point. It must be added, however, that specimens placed outdoors have not so far withstood the severe winters. The altitude of 9000 feet or so, given by the Abbé Delavay to be that at which the plant grows spontaneously, offers no certain criterion in this respect. Alpine plants, which in their natural habitats easily withstand considerable falls of temperature, protected as they are during the winter by a thick blanket of snow, in the plains require shelter, where, nevertheless, the rigours of the inclement seasons are much less severe, but where the snow is often wanting and alternations of frost and thaw are frequent. A regards soil, *C. pannosa* appears to be very easy to please. It is easily increased by seed and also by cuttings during the summer.—L. HENRY, in *Le Jardin*.

Manure cards on show exhibits.—My note on this subject, on the action of the Royal Horticultural Society, which appeared on page 540, brought me an interesting communication from a well-known Chrysanthemum grower, in which he mentioned that at one of the great shows of the N. C. S. he found on the second morning of the show that two large cards relating to a certain expensive and well-puffed manure had been placed on his exhibits, intimating that these flowers had been grown with the manure in question. The exhibitor removed one card, and on the other wrote prominently the word "not" over "grown," and placed it in a prominent position. The result might be readily anticipated, for no sooner was the exhibitor's back turned than the obnoxious card was removed. I marvel that

officials and committees of shows permit this sort of thing. The exhibitor in question states that he had never used this manure in his life.—A. D.

STOVE AND GREENHOUSE.

RICHARDIA ELLIOTTIANA ROSSI.

WITHIN the last decade we have had two or three very distinct forms of *Richardia* (*Calla*), remarkable for their rich golden-coloured spathes, introduced into cultivation, and from their distinct character and extremely showy blossoms they quickly became popular. The first of this class was *Richardia Elliottiana*, which attracted a deal of attention when it was first exhibited in bloom. It proved to be a good seed-producer, the result being that it was soon to be obtained at a moderate price. The variety *Rossi*, which has been brought prominently forward during the present year, was first flowered by Mr. Donald Ross, of Capetown, who stated that the plants came from a different locality to that in which *R. Elliottiana* and *R. Pentlandi* were discovered, and that they were in every respect an improvement upon them. A great number of dormant tubers of this variety were disposed of in the London sale rooms in the early part of the present year, but up to now none of mine have flowered. The appearance of the foliage suggests that it is a rather small-growing variety of *R. Elliottiana*, and produces offsets more freely than that does—indeed, that it is inclined to form quite a tuft, but these features may disappear with cultivation, the conditions under which it is grown being in every way so different. An illustration of it, which was to be seen when it was offered for sale, suggested that the flower-stems were shorter than those of the typical *R. Elliottiana*, whose flowers stand well above the foliage, while those of *Rossi* were scarcely higher than the leaves. Though anticipating with much interest the flowering of this particular variety, I am afraid that mine will not bloom during the present season.

Owing to the interest centred around these golden-flowered *Richardias*, many districts have been scoured in the search for them, and large numbers of imported tubers have made their appearance in this country. I have grown a considerable number of them, but never obtained in this way the true *R. Elliottiana* as flowered at first by Captain Elliott, after whom it was named. The prominent characteristics of this form are the rounded blade of the leaf and the manner in which the lower part of the stem is mottled with brown in the way of an *Albocasia*. The foliage of *Rossi* is of the same character, but at present smaller than that of the typical *R. Elliottiana*. The majority of the imported tubers consists of *R. Pentlandi*, or of some forms closely approaching it. In *R. Pentlandi* the leaves are more pointed and with less substance than in *R. Elliottiana*, while they are of a uniform deep green. The flowers, too, though of a rich golden yellow, are marked at the base in the interior with deep blackish purple, which is wanting, or almost so, in *R. Elliottiana*. This purplish tinge, however, varies to a certain extent in different individuals. In some importations there is a fair sprinkling of a form which is an exact counterpart of *R. Pentlandi*, except that the leaves are marked with translucent whitish spots, as in *R. Elliottiana*. This is occasionally met with as *R. Pentlandi maculata*. I recently had a plant of this brought under my notice in which the spathe was of a

sulphur tint instead of the deep golden hue common to this form. In the cultivation of these *Richardias* it should be borne in mind that they are natives of the region considerably to the north of the Cape, and consequently require a higher temperature than the common *R. africana* to grow them successfully. Thus, though one often hears of them spoken of as *Arum* Lilies with yellow flowers, the points of difference are most marked, for these golden forms require the temperature of an intermediate house (at least during the spring of the year) to grow them successfully, while they formed a flattened, roundish tuber and pass the winter in a totally dormant state. They need to be shaken entirely clear of the old soil and started afresh in new compost about February.

H. P.

Crinum Moorei variegatum.—Most of the *Crinums* are remarkable for their showy, if somewhat short-lived, blossoms, but in this form the foliage is decidedly handsome, being marked in a longitudinal manner with stripes of creamy

Richardia Elliottiana Rossi. Engraved for THE GARDEN from a photograph sent by M. Louis Van Houtte, Ghent, Belgium.

yellow and different shades of yellowish green, which vary a good deal in width. In nearly all the leaves the coloured portion preponderates over the normal green tint. The flowers of the variegated variety are as in the type, but the foliage loses its freshness before the blossoms expand. This variegated form of *Crinum Moorei* is at present not much known, but as this species produces offsets freely it will doubtless in time be more generally met with.—H. P.

Double Pelargonium Charbon Ardent.—We have not many double-flowered *Pelargoniums* of an orange-scarlet shade, and some of the limited number are rather apt to run up tall, which cannot, however, be said of this variety, for it is, as far as my experience extends, one of the very best of that tint. Though the flowers of *Charbon Ardent* are orange-scarlet in colour, they are of a peculiar and striking shade. It is of good dwarf habit and very free flowering, so that it is equally valuable as a pot plant or for the production of cut blooms. Its origin I cannot give, and the name rarely occurs in any catalogues. Perhaps it is a comparatively old kind rescued from oblivion, as happened in the case of the now popular *F. P. Raspail*, which was sent

out about ten years before its merits were recognised.—H. P.

Malmaison Carnations.—Each year sees many additions to the list of good *Malmaison Carnations*, and most of the newer ones do not appear as yet to have contracted the disease which is almost always to be seen in some degree in the older forms. *R. H. Measures* is a very fine variety with scarlet-cerise flowers shaded white, and practically a non-burster, with a good constitution. *Princess May* is another finely-formed flower of a deep rosy red colour. *Mme. Adeline Patti* bears a very strong likeness to the old blush variety, but the flowers are larger and fuller than we are accustomed to see in this old favourite. Two fine scarlets are *Lord Rosebery* and *Prime Minister*, in both of which the form is distinctly good.—J. C. T.

Streptocarpus Wendlandi.—This *Streptocarpus* when grown singly in pots is very ungainly-looking and lop-sided, owing to the enormous development of the single leaf. Not liking its appearance in this form, I made up this year two huge specimens in deep pans, and the result is excellent. The plants have forty or fifty spikes now showing and the forwardest of these in full flower, while the specimens are as shapely as anyone could wish. The method adopted in making up the pans was to put an outer ring of plants with the leaves pointing outwards and filling up inside in the same way, so that the leaves overlapped in an outward direction all through. The soil used contains a fair quantity of decayed cow manure, as I find that all the *Streptocarpi* like this and continue to flower longer than they would without manure. I expect these plants to flower continuously from this time till the end of September, and to produce a great number of flowers during the season. The tall scapes of *S. Wendlandi* are very useful and lasting in a cut state. Its foliage, as in the case of that of the hybrid forms, must be protected from direct sunlight, as it is very susceptible to scalding.—J. C. T.

Fuchsia General Roberts.—The list of garden varieties of the *Fuchsia* is now almost endless, and among these in cultivation are many forms, some being particularly useful for one purpose and some for another. Of late, attention has been directed to the great value of the *Fuchsia* for clothing the roofs of greenhouses or similar uses, and for this the variety above mentioned, *General Roberts* is one of the very best. The style of growth is somewhat lax, and this, combined with the long peduncles and great profusion of large, showy blossoms, is greatly in its favour. The flowers of this variety are dark, and where a light-coloured comparison is desired, the old market variety *Mrs. Marshall* is good.

A bright red flower with the sepals and petals of almost the same colour is *Monarch*, whose individual blossoms are very large and freely borne, while the habit of the plant also fits it for clothing roofs. Of varieties with white corollas, a very old kind, *Alexandra*, is one of the best, but it is not easy to obtain. Failing this, *Flocon de Neige* is very good. To these four may, if required, be added *F. penduliflora*, one of the original species, which has large clusters of bright showy blossoms, and *F. gracilis*.—H. P.

Zonal Pelargoniums with spotted flowers.—Some three years ago *M. Lemoine*, of Nancy, sent out among other *Pelargoniums* a variety (*Alliancee*) which was quite a break away from any existing forms. It is very free-flowering and the blush-coloured flowers of good shape, but the great feature is that the three lower petals are thickly, and the two upper ones more sparingly, freckled with small, clearly-defined dots of purplish crimson. This dotting is far more profuse towards the centre of the flower than at the outside. A variety with flowers so marked attracted, of course, a good deal of attention, and another peculiarity is that it is more or less prolific, for when the flowers on a large truss fade, small

clusters are often pushed out therefrom, these in turn bearing a few blossoms. A break once obtained, other varieties followed in the same way, and one distributed last year (*Orestes*) has the dotting more pronounced than in the older kind. The ground colour of this is a kind of lilac-pink and the dots purple. Other varieties of this class distributed by continental raisers during the present year that have up to now flowered with me are *Daumier*, very thickly freckled with red on a lilac-pink ground; *Ciel Etoile*, pale whitish lilac, dotted with carmine; and *Pleiades*, rosy lilac, with carmine dots. There is at least one double-flowered form in the same way, viz., *Voûte Celeste*, in which both the clusters and individual flowers are large, the latter being of a blush tint plentifully sprinkled with bright crimson. It is quite a break away from the ordinary double-flowered forms, and so are some of the attractive coloured varieties of the *Mme. Jules Chrétien* class, of which there are now several with double blossoms.—H. P.

SOCIETIES AND EXHIBITIONS.

NATIONAL VIOLA SOCIETY.

JULY 2.

THE display made by the supporters of this society at the Crystal Palace on the above date was disappointing. The competition was not so keen as the executive desired, but the heavy rainfall of the early morning no doubt to a large extent was responsible for this. It was a very hasty arrangement to fix the date and place for the show, in conjunction with those of the National Rose Society's display. Scotland, the west of England and the south were represented at the exhibition, and it was interesting to compare the products of one with the other. The neat, though formal arrangement of the Tufted Pansies in sprays, with their own foliage, was effective, and this year the executive offered prizes for blooms arranged without wire in specimen glasses. This latter arrangement was appreciated by some, who find making a spray a long and tiresome occupation, while in a comparatively short time quite a large number of glasses may be filled with these interesting and pretty blossoms. Tufted Pansies made by far the largest display, and conspicuous among them were the increasingly popular rayless types of the flower. Miniature Tufted Pansies were represented by one board of blossoms only, and as these are so very pretty and interesting, it is a pity more were not forthcoming. The flowers kept very well during the day, notwithstanding the fact that the heat was very trying during the afternoon.

In the open classes the principal competition was for forty-eight sprays of Tufted Pansies, distinct, nine blooms in each spray. The gold medal for this display was well won by Mr. William Sydenham, Tamworth, Staffordshire, for a nice, bright and representative lot of blossoms. Among the best of his sprays were *Kitty Hay*, one of the best of the deep yellow rayless self; *William Tell*, a creamy white flower with a rich yellow eye and rayless; *Lemon Queen*, Masterpiece, a pure white self; *Queenie*, a medium-sized flower rather like *Border Witch*; *Commander*, a large rich purple self; *Councillor W. Waters*, a bright bluish purple self; *John Quarton*, a deep mauve and very effective; *Cottage Maid*, deep bluish purple and light lavender markings; *Lizzie Paul*, rich yellow rayed self; *Mary Scott*, one of the loveliest of blue-tinted white rayless self; *Ophelia*, a new colour of deep heliotrope blue, large and rayless; *Florizel*, a pretty blush-lilac rayless self; *Magnificent*, a good rayed blue self; *Stephen*, a large rich yellow rayed self; and *Pembroke*, the best of the rayless yellow selfs, besides many other choice sorts. Second prize was well merited by Messrs. Isaac House and Son, Bristol, for a wonderfully fresh display, and including a goodly number of both old and new sorts. Conspicuous among them were *Border Witch*, a

pretty shaded and edged blue on a white ground; *Craigi*, lower petals purplish crimson, upper petals shaded lavender; *Christiana*, cream self, with large yellow eye; *Duchess of Albany*, a bluish rose; *A. J. Rowberry*, rich rayless yellow self; *Magie*, a beautiful rich rosy crimson; and *Stobhill Gem*, lower petal rich deep violet, upper petals bluish white. Messrs. I. House and Son were also placed first for forty-eight sprays of fancy Pansies, distinct, six blooms in each spray, thereby securing the gold medal. These made a bold display, especially so when contrasted with the refined and delicate colouring as represented by the Tufted Pansies in other classes. The most notable varieties in this class were *Col. M. R. G. Buchanan*, *Jas. Stewart*, *Mrs. W. Steele*, *Betsy Kelly*, *Jas. J. Irvine*, *D. Russell*, *D. G. McKay*, *Bernard Doulton*, *The Baron*, *Annie Ross* (very fine), *W. H. Clark*, *John Jackson*, *Beauty*, and others. For twenty-four fancy Pansies, distinct, there was only one competitor, Mr. M. Campbell, High Blantyre, near Glasgow, being placed first with a very nice, even, and fresh lot of flowers. Most conspicuous were *Annie Ross* (a very fine sort), *W. Steele*, *Marmion* (excellent), *D. G. McKay*, *Sir J. Watson*, *Mrs. R. Stewart*, *W. H. Clark*, *J. Menzies*, and *Mrs. N. McKay*. Mr. Campbell also secured premier honours for twelve fancy Pansies, distinct, *Col. M. R. G. Buchanan*, *Mrs. W. Steele*, *Bernard Doulton*, and *Mrs. R. Stewart* being in fine form. Messrs. I. House and Son were second with smaller and less even blooms. The competition was keen in the class for twenty-four sprays of Tufted Pansies, Mr. M. Campbell being well to the fore with a fresh and clean lot of flowers. These were well and neatly set up, and were remarkably fresh after their long journey from the north. His best were *Magie*, *Liz. Barron* (large crimson-purple), *Dr. Stokes* (a crimson and rose-striped sort), *Duchess of York* (white rayed self), *Princess Ida* (pale rosy heliotrope), *Nellie* (cream-white), *Butterfly* (margined rose on white ground), *Lord Salisbury* (rather coarse, primrose, heavily rayed), *Lizzie Paul* (rayed yellow self), *A. J. Rowberry* and *Dorothy* (a lovely pale blue self rayless). Second prize was won by Messrs. J. Cheal and Son, Lawfield Nurseries, Crawley, Sussex, with a nice lot of sprays. *Duchess of Fife*, *William Niel* (pale rose), *Sweet Lavender* (lavender-blue self rayless), *Bridesmaid* (pale yellow self), *Florizel* and *Norah May* (blush self) were the most noticeable. For twelve sprays rayless Tufted Pansies, distinct, Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, was a good first, with this type of the flower well represented. The best sprays were *Devonshire Cream* (creamy white), *Nellie*, *White Empress* (large white self, yellow eye), *Florizel*, *Rosea Pallida* (pale blush rose), *Mary Scott*, a bright yellow seedling, *Christiana*, *Sir Robt. Peel* (citron-yellow, with an orange eye), and *Britannia* (a splendid imperial blue self). Second position was secured by Messrs. I. House and Son with much smaller, though pretty flowers. *Blush Queen*, *Border Witch* and *Cooper O'Fogo* were their best. For twelve saucers of blooms, distinct varieties, arranged in moss and without wires, the saucers not to exceed 6 inches in diameter, Mr. Campbell was again successful with a neat arrangement, and with varieties already enumerated. Messrs. I. House and Son followed with a smaller, but evenly arranged exhibit. A class for twenty-four varieties, nine blooms of each, arranged in specimen glasses with *Viola* foliage, neither blooms nor foliage wired, was also an interesting experiment, and made a fine contribution to the display. Messrs. I. House and Son were again to the fore with a neat and pleasing arrangement and with a nice assortment of colours, *Mrs. C. Lowe*, *Ryhall*, *Stamford*, being second, using rather more foliage than was necessary, but this was a nice exhibit all the same. For a special prize offered by Mr. B. G. Sinclair for six vases of Tufted Pansies, nine blooms in each, and arranged with any kind of foliage, Mr. D. B. Crane was a good first. His choice of light green fronds of *Maiden-hair Fern* and *Panicum variegatum*, and selection of colours

to associate pleasingly with this, assisted materially to place him in the coveted position. Messrs. I. House and Son were second with a nice display.

In the amateur classes the competition was not so good as usual, and was a constant source of comment. For twelve sprays Tufted Pansies, distinct, Mr. D. B. Crane was first with a fine lot of fresh flowers—*Mary Scott*, *Magie*, *Duchess of Teck*, a recent sport from *Duchess of Fife*, the edging being of a much deeper blue; *Pembroke*, *Mrs. C. F. Gordon*, a grand improvement on *Countess of Kintore*, a fine yellow seedling rayed; *Duchess of Fife*, *Endymion*, a pale yellow rayed self; *Isa Fergusson*, blue-black lower petals, upper petals deep lavender, and *White Empress*. For six sprays, distinct, Mr. Leonard Brown, The Cottage, Seven Arches, Brentwood, was first with a capital stand of flowers, *Stephen*, *Goldfinch*, *Magnificent*, *Mrs. C. F. Gordon*, and *Mrs. Wm. Greenwood* being beautifully represented. For the novices, six sprays, three blooms in each, *Major-General Gillespie*, *Sydenham*, showed a pretty lot of flowers for a beginner, and was deservedly placed first. For six sprays rayless Tufted Pansies, Mr. L. Brown was first, showing *Pembroke*, *A. J. Rowberry*, *William Tell*, *Lucy Franklin*, *Florizel*, and *Blanche* (a pure white self), second prize falling to Mr. D. B. Crane, who followed very closely. In the class for six sprays miniature sorts, Mr. Brown was again first, showing charming sprays of *Blue Bell*, *Old Gold*, *Mabel*, *Bessie*, *Canary Bird*, and *Violetta*, admirably illustrating the charming characteristics of these valuable sorts. Mr. B. G. Sinclair, Highgate Road, N.W., was placed first for six saucers of Tufted Pansies, and these were filled with nice, fresh and clean blooms of *Lady Isabel*, *Mrs. C. F. Gordon*, and *Norah May* among others. For nine varieties arranged in specimen glasses, *Dr. Shackleton*, *Aberdeen House*, *West Hill*, *Sydenham*, secured leading position with a capital lot of flowers, *New Duchess*, *Border Witch*, *Mary Scott*, *Mrs. C. F. Gordon* being seen to advantage in his collection.

Mr. W. Sydenham, Tamworth, staged a few examples of his artistic work for arranging with Pansies, which appeared to interest many visitors, but his choice of colours in their arrangement might have been much better. Messrs. I. House and Son, Bristol, also staged a large collection of Sweet Peas, embracing many of the latest novelties, and in colours of the most pleasing description.

NATIONAL ROSE SOCIETY.

CRYSTAL PALACE, JULY 2.

NOT only from the point of view of the society alone, but also from the exhibitor's and grower's standpoint was this show a success. Throughout the entire exhibition the show may be said to be this, and as in most cases competition was keen, no honours could be said to have been easily won. Many of the exhibits were of the highest order, a remark which applies to nurserymen and amateurs alike. It was impossible to refrain from noting the leading blooms in the leading classes. Particularly prominent was that splendid variety *Mrs. W. J. Grant*, which occupied a conspicuous place in every winning stand; indeed, from no important winning stand was this fine Rose absent, while the lovely *Comtesse de Nadaillac* appeared almost as popular and well grown. The exhibition of 1898 was a credit to the National Society, and equally so to the essentially English flower which it represents and does so much for and wide to popularise.

NURSEYMEN.

In class 1, division A, for seventy-two blooms, distinct varieties, Mr. B. R. Cant, Colchester, secured the first prize with a superb lot of blooms. In this fine exhibit, where all were so uniformly good, it is difficult to specialise, though we cannot refrain from mentioning such handsome blooms as *Ulrich Brunner*, *Captain Hayward*, *Caroline Testout*, splendid in form, size,

and colour; Marie Finger, Alfred Colomb, Souv. d'un Ami, Maman Cochet, Prince Arthur, very rich and fine; General Jacqueminot, Mrs. Sharman Crawford, grand; Catherine Mermet, Duke of Edinburgh, and Mrs. W. J. Grant, a fine-formed and well-finished flower, the second prize in this class going to Messrs. F. Cant and Co., also of Colchester, whose blooms of La France, Beauty of Waltham, Duke of Edinburgh, The Bride, Mrs. Frank Cant, and Margaret Dickson elicited great admiration. Other charming flowers in this lot were Marie van Houtte, most lovely in colour; Mme. Montel, a fine pink, with large shell like petals; Eugénie Verdier, Vicomtesse Folkestone, exquisite; Gustave Piganeau, and J. W. Pawle, a fine rich crimson. Messrs. Harkness and Son, Bedale, secured the third prize with handsome flowers of White Lady, Duke of Teck, Duke of Edinburgh, Mrs. Sharman Crawford, Jeannie Dickson, Vicomtesse Folkestone, a lovely toned flower; Horace Vernet, Niphotos, La France, all being in splendid form. The silver medal bloom in this class was a grand flower of Mrs. W. J. Grant, shown by Messrs. Paul and Son, Cheshunt. For forty distinct varieties, three blooms of each, Mr. Benjamin R. Cant, of Colchester, again took the premier place with a superb lot of flowers. His sets of La France, Mrs. John Laing, Duke of Edinburgh, Gustave Piganeau, Mme. Gabriel Luizet, General Jacqueminot, Margaret Dickson, Mrs. Sharman Crawford, Suzanne Marie Rodocanachi, and Mrs. W. J. Grant defy description. All these were of grand size, superbly finished, the whole being remarkable for size, uniformity and freshness. Messrs. Dickson and Sons, Newtownards, co. Down, were second with smaller, though nice blooms. In this lot, Bridesmaid, Mme. de Watteville, The Bride, Miss Bessie Brown, Mrs. Sharman Crawford, Duke of Edinburgh, and Mrs. W. J. Grant were among the gems of a good all-round lot, Messrs. F. Cant and Co., Colchester, securing the third prize, having good examples of Mrs. Sharman Crawford, Margaret Dickson, La France, Cleopatra, Captain Hayward, Lady Mary Fitzwilliam. In the class for forty-eight blooms distinct, Messrs. Prior and Son, Colchester, obtained the first prize, the most notable blooms being Magna Charta, very fine; Mrs. Sharman Crawford, Margaret Dickson, The Bride, Ulrich Brunner, Marchioness of Dufferin, Prince Arthur, Caroline Testout, superb blooms; Gustave Piganeau, Mrs. W. J. Grant, excellent; La France, Mrs. J. Laing, Chas. Darwin, Cleopatra, White Lady, A. K. Williams, and Lady Mary Fitzwilliam, all being of the finest description. The second prize went to Messrs. Townsend and Sons, Lower Broadheath, Worcester. Here Caroline Testout, Marie Verdier, Souvenir d'Elise Vardon, Ulrich Brunner, Alphonse Soupert, Marquise Litta, Magna Charta, Mrs. J. Laing, and Gustave Piganeau were, among others, of the finest possible form and colouring. Messrs. Burrell and Co., Cambridge, were a close third with La France, Ulrich Brunner, Kaiserin Augusta Victoria, very fine; Victor Hugo, Vicomtesse Folkestone, Mrs. W. J. Grant, Suzanne Rodocanachi, and others. For twenty-four distinct varieties, three blooms of each, Messrs. D. Prior and Son, Colchester, secured the premier position with a most imposing lot of blooms. In this set Souvenir de S. A. Prince was a grand flower, and equally fine was Kaiserin Augusta Victoria, while other superb and highly-finished blooms were Gustave Piganeau, Mrs. J. Laing, Lady Mary Fitzwilliam, a most handsome triplet; Mrs. Sharman Crawford, Mrs. W. J. Grant, and Souvenir d'un Ami. The second prize was secured by Mr. Geo. Prince, Oxford, with fine trebles of Mrs. W. J. Grant, Marchioness of Dufferin, Golden Gate, very distinct; Princess of Wales, Maréchal Niel, Alhambra, Bridesmaid, La France, and Comtesse de Nadaillac, the last perhaps the most exquisite of all in this fine lot. Mr. Chas. Turner, Slough, was third with a fine lot of blooms, among which Helen Keller, fine rosy cerise, very full; Pride of Waltham, La France, Vicomtesse Folkestone, very fine; Mrs. Sharman Crawford, Mrs. J.

Laing, and Ulrich Brunner were the best. For twelve distinct varieties sent out by Messrs. Dickson, Newtownards, co. Down, the firm named secured the Dickson challenge cup, presented to the society by Mr. C. J. Grahame, vice-president, the best blooms being Mrs. Sharman Crawford, Killarney, a lovely flesh-tinted flower, Muriel Grahame, Countess of Caledon, Mrs. W. J. Grant, a prime flower, and Helen Keller, very brilliant. Messrs. Frank Cant and Co., Colchester, were second with splendid examples of Mrs. Sharman Crawford, Mrs. W. J. Grant, Margaret Dickson, and Countess of Caledon. In the class for 12 distinct varieties, to include Teas and Noisettes, Mr. J. Mattock, of Oxford, came first, with a beautiful lot of blooms, though unfortunately unnamed. In this instance boxes were disallowed, the trusses—seven of each kind—being arranged in vases, the blooms, as also the style of arranging, being specially meritorious. Two of the best here were Vicomtesse Folkestone and Mme. de Watteville. Messrs. Paul and Son, Old Nurseries, Cheshunt, secured the second prize with excellent bunches of Augustine Guinoiseau, Gloire Lyonnaise, Belle Siebrecht (syn., Mrs. Grant), Marie van Houtte, beautiful in colour; La France, Violette Bouyer, Mme. A. Chateau, &c. For 24 blooms (Teas and Noisettes), Mr. George Prince, Oxford, was first, his Innocente Pirola, Rubens, Ernest Metz, a superb flower; Princess Beatrice, Hon. Edith Clifford, very handsome and beautifully formed; Cleopatra, Catherine Mermet, Souv. d'un Ami, being of sterling merit. This exhibit also contained a magnificent bloom of Comtesse de Nadaillac, which gained the silver medal as the best of its class. It was certainly a superb flower. Messrs. D. Prior and Son, Colchester, obtained the second prize with fine examples of The Bride, Souv. d'un Ami, Cleopatra, Souv. de S. A. Prince, Ernest Metz, a charming rose-carmine; Maman Cochet, Marie van Houtte, Mme. Hippolyte Jamain, and Caroline Kuster. For 12 blooms (Teas and Noisettes), Mr. J. Mattock, Oxford, took the leading place, The Bride, Rubens, Ernest Metz, Jules Finger, Amazone, a fine deep lemon yellow, charming in the bud state, and Souv. d'Elise Vardon being very fine; the second prize going to Messrs. Burrell and Co., Cambridge, who had good blooms of Luciola, Medea, Jean Ducher, Niphotos, Mme. Lambert, Maman Cochet, Catherine Mermet, &c. For eighteen distinct varieties (three of each variety) Mr. Geo. Prince, Oxford, was first, such triplets as Souv. de S. A. Prince, Luciola, Souv. d'Elise Vardon, Catherine Mermet, Innocente Pirola, Medea, Ernest Metz, Comtesse de Nadaillac (a grand flower), Mme. Cusin (very showy), Marie van Houtte (superbly coloured), Rubens, and Bridesmaid being among the best in this remarkably good, even lot of blooms. Messrs. Prior and Son, Colchester, secured the second place with good specimens of Amazone, Alhambra, Jean Ducher, Ernest Metz, Maman Cochet, Mme. de Watteville, Catherine Mermet, The Bride. For thirty-six distinct varieties of garden or decorative Roses the competition was keen, and it is gratifying to see this useful section, as opposed to the merely stage or exhibition kinds, receiving such prominence at the hands of this the greatest society for furthering the culture of the Rose in this country. As may have been expected, the whole of these exhibits made an unusually attractive display and received marked attention from visitors. The Messrs. Paul and Son, Old Nurseries, Cheshunt, here gained the premier position with a most telling lot of bunches, well arranged. A few of the best were l'Idéal, Maman Cochet, Royal Scarlet, Mme. P. Ducher, Alister S. Gray, Gustave Regis, W. A. Richardson (very showy), Mme. Falcot, Mme. E. Resal, the lovely new white single Una, and others being all excellent, fresh looking, and showy in the extreme. The second prize went to Messrs. Geo. Cooling and Sons, Bath, for handsome bunches of Mme. Laurette Messimy, Isabella Sprunt, Marquis of Salisbury, a very telling crimson; Mme. Georges

Bruant, fine white; Princesse de Monaco. The first prize for eighteen varieties was gained by Mr. J. Mattock, Oxford, who had good bunches of Safrano, Mme. P. Ducher, Ma Capucine (lovely salmon and copper), Marquis of Salisbury, Hebe's Lip, Janet's Pride, Claire Jacquier, Homère, &c., Mr. Charles Turner being second with among others, Bardou Job, Celina, Mme. Pernet-Ducher, Anna Marie de Montravel (pure white), Moschata alba, &c. For twelve blooms of Hybrid Teas, Mr. B. R. Cant, Colchester, was first with La France, Lady Mary Fitzwilliam, Marquise Litta, White Lady, La Fraicheur, &c., Messrs. Prior and Son being second—Caroline Testout, La France, White Lady, W. J. Bennett, Gloire de Lyonnaise, Vicomtesse Folkestone being the best. For twelve blooms of any yellow Rose, Messrs. Prior and Son, Colchester, came first with a lovely box of Marie van Houtte, Mr. Geo. Prince securing the second prize with a dozen grand blooms of that sterling yellow, Maréchal Niel, while Messrs. A. Dickson, Newtownards, Co. Down, took the third place with nice fresh blooms of Marie van Houtte. In the class for twelve blooms of any white Rose, Mr. Geo. Prince, Oxford, was a good first with magnificent examples of Souv. de S. A. Prince, superb in size and form, and in the very pink of condition, Mr. B. R. Cant taking the second place with large and massive blooms of Margaret Dickson. For twelve blooms of any light or dark crimson, Mr. Chas. Turner, Slough, took the first prize with handsome flowers of Ulrich Brunner, Messrs. Townsend coming second with Gustave Piganeau, and the Messrs. Harkness and Sons, Bedale, taking the third place with richly coloured blooms of Horace Vernet. For twelve blooms of any light or pink Rose, Mr. B. R. Cant came first with a superbly coloured dozen of Mrs. W. J. Grant, while for twelve blooms of any Tea or Noisette, Mr. Geo. Prince, Oxford, obtained first prize, his dozen blooms of Comtesse de Nadaillac being faultless. Messrs. Townsend and Sons, Worcester, were second with a charming lot of Rubens. For nine blooms of any new Rose, Mr. B. R. Cant was first with Mrs. W. J. Grant in splendid form, Messrs. A. Dickson and Co. taking second place with a handsome pink kind called Ulster. For twelve new Roses, distinct, Mr. B. R. Cant was again in the premier place, Souv. de Jeannie Cabaud, Tom Wood, Souv. de President Carnot, Empress Alexandra of Russia, Beauté Lyonnaise (a fine white), and Mrs. Rumsey being his best. Messrs. A. Dickson, Co. Down, had Mrs. Mawley, Bessie Brown, Mrs. W. J. Grant, and Brightness, the last an intense velvet crimson shaded flower. For twelve single Roses, distinct, Messrs. Geo. Cooling and Sons, Bath, were first, having Crimson Bedder, Paul's Single White, Macrantha, Rugosa alba, &c.

AMATEURS.

For thirty-six blooms, distinct, Mr. E. B. Lindsell, Bearton, Hitchin, secured premier honours with an even and highly creditable lot of blooms. Among the finest were Mrs. John Laing, a grand bloom, which was selected for the silver medal; Bridesmaid, Mme. Cusin (very good), Louis van Houtte, Ernest Metz, Gustave Piganeau, Duke of Wellington, Duchesse de Vallombrosa (charming in colour), Earl Dufferin, Duke of Edinburgh, &c. For twenty-four distinct, Mr. F. W. Flight, Twyford, secured first prize with a nice lot, his Dr. Andry, Chas. Gater, Caroline Testout, Ulrich Brunner, Comte Raimbaud, and Mrs. Sharman Crawford being excellent. For twelve distinct blooms, three of each, Mr. E. B. Lindsell, Hitchin, took the leading place, having handsome trebles of such as Ernest Metz, Souv. d'Elise Vardon, Capt. Hayward, Duke of Wellington, &c.; Mr. T. B. Hayward, who set up good trios of La France, Gustave Piganeau, Pierre Notting, Mme. G. Luizet, &c., being second. In the class for twelve blooms of any Rose except Teas or Noisettes, Mr. C. J. Grahame came first, having White Lady in grand form, the same variety securing the silver medal awarded for excellence. For eighteen blooms, distinct, Mr. C.

Jones, Hucclecote, Gos., was first with Tom Wood, Mrs. Grant, Chas. Darwin, Kaiserin Augusta Victoria, &c. For eight distinct varieties, Mr. R. E. West took the first prize, Mrs. S. Crawford, Capt. Hayward, and Margaret Dickson being the best. For nine blooms, Tea or Noisette excepted, Mr. E. M. Bethune, Horsham, was first with Kaiserin Augusta Victoria, Rev. H. A. Berners, Harkstead Rectory, being second with Margaret Dickson. For twelve blooms, distinct, Mr. G. Moules, Hitchin, was first, Prince Arthur, A. K. Williams, Rubens, and Maman Cochet being among his best. For nine blooms, distinct, Mr. J. C. Trueman came first, his best blooms being La France and Caroline Testout. For six distinct varieties, Mr. J. A. Hammond, Burgess Hill, was awarded first prize, having La France, Margaret Dickson, &c. For twelve distinct varieties, Mr. G. Moules obtained first prize, having Fisher Holmes, Horace Vernet, Rubens, Hon. E. Gifford, &c., the second prize going to Mr. L. Parry, Dorchester. For nine distinct Roses, including Teas and Noisettes, the Rev. J. H. Pemberton obtained the first place, showing in good form such as Comtesse de Nadaillac, Mrs. Grant, Caroline Testout, &c. In this case seven trusses of each variety were needed and boxes disallowed, the exhibits being set up in vases or similar receptacles. The next three classes were devoted to amateurs who had never taken a prize at any National Rose show, the first place being taken by Mr. J. Carter, Mill House, Halstead, who showed Niphotos, Mrs. Laing, and Caroline Testout, Mr. J. Hinton, Bathaston, and Mr. G. Moor, Arundel, taking first places respectively in the other classes referred to. For eighteen blooms distinct (Tea and Noisette), Mr. A. Hill-Gray, Beaulieu, Bath, had a grand lot of flowers: not only in size and form, but for freshness and finish these were superb. Particularly good were Cleopatra, Bride, Bridesmaid, Maman Cochet, Hon. Edith Gifford, Comtesse de Nadaillac, Souv. d'Elise Vardon, &c. For twelve distinct, Tea and Noisette, Mr. A. Hill-Gray again took the leading place, showing well Ernest Metz, Maman Cochet, Souv. de S. A. Prince, Alba rosea, &c. In the class for eight varieties Mr. A. Hill-Gray, Bath, again displayed excellent form, showing, as in the preceding classes, really a grand lot of flowers. For twelve distinct blooms, Mr. Conway Jones, Hucclecote, Gloucester, was first, having Bride, Medea, Ernest Metz, &c., Mr. R. F. Hobbs coming second. In the amateurs' section for garden or decorative Roses Mr. A. Tate, Leatherhead, took the first place for twelve bunches, showing Perle d'Or, Safrano, Marquis of Salisbury, Hebe's Lip, Gustave Regis, very fine, and W. A. Richardson. For nine similar bunches Mr. A. F. Perkins took the leading place, having a fine lot of Mme. C. Guinoiseau, a rich and showy yellow, very free. Carmine Pillar and Mme. P. Ducher were also good. The second prize went to Miss Dorothy Nesfield, who had good Janet's Pride, Gustave Regis, Rugosa alba, &c. In the class for twelve vases of Penzance Sweet Briers, not less than six varieties, Mr. O. G. Orpen, Colchester, was first with such as Lord and Lady Penzance, Lucy Ashton, and Brenda, a rather showy pink; Mr. F. W. Campion, Reigate, taking second prize, his Flora Melvor and Meg Merrilies being very showy. For a vase of cut Roses, arranged with ferns and grasses, open to ladies, Mrs. O. G. Orpen took first prize, Mrs. Mawley, Rosebank, being second. These were pleasing light arrangements in each case, ferns, grasses, Polypodium aureum, and Asparagus being the chief things employed with Roses.

The gold medal of the society for the best new garden Rose was secured by Messrs. G. Cooling and Sons, Bath, for the new Rose Purity, a snow-white kind, very free and profuse according to the plants shown.

MISCELLANEOUS.

The mixed and other groups at the above meeting were by no means numerous, extensive collections of hardy plants coming from well-known sources and embracing all the most popular hardy flowers in season, Messrs. Barr and Sons, Messrs.

Jaekman, of Woking, Messrs. Cheal, of Crawley, all bringing a goodly assortment of the best hardy things, among which many fine Larkspurs were quite a feature. In the group from Messrs. Wallace, Colchester, were many beautiful things, such as Lilies in abundance, the noble L. Witte, with its golden central band on a snowy white ground, rendering it quite unique. Other Lilies included the lovely L. rubellum, L. menadelpium, L. Hansoni, L. umbellatum and L. Thunbergianum forms, many charming Ixias, a bold array of Hemerocallis aurantiaca major, very showy, Calochortus in plenty, Ornithogalum arabicum, &c. The Messrs. Veitch and Sons, Chelsea, had a splendid lot of pot Roses, well-grown plants, dwarf and nicely flowered; these were supported by Palms, Bamboos and the like and margined with Eurya latifolia variegata, while from Swanley Messrs. Cannell and Sons sent an imposing bank of Cannas in the leading sorts. Messrs. J. Laing and Sons, of Forest Hill, also sent a very beautiful group composed of double Begonias, interspersed with Palms, Caladiums and other fine-foliaged plants. They also showed baskets of cut flowers and an assortment of hardy flowers. Messrs. Dobbie and Co., Rothsay, exhibited a fine and varied lot of Tufted Pansies and Sweet Peas. The Messrs. Laxton Bros., Bedford, sent several baskets of their new Strawberries, including Leader, Mentmore and Royal Sovereign, the fruits large, but the colour seemed lacking.

A full prize list will be found in our advertisement columns.

National Carnation and Picotee Society.—We are asked to state that in consequence of the lateness of the season the show is postponed until Wednesday, July 27. The tickets of admission to the Crystal Palace issued for the 20th will stand good for the postponed date, the 27th, and no others will be issued.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, July 12, in the Drill Hall, James Street, Westminster, 1—5 p.m. On this occasion special prizes will be offered for Roses, and at 3 o'clock a lecture on "Edible Peas" will be given by Mr. N. N. Sherwood.

NOTES OF THE WEEK.

Ostrowekia magnifica.—We learn that this handsome Bellflower is now blooming in the gardens at Hamslade, Bampton, N. Devon.

Pæonia albiflora striata is a curiously striped single form that will find some admirers, although it is somewhat smaller than the majority of kinds. The slightly cupped flowers are heavily striped with reddish carmine on a white ground.

Sweet Pea Princess May is of a very pretty shade of blue-mauve that renders it pleasing in any arrangement of these forms of Lathyrus odoratus. Another very charming thing in the same shade is Lady Nina Balfour, a very pleasing soft mauve tone.

Iris juncea and its variety *numidica* are among the most indispensable of bulbous Irises for early July. The rush-leaved forms come when the majority of the Spanish kinds are passing and are therefore welcome in their lovely and distinct shades of yellow.

Phlomis Russelliana.—This very distinct hardy perennial is too little known, or at least but only rarely seen in good condition. It is quite removed from a large number of hardy perennials, the leafage as well as the large whorls of yellow and white flowers being very striking in a group.

Rose Lady Mary Fitzwilliam.—This variety is a great success this year, some of the flowers being of large size, and the bulk generally of a meritorious character and fine in colour. Quite small bushes, too, have produced a large number of handsome flowers that will please those who require a good garden Rose.

Lupinus polyphyllus Somerset.—In the soft yellow of the blossoms that crowd the flower-spike of this plant there is little to distinguish it from the well-known Tree Lupine (*L. arboreus*), which species probably had something to do with the new-comer,

which will be an acquisition. The tone of yellow is so soft and pleasing that should the plant prove a good vigorous grower, in common with border Lupines generally, it will make a valuable addition to hardy plants.

Hemerocallis aurantiaca major.—The Day Lilies can boast no more handsome or beautiful kind than this, which surpasses all else in its rich and telling shade of colour. The plant, moreover, is of the same easy culture as are all the race, and therefore of great value in the garden. So good a plant deserves to be grown very freely.

Rose Mrs. W. J. Grant.—It speaks volumes for the popularity of any flower, quite apart from the reliable character of any variety of Rose, to see it included in every winning stand where its inclusion is permissible. This was so with the above at the Crystal Palace show last Saturday, and in many instances the blooms simply faultless in size, colour, and form; some, indeed, were magnificent.

Begonia Florence Nightingale.—The possibilities of any group of so-called florists' flowers appear unknown, yet one may reasonably assume that for size, purity of colour, dwarfness of habit and remarkable freedom of flowering it would be difficult to surpass this handsome kind. The flowers are of snowy whiteness and remarkable for size, while the habit of growth is all that can be desired.

Lavatera arborea variegata.—Three splendid examples of this from Messrs. Cannell attracted a good deal of attention at the Drill Hall last week. The specimens in question were between 3 feet and 4 feet high and nearly 3 feet through. The plants were about three years old and retained their variegated character in a surprising manner. Root room was, however, limited, and this may have served to keep down excessive vigour.

Buddleia globosa.—There is a magnificent plant of this Buddleia in a garden close to the electric tram line from Kingstown to Dublin. It exceeds the height given by Mr. Bean as that usually attained by this species in this country, and must be at least 15 feet high. Mr. Burbidge told me that it had not been cut back by any of the winters. It was very fine last month and covered with its yellow balls.—S. ARNOTT.

Silene alpestris.—The pretty shining prostrate tufts of this plant are now covered with singularly beautiful pure white blossoms, which, though not large in themselves, are produced in such quantity as almost to hide the greater part of the tuft. For the rock garden it is a capital plant, though it would be impossible to surpass the free carpet of growth and numerous blossoms that result when the plant has attained a large size in good border soil.

Campanula G. F. Wilson.—This charming little hybrid Bellflower is now in full bloom on the rockwork. The excessive amount of rain which fell last winter did not seem to agree with it, and at first it made rather weakly growth. Now it has made considerable progress and is covered with its pretty semi-drooping deep blue flowers. If occasional dressings of bone-dust are given, its vigour is much increased. S. ARNOTT, *Carsethorn, by Dumfries.*

Pink Albino.—So far as purity is concerned, together with form and substance of petal, this is, perhaps, one of the finest Pinks ever raised. So far, however, the small plants do not appear to possess the requisite vigour or freedom for a first-class border Pink. The plants referred to, it should be stated, are certainly not large, and it is possible another year may see some improvement in what is certainly a very beautiful and highly fragrant kind.

Phenocoma prolifera Barnesi.—This free-flowering New Holland shrub, that we are so accustomed to see twisted unnaturally around a wire frame, was shown at the Drill Hall a week ago in a far more natural style. The plants had apparently been grown to about 9 inches high and then stopped, and with but little after-pinchng allowed their own way, finally forming large handsome heads, which were a mass of rich bright blossoms. In this way this plant is much more serviceable for grouping.

Sweet Brier Anne of Gerolstein.—At Straffan most of Lord Penzance's Hybrid Sweet

Briers are luxuriant and free-blooming, but the above kind, nearly 20 feet in height and with drooping branches set with rosy crimson flowers, is just now one of the best. For poles, arches, pergolas, dead shrubs or trees, &c., these Sweet Briers are a great gain, as scarcely anything could be more elegant in habit, so free-growing, so sweet and fresh in leafage, or having more variety in their blossoms. For planting in hedges near the house or for covering fences they would be charming. It does not appear to be generally known that cattle refrain from cropping the Sweet Briers, but it is a fact well worth remembering.—F. W. BURRIDGE.

The Mocassin Flower (*Cypripedium spectabile*) at Straffan.—There is now a bed of this consisting of twenty-four clumps, and in all bearing 451 flowers. Two of the largest plants bear thirty-five flowers each, and about 60 or 70 per cent. of the spikes are twin-flowered. There is some little variety in form and colour, but all the blossoms are very large and shapely, the sepals and petals pure white, and the swollen lips more or less rosy. This bed is eight or nine years old and is the result of fine dry clumps bought at the sale rooms. As thus seen, luxuriant in the open air, each stem 18 inches to 2 feet in height, no tropical Lady's Slipper could be more handsome. The results are so fine that I wish Mr. Bedford would kindly tell us his treatment as to soil and aspect, &c.—F. W. B.

Lilium Wittei.—There is no more beautiful Lily than this in the whole of the auratum group. The exceeding purity and great substance of its petals are marked features of this rare and handsome kind, several flowers of which from Messrs. Wallace, of Colchester, appeared at the Drill Hall last week. In the plant shown the habit is quite dwarf, not more than 2½ feet above the pot, and in this way its handsome flowers were seen to advantage. The pure blooms seemed but enhanced by the well-defined golden-yellow band down the centre of each segment. This is saying much, seeing the anthers were fully ripe, so that much care was needed to exhibit it in such perfect form. It is a superb Lily in every way, and worth every care.

Lilium Marhan.—This is the new hybrid Lily which secured a first-class certificate last week at the Royal Horticultural Society, and as a garden Lily should prove of considerable merit. It is also likely to prove of easy culture by reason of the parentage, viz., a Martagon form and *L. Hansonii*. The latter species is strongly in evidence in the hybrid, so much so that one might reasonably assume this to have been the pollen parent in this case. In the whorled character of the leaves and stems, and not less so in the general contour of the blooms, their size, &c., there is a marked character of *L. Hansonii*, the time of flowering also agreeing with that of this species. The colour, too, bears evidence of the cross, which is quite distinct from that of the species named. The new-comer should prove of service in the garden where room will always be found for new and valuable plants.

Primula Trailli.—Lovers of hardy plants generally have reason to thank Mr. G. F. Wilson for the infinite pains he has taken concerning the identity of the plant exhibited by him before the floral committee of the Royal Horticultural Society a little more than a year ago under the above name, and so far everything is very gratifying. At the same time, the very anxious desire of the majority of the floral committee to grant awards in such cases would appear to render the verification of any so-called new species in future a sort of necessity either by the Kew authorities or a sub-committee of hardy plant specialists acting in conjunction with the floral committee. It was, I know, very clear to a few hardy plant men that the plant in question was but a form of *P. involucrata*. An opinion to this effect I gave in the pages of THE GARDEN at the time, not being a member of the floral committee. The frankness of Mr. Wilson now places the matter in a clear light, and seeing the award made by the floral

committee was intended for *Primula Trailli*, this committee has but one course to pursue and unreservedly withdraw the award in question.—E. JENKINS, *Hampton Hill*.

Foxgloves and Larkspurs: A beautiful effect.—There is now a singularly pretty effect at Batsford Park of white and spotted Foxgloves, tall and well grown, covering a large space in a young and open plantation, with here and there the tall spikes of blue Delphiniums, these coming from stock to spare in the garden. The Foxgloves of the best spotted and white kinds at first were sown broadcast and afterwards renewed themselves. Where the white or creamy kinds come together and the slender blue spikes of the Larkspurs arise near them, the effect is beautiful and singular. This is only one of many charming combinations of this kind that might be made in what we might call the shrubby garden—that is, instead of crowding the undergrowth of precious trees and shrubs with Laurel, Privet, and such things, planting free-growing hardy plants like these. It is very easily done, and there is scarcely a garden where there are not lots of beautiful things among perennials which are overgrown and ready to be planted elsewhere. Such gardening well done is really more beautiful in colour than anything in the regulation flower garden almost, owing to the fine backgrounds and the aid of rising stems of shrub and tree.

Tropæolum polyphyllum.—That this free-flowering and handsome trailing species is grown in some quantity is shown by the numerous branches of it among the exhibits at the Drill Hall last week. It is in many respects a valuable species, and may be put to a variety of uses in the garden, by reason of its freedom and the way in which it adapts itself so readily to varied positions. It is, perhaps, the most persistent grower of its race, springing up through hard gravel walks several feet away from the spot where the original tubers were planted. In the rock garden in sloping positions it is especially attractive if allowed to ramble at will and not tied up to sticks as is sometimes seen. If it is desired to train it erect, the sprays or boughs should be placed quite early in position, but the plant is not so well suited for this, as there are no tendrils to cling or climb with. Rambling prostrate over rocks the effect of yellow blossom and glaucous leafage is quite marked, and a group thus placed is sure to attract attention. The plant being so easily managed and distinct in character may also be employed for window boxes or large vases in the garden. If necessary the tubers receive no injury by being lifted each year and stored away in a dry place.

Campanula mirabilis.—A small flowering plant of this much-talked-of species came before the floral committee of the Royal Horticultural Society last week and obtained a first-class certificate. Seeing the flowers of this Caucasian species come so near to those of some of the forms of *C. Medium*, it is strange so dignified an award was bestowed upon it. By a singular coincidence the Messrs. Veitch and Sons were at the same meeting the exhibitors of a splendidly-grown batch of these Canterbury Bells, such as are rarely seen in the open ground, much less as pot plants pure and simple. Yet these splendid examples, well known and tried as of rare horticultural value, received not the least recognition from the society, not even an "award" for the excellence of the strain, or even a cultural commendation, both of which the exhibit justly deserved. Thus grown the plants surpass all else of their kind ever staged at the Drill Hall. The plants of *Campanula Medium calycanthema* exhibited could hardly have been better done; they certainly could not have been more truly representative of the strain, which was an exceptionally good one, or have produced larger blossoms more greatly varied in colour. I am not now assuming that the example of *C. mirabilis* was a representative one, for the plant is said to form a pyramidal branching bush 2 feet high, bearing hundreds of the pale blue flowers. What I say is that the

plant shown insufficiently indicated its horticultural value, and that the higher award may have been withheld for a time. From a purely garden or decorative standpoint, were I asked my opinion, I should unhesitatingly favour the excellent strain of *C. Medium* above noted as calculated to serve a far wider sphere of usefulness than is the above novelty, so far as present experience can judge. I doubt not, however, that those who have large rosettes of *C. mirabilis* more than a foot across will expect to see a handsome pyramid of bloom that will not wholly disappoint at flowering time. The flowers are of a pretty pale blue tint and the plant evidently a profuse bloomer.—E. JENKINS, *Hampton Hill*.

Orchis maculata superba.—I noticed an article in THE GARDEN (p. 553) about *Orchis maculata superba*, and I give you my experience of it. The plant from which I got my present piece was planted upwards of thirty years ago, and it has never been disturbed, a small piece being taken off occasionally for a friend. A grand clump it is, too, so the theory of dividing will not hold in this case. The last garden I had charge of was in Ayrshire, very close to where it was discovered. I grew it there very well; in fact, I had longer spikes there than I have ever seen since. About twenty years ago I sent a spike to the editor of THE GARDEN, and the length of inflorescence was 13 inches. I would like to know if that has ever been surpassed. I was not content to let well alone. I wished to increase it, and when the plant was dying down it was taken up and the tubers separated, with the result that in two years there was not a single plant left. The plant here has been in the same place for nine years, is as healthy as ever, and it has twenty-eight spikes of bloom to-day. The only thing it requires is a little top-dressing in the autumn with fresh loam as the roots come to the surface. I have often seen it planted in old garden soil, but in a year or two it had disappeared. I take out the old soil to the depth of 2 feet and fill in with fresh loam, and that seems to suit it.—JOHN HARPER, *Kirkconnell Gardens, New Abbey*.

OBITUARY.

MR. WILLIAM MILLER.

WE regret to announce the death of Mr. William Miller, author of "A Dictionary of English Plant Names." He was a man of varied learning and who took much interest in native and other plants. From a very early age he was an accomplished scholar, and for several years had been head classical master at Stackpoole's famous school at Kingstown and afterwards at Ennis College, having taken first honours at Trinity College in classics and mathematics. He died at Ballycanew, Ireland, at the age of 67 years.

The weather in West Herts.—At the beginning of the week the weather was rather warm, but during the last few days the temperatures have been somewhat below the average. At 1 foot deep the ground is of about average warmth, but at 2 feet deep it still remains rather cold for the time of year. On two occasions rain fell, but taken together the fall only amounted to about a quarter of an inch. During June the temperature was very variable; indeed, during the course of it there occurred three distinct warm and three distinct cold periods. Taken as a whole, it was with two exceptions, 1886 and 1892, the coldest June during the past thirteen years. Rain fell on thirteen, or about the usual number of days for the month, but only to the depth of an inch, which is less than half the June average. The record of sunshine was small, only averaging 6½ hours a day, or an hour short of the mean for the month. The Junes of 1888, 1890, and 1894 were, however, more sunless.—E. M., *Berkhamsted*.

ORCHIDS.

CATCLEYA SUPERBA.

The long life or otherwise of this fine *Cattleya* is always doubtful, and among a batch of imported plants some are sure to continue in health longer than others. Now and then one comes across fine plants that have been grown on year after year, but it is not so often as one might wish. Scores of plants die annually, the life of a plant in many cases not exceeding half a dozen years under cultivation. Lately some cultivators have been very successful with it by giving less heat than was formerly advised, but this is only one of the methods that have been tried and found to succeed for a time only. There is no doubt that it has been overdone with heat in some instances. Not that the heat itself is harmful; indeed, if a plentiful supply of air is always moving over the foliage, I question if it could by any reasonable means be kept much too hot. But heat and moisture without due regard to the consolidating of the growth will not do. Large pseudo-bulbs are an advantage no doubt, but they must be exposed to the summer sun and abundant air currents to thoroughly ripen them. It is more necessary for this species than for any other *Cattleya*; in fact, few other species will stand so much sunlight. Another point is to keep the water supply going until the bulbs are really fully developed, for a plant starved in autumn has not the power to break strongly in spring, and is the first to shrivel from want of water during the winter's rest. I never like to see *C. superba* shrivel in the least while at rest, and while a distinct resting season is required, the water supply must be kept sufficiently good to prevent this. When growth commences, very little moisture at the root suffices; but when it is well away and root action is also free, a large supply is necessary, the plant having a lot to do in a short time. All these summer-flowering *Cattleyas*, in fact, that push up a young growth and flower upon it at once are alike in this respect. They

take a longer resting season as a rule than those that rest in sheath and make up for it by taking a larger supply of water during the short growing season. The flowers open as the bulb is thickening up, and are of a bright rosy purple shade on the sepals and petals, the lip marked with deep crimson-purple, yellow and white. When the flowers are fully open the plants may be placed in a light and rather cooler house, shading the flowers as long as they are open and afterwards giving almost full exposure to the sun. With regard to the treatment of the roots, it is imperative that something of a lasting character be provided, for they dislike disturbance, and the backward tendency spoken of in many a fine plant dates from the first repotting. I have had finer growth on *C. superba* by using pots or baskets than blocks, but a well-known cultivator has described his method of treatment, which has been satisfactory, and advises the use of Tree Fern stems as blocks. The natural roughness of this material would of course make it more suitable than a bare block of wood, and anyone having this aid to culture may use it with every prospect of success, provided the plants are otherwise well treated. For pots or baskets the compost should be kept very thin, and plenty of Sphagnum Moss rather than peat should be used. Quite three parts of Moss to one of peat will be suitable, and with it plenty of rough crocks. Thrips are very partial to *C. superba*, and unless carefully kept under, this pest soon spoils the appearance of the plants. Vaporising and occasional sponging will soon rid the plant of the insects and must not be neglected. *C. superba* is a widely distributed plant geographically, and it is singular that more variety is not found in the flowers. Discovered early in the present century, it was not cultivated in this country until 1838, when it was sent from British Guiana by Sir R. Schomburgk.

Masdevallia racemosa.—This is a fine species where well done, the racemes of flower occurring with freedom and containing many flowers

of a bright orange shade, suffused with a brighter colour. In habit it is looser than the usual run of *Masdevallias*, the leaves not so tufted, but occurring further apart on a semi-creeping rhizome. Wide receptacles and a compost with plenty of rough open material, so that air and water may enter and leave the compost freely, are necessary.

Dendrobium chrysanthum.—This is flowering at rather an unseasonable time, but the pretty sweet-scented golden-yellow blossoms are welcome. It blooms always upon the newly-made growths, and often while the foliage is still fresh, this giving it a fine appearance. The plants do best and look best in baskets, so that the long cylindrical stems take a natural semi-pendent direction. Rough peat and moss are the best compost, and the growth must be allowed its own way to a certain extent, the temperature being arranged to suit its habit of growing in winter.

Odontoglossum Roezli.—This is a very unreliable plant, some growers getting on with it tolerably well, but others—and these perhaps the majority—being far from successful. Its flowers, too, appear at all seasons, but when really good are sure to be admired. They are each upwards of 3 inches across, white, with a yellow centre to the lip and a purple-crimson blotch on each petal. *O. Roezli* requires more heat than any other species in the genus, with plenty of sunlight and abundance of water at the root. It is nearly always more or less in growth, and should be potted in peat fibre and moss over good drainage.

Læliopsis domingensis.—This is probably the only species in the genus that is at present under cultivation, and is a pretty plant, with somewhat the habit of the Mexican *Lælias*. The flowers occur upon branching spikes and are of a pretty soft rose in colour. *L. domingensis*, coming from the islands of Cuba and San Domingo, requires a warm, moist and very light house while growing, must be thoroughly ripened by exposure to sun and air and well rested. Under this treatment the plants seldom fail to flower, and the roots must either be confined to small baskets or placed on blocks.

Phalenopsis Manni.—This is a pretty Moth Orchid, with branching spikes containing about a dozen blossoms each not more than 2

inches across. The sepals and petals are variable in colour, some of the better forms being of quite a golden yellow, with brown markings, while in others the flowers are nearly white or very pale yellow. It is a species of moderate growth, requiring a fair-sized basket or pot and a thin compost or layer of Sphagnum Moss. The foliage must not be heavily shaded nor must it be wetted much with the syringe, especially in dull weather. The species is a native of Assam, and first flowered in England about 1871.

Catasetum Christyanum.—This singular species I have recently seen in good condition, the spikes of flower very stout, erect, carrying from a dozen to eighteen flowers. The colour may not be attractive enough to find favour with present-day growers, but, all the same, such plants ought always to be grown where anything like a representative collection is aimed at. The sepals are chocolate, the lip purple and green—a rather unusual combination of colour. These plants delight in ample warmth and light while growth is in progress, should be thoroughly ripened by exposure to sun and air in autumn, and have a distinct resting season.—H.

ODONTOGLOSSUM INSLEAYI.

This is a capital plant for the amateur cultivator. Its culture does not present any especial difficulty, though care in all the details must be practised. The habit of the plant is very like that of *O. grande*. The flowers appear on erect spikes about seven or eight on each, and in colour they are bright yellow more or less blotched with reddish brown on the sepals and petals, the lip ornamented with many bright red spots usually about the margin. I know of no better place to grow this *Odontoglossum* than a cool or greenhouse fernery. The atmospheric conditions here are very like those obtaining in the native habitat, and, though possibly the plants could do with a little more moisture than is required for Ferns, a medium course may be made between the two which will do for both. In the Orchid houses proper the plants may be grown in the cool house and fairly shaded during summer. Although *O. insleayi* cannot be said to be constant in its time of growing and flowering, it is not worth while trying to bring it in at any special time. Where a lot of plants is grown, some are sure to be earlier than others, but this is an advantage rather than otherwise, as it prolongs the season of flowering with no harm to the plants, as they like regularly cool and moist quarters all the year round. Large specimen plants of *O. insleayi* are not so often seen as of *O. grande*, and usually the plants sent out from nurseries are so small that they have to be massed to make anything approaching a fine plant. Good masses are sometimes offered at the safe rooms, but when they get into the nurserymen's hands these are soon made less. I do not care for massed plants as a rule, and especially not of a species like this, that varies considerably in colour and markings. Far better keep them single, and grow them on as quickly as possible; they are very free, and soon make nice neat little specimens. They should have pots of medium size, according to that of the plant, and a rough compost suits the somewhat fleshy roots. Pots, say, 8 inches in width may be filled to within 2 inches of the rim with crocks. Allow a fair margin around the plants, or repotting will soon be necessary again, but avoid setting the plants too high. They must be elevated a little, but not so stuck up that the watering is difficult. The plants may be potted just at the time growth is starting, and here it may be noted that the small snails so frequently seen about cool Orchids are very destructive to this plant at this time. They manage to get through the tough outer scales and eat out the embryo flower-spike and part of the young growth, quite ruining the plant in fact.

Moisture at the roots must be regular rather than changing much at the resting and grow-

ing seasons. The plants must not be dried, or they will resent it by shrivelling and pushing weak growths. Besides the typical plant named above, there are several fine varieties, including *leopardinum*, *panthericum*, *splendens*, and others. These differ principally in the colour of the flowers, the last-named being an especially fine one, much larger than the type. *O. insleayi* is a native of Mexico, and was first discovered by Ross about sixty years ago, and sent by him to Mr. Barker, of Birmingham. For a long time it was rare, so many plants having died, but some years later it was again introduced in quantity, and has frequently been imported since.

Odontoglossum cirrhosum roseum.—Under this name I have received flowers of one of the rosy-tinted forms of *O. cirrhosum*, a pretty section that makes a distinct contrast to the ordinary forms, and is beautiful in itself. In the flowers to hand the rose tint is confined principally to the centre of the sepals and margin of the petals, the lip also having a slight suffusion, though this is of a lighter tint. If such fine tints of rose turn up as are occasionally seen in *crispum* they would form a very fine class, but though I have seen many with a tinge of rose, none as yet come up to this standard.—H.

Lælia Wyattiana.—The blossoms of this species, or natural hybrid, although not so broad in the segments or showy as those of many other kinds, are very pretty and distinct and well worth a place. The flowers are each about $4\frac{1}{2}$ inches across, the sepals and petals nearly pure white, and the lip has a deep purple front and yellow side lobes—a pretty combination, not unlike that occurring in *Lælia crispata*. Its culture is not difficult, the plant thriving well in company with *L. elegans*, *L. purpurata*, and others from South Brazil, whence it has been imported occasionally. It is dedicated to the late Mr. G. N. Wyatt, of Cheltenham, with whom it first flowered.

Phalænopsis Luddemanniana.—I noted a fine spike of this species this week bearing six flowers, each about $2\frac{1}{2}$ inches across. The sepals and petals are rather heavily blotched with chestnut-brown on a pale yellow ground, and the lip is bright amethyst-purple and white. Although not particularly difficult to grow when good specimens are procured, this species does not grow so freely as *P. amabilis* or *P. Schilleriana*, and when in indifferent health it is a difficult subject to thoroughly restore. Small baskets are preferable to large ones and the roots are better with only a small amount of compost about them, this consisting of clean Sphagnum Moss and charcoal or crocks only. There are many varieties of this species, which was introduced from the Philippine Islands by Messrs. Hugh Low and Co. in 1864.—H.

Angræcum citratum.—Although a dwarf species, this is a very pretty plant when well grown, the long, semi-pendent racemes of whitish flowers having a fine appearance against the dark green of the foliage. A plant with three racemes has been very pretty with me during the last month, and it deserves a place in any collection. One of the discoveries of Du Petit Thouars during his voyage late in the last century, *A. citratum* was not introduced to this country for many years afterwards, and was then for a long time rare, but subsequent importations have made it plentiful enough. Its native habitat is Madagascar, where it grows in swampy, moist positions on low undergrowth. A hot, moist house is best for it, and although the growth is freer in a dense shade and the plants take on a deep green tint, the flowers are not so freely produced as on plants growing in a good light. In nurseries the plants of this and similar kinds are often packed close together on stages a long way from the glass, but the position most of them, including *A. citratum*, enjoy is one not far from the roof where plenty of light and air is found. The baskets should have a few large pieces of crocks and charcoal in

the bottom, these being lightly surfaced with clean Sphagnum Moss kept growing.—H.

ONCIDIUM CARTHAGINENSE.

It is surprising that some of these eubulous *Oncidiums* are not a good deal more grown, this species, for instance, being as handsome as any in the genus, with finely spotted foliage and very pretty flowers. As a rule, if one comes across a plant of it in an out-of-the-way place it is a poor, half-starved thing that gives but little idea of what the plant is capable of. I have had it with leaves 2 feet and upwards in length, broad and handsomely marked, and the flower-spikes several yards in length, that, looped up to the roof or twining about other plants, have an exceptionally pretty effect, notwithstanding the small size of the individual blossoms. The latter occur on short side racemes all along the principal spikes, and have pretty rosy white sepals and petals, much crisped and undulating, the lip similar in colour, but of plainer outline. The culture of *O. carthaginense* for a few seasons after importing is extremely simple, the plants growing and rooting with great vigour, but unless care is taken every year to thoroughly consolidate the leafy system and to maintain the plants in a hard, sound condition, they will after this lose vigour and eventually make but little progress. As soon as the new growth of a season is seen to be smaller than that of the year preceding it, something is obviously wrong with the plants, and as likely as not it is the want of consolidation referred to. I have before stated in THE GARDEN that these *Oncidiums* from the West Indies and Central America are often kept in too moist an atmosphere. Not but that they like moisture both at the roots and about the leaves, but it ought not to be continual, and a slight drying occasionally with the sun shining fully on their leaves helps to maintain the balance between a soft growth on the one hand and a semi-starved condition on the other. It is so with the species under notice, and much better results will follow this kind of treatment than a course of continuous atmospheric moisture and heavy shade, notwithstanding the healthy appearance of the plants under the latter régime. The treatment of the roots is simple enough, and no difficulty will be found in inducing them to take a firm hold of anything provided for their reception. They do not care for a heavy or thick compost, but always seem most at home and longer-lived when they are rambling about on the outside of a pot or basket in such a position that they are often dry. A thin layer of Sphagnum Moss and peat over abundant drainage and plenty of rough material then may be chosen. In this the roots will frequently run dry and need moisture, a condition conducive to the long life of epiphytal Orchid roots. The temperature of the *Cattleya* house will suit it, or it may be grown with the Mexican *Lælias*. It is one of the oldest of known Orchids, having been discovered in Central America far back in the last century, while it flowered in England in 1804.

Oncidium longipes.—The flowers of this *Oncidium*, produced on small spikes containing about three or four, are very pretty and long-lasting. It is very free flowering, so much so, that almost every young shoot has its flower-spike, and as these come successively, the plants make a show for a long time. The sepals and petals are yellow and brown, the lip brighter yellow with a prominent crest. Not being a very vigorous plant, the receptacles for its growth should not be too large, a flat pan or basket or a pot nearly filled with drainage suiting it well. The plant spreads considerably, so that the pot may be wide in comparison with the plant, the ordinary description of compost suiting it well. At no time is a very heavy water supply necessary, but during summer when the plants are carrying their flowers and developing their growth at the same time they need fairly frequent attention. In winter the roots should not be

dried, the treatment in this way being similar to that recently given for *O. concolor*. The temperature may be rather above that of the *Odontoglossum* house, a cool, moist medium in summer and winter and a fair amount of shade being required. *O. longipes* is a native of Rio de Janeiro, whence it was introduced about 1850, and it has frequently been imported from various other parts of South America.

Epidendrum nemorale.—This is one of the finest of *Epidendrums* and a good garden Orchid, showy, yet delicate, and pretty and very free. The pseudo-bulbs are rather short, but bear long leaves, the flowers appearing at the upper part of the erect spikes. The colour is a pretty shade of mauve with deeper lines upon the lip, but it varies somewhat in different plants. Its habit suits it best for pot culture, the pots being fairly large and well drained, and filled with equal parts of peat fibre and Sphagnum Moss. The plant requires care both in potting and subsequent watering, the roots being easily injured by undue disturbance or a surfeit of moisture. It comes from Mexico, where it is distributed over a large tract of country; and whether from some localities the plants are stronger in constitution or they are collected at a more suitable time I am unable to say, but certainly some do much better than others, though apparently quite as vigorous at first. I have not found it a fastidious plant as to temperature, having obtained good results in a fairly cool house and also when grown with the *Cattleyas*. I should choose the latter for preference, as the growth is more free. During the season of growth it is a very thirsty subject, and being evergreen must not be dried in winter.—H.

THE MARKET GARDEN.

PEACHES AND NECTARINES FOR MARKET.

If the average gardener were consulted as to the possibility of growing Peaches and Nectarines for the markets profitably, the chances are the reply would be decidedly in the negative. A similar reply would also be returned by some market growers of my acquaintance. At the present time I have a span-roofed house 145 feet long fairly well stocked with trees. Peaches would pay fairly well if the price averaged 6s. per dozen fruit, but this I hold to be a low average, 8s., clear of all charges, being nearer the mark. Commencing late in May with 15s. per dozen for the best of the fruit, going up to 18s., this price holding good during the Ascot week, also for a few days preceding and succeeding that week, they gradually drop to 9s. per dozen, at which price all forced Peaches and Nectarines ought to be cleared out. It is only fair to state that these prices are only realised by highly-coloured or moderately well-coloured fruit, the seconds fetching one-third less than the best samples, but of these there ought not to be many to pack, unless overcropping be the order of the day. The cost of production I have not worked out, and can only say that the house devoted to Peaches and Nectarines is less trouble than when planted with Tomatoes, and the amount of fire-heat expended would be about the same as required for Tomatoes—less certainly rather than more. It is private gardeners or men with some previous experience with Peach and Nectarine trees that ought to commence their culture on a moderately large scale to produce superior fruit for the markets. Others who have started without knowing what they were about contrive to get into a rare muddle with their trees, and I could point to a large number of trees run wild and pushing through the glass in all directions. In another case, a private garden rented by a market grower, the trees are being cropped for

"all they are worth," and when that grower has done with them it is not much they will be worth. Such examples serve to bring discredit upon what is really an important industry, those responsible for or suffering from the effects of such blunders naturally having but a poor opinion of that particular branch of horticulture.

BEST MARKET VARIETIES.

Not a little depends upon the choice of varieties. If the beginner "places himself in the hands of a nurseryman," leaving the selection to him, and by so doing getting a few shillings reduction in price, it is just possible he will find this false economy. Some of the varieties received may be admirably adapted for forcing and marketing, and the rest not. A favourite Peach with many is Royal George, but this variety is not one to plant wholesale. It is in some respects too good for the purpose, and, like many more high-class things, possesses a weakly constitution. The trees are liable to become infested by mildew and to fail prematurely. Another fine Peach—Grosse Mignonne—is also, according to my views, unsuitable for market growing, and objections may also be urged against the colourless but luscious Noblesse. Nor do I recommend Alexandra Noblesse, yet all four varieties, and to which I add Stirling Castle, a fine but somewhat soft Peach, are deservedly among the most popular grown in private gardens. Early Beatrice, Early Louise, Early Alfred, and Rivers' Early York are all extra early, and, as a rule, good in quality, but I would not plant any of them. Well-grown fruit of Alexander and Waterloo (they are very much alike) fetch the highest prices, and but for one bad failing of these extra early varieties would be extensively grown. There is no certainty about their holding their buds, and this season I had to leave every fruit that set, or otherwise the crop would have been light. Amsden June is equally early, of the same free habit of growth, and sheds but few of its flower-buds prematurely. On young trees or those growing strongly the fruit is a little under-sized, but as the trees age the fruit improves in size, and this season I had many that were large, handsome, and highly coloured. Trees of Amsden June are fast occupying space previously covered by Waterloo and Early Alexander. To succeed this I grow Hale's Early, which I find one of the best if not the most profitable variety in the house. The fruits are large, of fine colour, and the quality is good. I have never yet failed with it. Early Rivers is a fine early Peach, which I would grow but for its bad habit of stone-splitting. My small tree cannot be cured of this, and is being gradually crowded out. Of Crimson Galande I have nothing but good words to write. It is a grand second early Peach. The trees with me never fail to set heavy crops, the fruits are large, and colour beautifully. Bellegarde is a week or so later than the last-named, and this again is a grand market Peach. Violet Hative is equally easy to grow, the fruit colouring beautifully and selling well. It ripens about the same time as Bellegarde. If yet another variety is wanted for forcing, Dymond should be grown, as it is reliable and good in every respect. As it is not advisable to have too many fruits ripening at one time, especially if they are sent direct to fruiterers, a few trees each of all the varieties recommended may be planted in one long house, keeping the later sorts, if any are grown, by themselves in another house or compartment. There is, however, nothing to prevent late varieties sharing a house with earlier ones, and for a local trade this arrangement may be

advantageously adopted, but as a rule the early and second early Peaches pay best. Barrington would form a good succession to Violet Hative, and the fruits of this variety are large, colouring beautifully, keeping and travelling well. All things considered, no late variety equals Sea Eagle for heavy cropping, size, colour, and quality of the fruit. This variety also keeps and travels exceptionally well. I have never sent any of it to Covent Garden, but am under the impression a house wholly devoted to Sea Eagle would pay well. Those who are on the look-out for something fresh or different from what most other market growers favour should try Salwey, as I believe it would pay anyone to grow it extensively, timing the crop to ripen in October. Peaches are becoming scarce at that date, and although not much can be said in favour of the quality of Salwey, the fruits are large, colour beautifully, and keep well. According to my experience, the trees of no other variety will long stand over-cropping so well as do those of the despised Salwey.

"No money in Nectarines" was the positive assertion of a friend of mine who felt competent to express an opinion on the subject, and much to my regret I was weak enough to accept this dictum. I have since discovered that Nectarines are in greater demand than Peaches and are really the more popular, especially among ladies. Extra fine highly-coloured samples fetch high prices early in the season and sell at profitable rates at all other times. At one time Lord Napier was the best early Nectarine, but this is being fast superseded by Early Rivers, and Cardinal promises to be even more profitable than the last-named. With me a few fruits of Early Rivers ripened at about the same time as Hale's Early Peach, and I have no doubt it will be at least a week earlier in ripening next season. The fault of this handsome Nectarine, if a fault it may be termed, is over-luxuriance, but market growers have a remedy for this, viz., heavy cropping. Lord Napier, a fine Nectarine, forms a good succession to Early Rivers, and to follow this we have Stanwick Elruge, a sure-bearing, highly-coloured variety. Improved Downton is equally reliable, the fruit being moderately large, may be highly coloured, and the quality is good. Pine-apple is one of the richest-flavoured Nectarines available and a good market sort. The heavy-cropping, but less attractive Victoria is also useful to supply late fruit if required.

PREPARATION OF BORDERS.

Market growers cannot afford to form elaborate borders for Peaches and Nectarines any more than they can for Vines. Nor are they necessary. Land that will grow garden crops generally without a great amount of labour expended on its preparation is good enough for Peach trees. My soil happens to be a sandy clayey loam, and answers admirably without much preparation. Span-roofed houses running from north to south and from 14 feet to 20 feet wide, with a roof moderately steep in pitch, are suitable, and much cheaper than three-quarter-span or lean-to structures. Houses with brick walls and glazed sides are most commonly erected, but I am well content with stout wooden pillars and boarded sides 2 feet to 3 feet above the ground level. Having seen the ill effects of exposing the stems to strong sun, I am glad to shade these with the boards, and, knowing that the trees are all the better for being able to root into outside borders, the wooden sides afford the cheapest and readiest means for connecting outside and inside borders. My Peach house is the outside one of a group of three divisions originally intended for Tomatoes, and the trees which are

covering the inside half of the Peach house send their roots through into the next compartment occupied by Tomatoes, and those on the outside portion of roof share a sloping border with early Strawberries. The association seems to agree with them. Ordinary deep land drains pass under the house at places, and this is all the drainage thought necessary. The preparation consisted merely in bastard trenching and mixing a little manure in the bottom spit, and the surface ground being also decidedly poor this was also manured as for vegetable crops, a sprinkling of half-inch bones being added. For two successive seasons Tomatoes in pots were fruited in this house, and as these were allowed to root out into the border, there was little likelihood of the soil proving too rich for the Peach trees. A heavier soil than I have to deal with would be benefited by a free addition of lime rubbish and "burn-bake," or charred garden refuse, soil, and ashes from a slow fire, and this material with a little fresh loam, short manure, and bone-meal is annually supplied to my border as a top-dressing prior to commencing forcing, such top-dressings serving to keep the roots active near the surface.

W. IGGULDEN.

CHRYSANTHEMUMS.

NOTES ON CHRYSANTHEMUMS.

THE present season, as far as this neighbourhood is concerned, has not been satisfactory for the growth of Chrysanthemums, the continued rains and dull days having brought about a sappy and hollow growth in the first stages. It is such gross growers as Mme. Carnot that are worst in such a season, and when cutting down the plants the stems were so hollow, that an ordinary slate pencil might very easily have been passed down them. The habit of this fine variety is not all that could be desired, for if at all well fed the extra strength often shows itself in a kind of multiplication of buds, and what promises to be a fine bloom splits itself up into scores of small ones. The same thing is occasionally seen in badly ripened plants of the incurved section, and an old variety, Cherub, was singularly subject to it. Unless much brighter and warmer weather sets in I shall look for poor flowers of the incurved section. Good blooms of these old favourites cannot be had without abundance of sunlight and heat during the growing season, and many of the older growers owed much of their success to suitable positions. West of England growers will be familiar with the fine flowers shown by an old amateur grower, Mr. J. Bayliss, whose plants, grown in a Pennant stone quarry on the side of a hill, were never large, but, owing to the radiation of sun-heat from the rocky sides, were always exceptionally well ripened. The Japanese section will stand more feeding; they are, in fact, much easier to grow, and consequently more popular, while for decoration their graceful flowers and great variety of colouring give them an unrivalled position among autumn and winter-flowering plants.

Among them now there is plenty of work required, for they are growing vigorously and need almost daily attention in removing lateral shoots, tying, and other cultural details. Insects, too, are abundant, earwigs being quite as active as usual notwithstanding the wet and cold nights. Green fly has given more trouble than usual, and one needs to be always on the look out. I find a little tobacco powder at once the simplest and most effective means of getting rid of this pest in the tender tops of the

plants, and use an insecticide in water for the lower leaves should any make their appearance there. On the hardened and ripened leaves below, these pests do little harm, but their presence is a guarantee of plenty of young broods attacking the tops.

After the plants are well established in their flowering pots I always syringe them daily with weak clarified soot water, and the value of this is not sufficiently realised by amateur growers. There is a certain and gradual improvement in the appearance of the plants when it is first used, the foliage taking on a deeper tint of green, while it is helpful in keeping down mildew and insects. Soot water at the roots, too, is one of the very best fertilisers early in the season. Used frequently in a weak state it promotes root action rather than hinders it, as so many manures do, and when soot at least a year old can be had, it may be lightly dusted over the foliage with advantage. Watering at the roots is an important item now, and one too frequently gone about in a careless style. Many of the finest varieties are easily injured by over-watering, Edwin Molyneux, Mrs. W. H. Lees, and Miss Dorothy Shea as instances. Growers with a light soil at command are in a relatively better position with these and other kinds than those who have a more adhesive soil to deal with; but in any case it is better to pass a doubtful plant for an hour or two and look them over often than to give water before it is really necessary. H.

Bury St. Edmunds.

DESTROYERS.

THE FRUIT TREE BEETLE.

(SCOLYTUS RUGULOSUS.)

SEVERAL complaints, according to a leaflet issued by the Board of Agriculture, have been received of injuries to Apple trees, which proved to be caused by the boring beetles known as Scolytus rugulosus. The tips of the smaller branches were almost honeycombed by the larvæ, many of which were found alive and active in the channels made by the insects. It seemed that the larvæ were more fond of the soft bark, as they were more frequently found there, than of the harder wood of the branches. Many of them, however, were in bark that was decaying or nearly dead, and it was not common to find them in healthy bark. There seems to be no doubt that this insect has a decided preference for sickly trees and parts of branches where there is the least flow of sap. The larvæ have been frequently found in the tips of shoots of trees injured by frost or other weather influences, as well as near scars from canker and knife cuts and knots. It is not clear that the beetle attacks perfectly healthy and vigorous trees, nor, on the other hand, that it does not attack such, and it is certain that the onslaught of these beetles upon a young tree that might be temporarily sickly from some other cause would prevent its recovery and hasten its destruction. The fruit tree beetle not only attacks Apple trees, but Pear, Plum, Cherry, and Peach trees are also frequently infested by it. The dying away of the ends of the twigs and smaller branches and the shrivelling up of the leaves are signs of infestation. On close inspection, many round holes, of which the diameter is hardly equal to that of an ordinary pin's head, will be seen in the bark of badly infested trees. These holes will be found to lead to the surface of the woody parts, upon which will be found channels or grooves, made lengthways up and down in

the bark, and between the bark and the wood; on either side of these are smaller channels, in which larvæ are ensconced.

LIFE HISTORY.—The female beetle may be seen flying towards the end of April. It bores holes in the bark, or rind, of the branches or twigs of trees, and forms channels as described above, about half an inch long, close to the wood, placing its white eggs with some regularity upon either side of these. Larvæ come from the eggs in a few days and begin to feed on the bark, making branch channels nearly at right angles with the main channel. At the end of these branch channels the larvæ make a small hollow, generally in the woody part, to form receptacles for pupation, in which the pupæ are lightly covered with frass. After pupation the beetles bore holes through the bark and escape. There are at least two generations of this insect during the year, and the winter is passed in the larval state, so that active injury is continued almost throughout the year. The beetle is barely one-tenth of an inch long and black in colour, except the ends of the wing covers, legs, and the much-clubbed antennæ, which are of a russet colour. The thorax and wing covers are much wrinkled and punctured. The larva is not quite one-tenth of an inch long when extended, it is milky white, without legs, and has a chestnut-coloured head furnished with strong black mandibles. The upper part of the body is considerably thicker than the lower part, and it lies in a curved position.

METHODS OF PREVENTION AND REMEDIES.—

Not much can be done against this insect in the way of prevention or remedy. All the branches and limbs that are infested should be cut off and burned during June before the beetles have escaped. Where a tree is badly infested in various places it should be cut down and burned during June, so that larvæ, pupæ, and beetles may be destroyed. In orchards, fruit plantations, and gardens where there is considerable infestation, it would answer to adopt the American recommendation to ring, or girdle, worthless trees that are either unfruitful or already decaying. This is done by cutting strips of bark round the trunks in the spring, and letting them remain until the following June, to serve as traps for the beetles, which will be attracted and lay eggs in it. The trees should then be cut down and burned during the ensuing June before any of the beetles escape from the colonies within. It is feared that the application of noxious compositions would be quite useless as a means of preventing the beetles from boring into trees, unless all the trees in an orchard or fruit plantation were similarly treated, which would be a difficult and costly process. When the beetles have once got into the bark no amount of syringing would affect them. In the case of gardens with two or three trees only, these might be syringed, or daubed over, with a very thick wash of an offensive nature, such as thick paraffin emulsion, before the leaves and buds showed, so as to prevent egg laying where an attack is feared. When there is decided infestation in the case of a few trees in a garden, it would pay to examine every branch carefully, and cut away and burn all those which have the typical holes. This beetle is destructive to fruit trees in the United States and in several European countries. In the United States it is kept down by parasites, species of Chalcididæ, one of which was identified as *Chiro-pachys colon*, and another was probably *Pteromalus maculatus*. The beetles and larvæ sent to the Board of Agriculture were kept in glass-topped boxes, and at least two species of Chalcididæ appeared from them.

FLOWER GARDEN.

GENTIANAS.

GENTIUS, King of Illyricum, the eastern boundary of the Adriatic, was taken prisoner by the Romans about a century and a half before the Christian era for encouraging pirates, and died in custody. He discovered that a certain plant was a very good tonic, and that plant has ever since been called *Gentiana*, after him. This plant is generally supposed to have been the tall, coarse alpine, common in mountainous districts in Central Europe, and known to botanists as *G. lutea*, a preparation of which is still in high repute as a medicine. The Roman naturalist, Pliny, however, tells us that the *Gentian* has leaves like an Ash tree,

or *G. nivalis*, it is at once obvious that the genus cannot be discussed collectively, but that each species must be dealt with separately. It can hardly be claimed that more than five species are in common cultivation in English gardens.

G. LUTEA is not very often seen, probably because it is not very attractive as an ornament, and not because there is anything difficult in its treatment, as it will grow in any strong and well-drained soil, and continue healthy without attention for many years. It grows more than a yard high, with stout plantain-shaped leaves and four or five close whorls of flowers of a dull yellow colour. It cannot be divided or transplanted when old, and must be raised from seed, which it ripens abundantly.

G. ACALIS, the common *Gentianella*, is known to everybody, but cannot be grown successfully

to it. In many of its native places it is probably frozen every night whilst in flower. The seedlings should be planted in trays, and the contents of the tray, when two or three years old, turned out entire in spring into the place they are to occupy permanently. If planted out in autumn the frosts of winter push the plants out of the ground.

G. ASCELEPIADEA is very robust and lasting in *Edge Garden*, in which *G. acalis* is hardly a success. It is better to raise it from seed than to divide old plants, which take long to recover, and do better when left alone, growing in sheltered and well-drained borders 2 feet high and as much across. There is a variety with dingy white flowers, growing stronger than the type but less ornamental.

G. SEPTEMFIDA, the subject of the accompanying illustration, is the most easily cultivated species except in dry, sandy soils. The name, which means seven clefts, has been explained as referring to the scales between the divisions of the corolla, which are fimbriated, and may sometimes be found to have seven points; others allege that it is because the flowers in a cluster are often even in number, but these are poor apologies for an inept name. It is evident to anyone who reads the description of the plant given by the German botanist Pallas, who discovered it more than a century ago, that the specimen from which he took his characters was abnormal, having seven divisions in the corolla instead of the usual five. The words of Pallas are, "Corollis septemfidis, quinquefidis quo laciniis intercalariis ciliatis" (having the inserted scales fringed). The plant is figured in the *Botanical Magazine*, t. 1229 (A.D. 1810), and Sims, who wrote the letterpress for that volume, rightly says that the corolla is divided "for the most part into five, sometimes six, rarely seven, laciniæ." The illustration shows two or three with six, but I recognise none with seven, though amongst the many plants in my garden some are easily found with seven. This desirable species ripens seed plentifully, but grows slowly and lives for many years. The height varies from 3 inches or 4 inches to 18 inches. A dwarf strain may easily be obtained, as the seedlings follow the stature of the parents, and the low growth is neater than the taller.

Edge Hall, Malpas. C. WOLLEY-DOD.

Gentiana septemfida in Rev. C. Wolley-Dod's garden at Edge Hall, Malpas. From a photograph by Miss Wolley-Dod.

and Dioscorides, who wrote a Greek work on medicinal plants about the same time, says it has leaves like a Walnut tree. These statements are not true of the yellow *Gentian*, but both Pliny and Dioscorides described many plants about which they knew little or nothing, and, in spite of their statements, it is probable that this type of the genus is the plant originally named after King *Gentius*.

The genus *Gentiana* is a very large one. The names and synonyms of the species occupy nearly twelve columns of fifty names each in "Index Kewensis," and perhaps there are over 200 good species known to botany. But the number of these in common cultivation is comparatively very small, and when we consider the vast interval in stature and habit between *G. lutea*, the type, and such dwarfs as *G. verna*

in every garden: yet those fortunate people in whose gardens it grows well without difficulty are apt to look with pity, not without some contempt, on others who cannot grow what seems to themselves so easy a plant. And yet they cannot tell the reason why their friends fail, and cannot teach them how to succeed. *Gentianella* is an excellent test of a good and well-drained garden soil, and where the sub-soil is cold and wet, and the atmosphere tainted with stagnant damp evaporating from the ground, this mountain plant is one of the first to show the unfavourable conditions, which little can be done to remedy.

G. VERNA requires made soil to a depth of a foot or more, and even with that there are few gardens in which it will last more than four or five years without being renewed from seed or from the nursery. It wants well watering in dry weather through summer, and warm, wet winters are unfavourable

Pentstemon George Fisher.—This is a very fine variety. The spikes are large and the individual flowers are as large as those of a medium-sized *Gloxinia*, much more open in front than in the majority of kinds. The colour externally is a very bright rose, almost crimson, while the throat is pure white, the margin bright rose. It is one of the best of a number of named kinds I grow, and a fine garden plant in every way. The poor strains of flowers often sold prevent many people raising these plants from seed, otherwise a useful stock of plants is soon obtained in this way.—H.

Rock Roses.—Common and fleeting as are the different varieties of *Helianthemum*, they are charming while they last, one sunny day being the whole life of thousands of the bright little blossoms. At the foot of rockeries or the front of herbaceous borders they have a beautiful effect while in flower, and the loose rambling tufts or foliage are not unsightly at any time. The colour of the many forms of *H. vulgare* differs considerably, from the yellow of the type to pure white, while many shades of red may be found. One sent out under the formidable name of *Red Dragon* makes a very pretty show just now.

Herbaceous Phloxes.—Looking over a big breadth and a very fine representative collection of hardy *Phloxes* that were lifted and transplanted last winter into fresh soil, and noting how great generally was the failure on the part of the plants to make good growth—indeed, not a few had died and others were wretchedly poor—I could but think how great was the mistake made in thus troubling to lift, divide, and replant old stools when the taking off of a few shoots from the crowns of the stools in March, putting them into

sandy soil in pots, and standing them for a few weeks in a warm house or frame to root would have given a great abundance of stout plants to bloom finely the same season. There would have been no failure in such case. The young plants could have been put out singly, or in clumps of three or four if so desired. It does not seem to be understood that each spring a shoot from any herbaceous plant seeks to make its own roots, and thus find its own separate subsistence. That the summer shoot cannot do when it is one of many growing from out a thick cluster of roots that already occupy the soil and subsist upon it. In such case no wonder that annual growths become weaker yearly. Thus with Phloxes. If these rooted cuttings be planted out singly, they are in the season invariably far stouter, more fully leaved, and, because they have ample light and air, much dwarfer, yet carry very much finer heads of bloom. Such plants will do very well the second year if the summer shoots be thinned to a few, but these will be taller than were those of the first year. Those who have good Phloxes should not fail to propagate every year.—A. D.

CUP-SHAPED LILIES.

By Mr. Baker the different Lilies are divided into five groups, to which distinctive names have been given. The sub-genus *Isotirion*, which is characterised by erect flowers more or less cup-shaped, does not include a very large number of species, but amongst them are some of the most useful Lilies that we have for the open border as well as some of the earliest. One of the best known of this group is *Lilium elegans*, or *Thunbergianum*, which is quite a dwarf Lily, though some of the varieties are taller than others. One of the dwarfiest of all is *alutaceum*, whose heads of yellowish buff blossoms are borne on stems little more than 6 inches high. Another variety, *Prince of Orange*, is much in the same way, but the flowers are of a richer yellow. A very prominent feature of *L. elegans* is the great range of colour that occurs in the different varieties; thus, besides those just mentioned we have various shades of red, orange-red, and crimson, to the deep blackish maroon flowers of *Horsmanii*, one of the most striking by reason of its colour, as well as one of the rarest of all the varieties of *L. elegans*. Other distinctions occur in the varieties of this Lily; thus *staminosum* produces double blossoms, while though *L. elegans* is regarded as an early Lily, and some of the varieties are among the very earliest, yet one, *venustum*, is much later in flowering than any of the others. All of those just mentioned do well in any ordinary garden soil, particularly if it has a basis of sandy loam. They may also be successfully flowered in pots as well as in the open border. One great merit possessed by them is the fact that they can be depended upon to bloom well the first season after planting, a remark that also applies to most of these cup-flowered Lilies. In the open ground they may be planted in various ways, one method very popular of late being to associate them with low-growing shrubs, while if a Lily border is formed they make a suitable foreground to the larger growing species. In any case these small-growing kinds must not be dotted indiscriminately here and there, but enough of each kind should be planted to form a bold clump or clumps, as it is only in this way that the beauty and distinctive characters of the several varieties can be seen. Next in popularity to *L. elegans* comes *L. umbellatum*, sometimes known as *L. davuricum*, of which there are several forms in cultivation. They are taller growers than most of the varieties of *L. elegans* and the range in colour is not nearly so great, consisting principally of various shades of orange-red. They form first-rate subjects for the outside border and are thoroughly hardy. The next of this group to be mentioned is the old orange Lily (*L. eroceum*), which is, I think, entitled to a place among the finest of all Lilies. It is somewhat later in blooming than any of the preceding, and though grand masses of its warm, orange-coloured flowers may

be frequently seen in cottage gardens, it is, strangely enough, not readily obtained from dealers, for frequently a form of *L. umbellatum* is made to do duty for it. A well-known yet scarce Lily of this section is *L. bulbiferum*, characterised by the production of small bulbils in the axils of the leaves, as in the case of *L. tigrinum* and *L. sulphureum*. *L. bulbiferum* grows as a rule from 3 feet to 4 feet high, while the flowers, instead of being arranged in a close, compact head, as in most forms of *L. umbellatum*, are disposed rather in a deltoid raceme. The flowers are borne on long stalks, so that each individual bloom is almost, if not quite, clear of its neighbour, and in a vigorous specimen the head of flowers forms quite a broad pyramid. The colour of the flower is a warm orange-red—a very pleasing and attractive tint. *L. bulbiferum*, which is a native of Central Europe, blooms in June at about the same time as the forms of *L. umbellatum*, but its flowers last much longer than any of them. Another species belonging to the *Isotirion* group is the Japanese *L. Batemannii*, whose warm apricot-coloured flowers are borne, as a rule, in the early part of July. It is a pretty Lily, but is rather more fastidious than most of this section. A North American species—*L. philadelphicum*—is totally distinct from any other of this class. The leaves of this are usually arranged in whorls, while the flowers, which are large for the slender stem, are yellow, tipped with red, and more or less spotted with maroon. This does, as a rule, better in a fairly moist soil containing a good proportion of peat than it does in any other. It is an old species, but not often seen. *L. Wallacei*, which was figured in *THE GARDEN*, January 30, 1897, is another of this group. In general appearance it bears a considerable resemblance to some forms of *L. elegans*, but its bright apricot-coloured flowers are rarely borne till the early part of August, while it increases by division of the bulbs more rapidly than any other Lily, though the Japanese *L. concolor* behaves much in the same way. It is certainly a very beautiful Lily, and perpetuates the name of one of the most ardent lovers of this class of plants, a name well known to all cultivators of Lilies. Two Japanese forms, *L. Coridion* and *L. concolor*, as well as the Siberian *L. pulchellum*, are pretty little Lilies of this section, the first-named bearing yellow and the two others bright crimson blossoms. They are all charming little Lilies, but far more particular in their cultural requirements than most of those previously mentioned. A well-drained, yet not a parched-up soil, of loam, peat and sand, seems to suit them best. H. P.

TUFTED PANSIES.

THE advent and subsequent rapid development of the taste for the massing or bedding in flower gardening which evoked so much enthusiasm among gardeners and amateurs some forty or fifty years ago will well be remembered by those of the present day who helped in the management of the many gardens where this system was so well and so largely carried out. So much, indeed, in my own recollection did this develop into a craze, that there seemed to be a danger that the grand old herbaceous and alpine plants, the pride of our fathers and the glory of their gardens, were doomed either to extinction, or at the best only to be preserved in botanical collections, while gardeners themselves, trained more to appreciate the merits and distinctions of the more fashionable so-called bedding plants, seemed to forget that the hardy perennials were as decorative and as worthy of attention as they used to be. There are, indeed, obvious signs of a marked change in this direction, and bedding, as formerly practised with tender showy things, will continue so long as there is an appreciation of gaudy coloured flower beds. As a natural result of the new fashion in flower gardening, plants with continuous flowering properties, distinct and striking colours, and compact habit of growth grew rapidly in favour. Geraniums, *Calceolarias*, *Verbenas*, and other flowers of similar character were

largely employed, any new acquisition being hailed with delight. Pansies, too, which as florists' flowers had their hosts of admirers, were duly pressed into the service, but with all their beauty in spring and early summer it was found that, notwithstanding their dwarf growth, they could not be relied upon to maintain their flowering in light, dry soils and very dry, parching, sunny weather in July and August; hence blanks appeared in the borders and beds at the very season when perfection was most desired. A perpetual flowering Pansy with richly coloured flowers equal in habit to the existing sorts, and a constitution strong enough to bear, if not enjoy, the parching ordeal of July, was much to be wished for, and sure to be cordially welcomed by those interested in the beauty of the flower garden. Some thirty years ago it occurred to Mr. James Grieve, then manager to Messrs. Dicksons and Co., of Edinburgh, and now head of the nursery firm of James Grieve and Sons, Red Braes, Edinburgh, that the result could be obtained by crossing the existing Pansies with some of the wild native species, and, acting on this idea, he at once put those of the neighbourhood under cultivation, forming the foundation of the grand race of Tufted Pansies which now are such prominent objects in our flower gardens, and indispensable wherever a gaudy show of colour is desired. Innumerable varieties have since been added both by himself and others of like tastes. It may be added that many of his first trophies are with us still—among these, *Golden Gem*, *Grievei*, both capital yellows, and both with the blood of *V. canina* in their veins, with many others, the result of hybridising *V. tricolor*; while from the alpine *amena* have sprung some of the various shades of blue, lilac, and purple, so much and deservedly admired.

On a recent visit to the Pansy ground of the firm I found 160 varieties in cultivation, while thousands of seedlings are on their trial; and such is the demand, that nearly 100,000 are required for the spring supply. From such a large and varied collection it seemed very difficult to select a moderate number of really distinct and striking sorts, and I confine myself to a few as probably the most desirable, at least to those who have limited space:—

YELLOW.—*Bullion*, *Mary Gilbert*, *Brilliant*, *Lady McDonald*, *Pembroke*.

WHITE.—*Countess of Hopetoun*, *Pilgrig Park*, *Marchioness*, *Pencaitland*, *Beautiful Snow*, *Christiana*.

BLUE.—*Blue King*, *Blue Gown*, *True Blue*, *Magnificent*.

PURPLE.—*Archie Grant*, *Holyrood*.

LILAC.—*Lilacina*, *Peach Blossom*, *Duchess of Sutherland*.

BRONZE.—*Joseph*.

OMEGA.

Brompton Stocks.—Some forty years since my now deceased elder brother, W. Dean, took occasion in one of the gardening papers to show the error then, and apparently still, held that the double flowers of Stocks contain pollen. I have noticed that at page 5 of the present volume a writer, referring to the single nature of Brompton Stock flowers, expresses the belief that seasons or weather may materially affect the transference of pollen from double to single flowers; hence the lack of doubles in the progeny. But if anyone will take the trouble to examine a double Stock flower, especially of any Brompton variety, he will find that there is not the least evidence of any organs of fertility in these. It was in old days a recognised axiom that singles would not produce doubles by seed unless the two when in bloom were growing side by side. It was to disprove the incorrectness of that tradition the discussion referred to originated. Why good double strains of Stocks should revert to singles is very difficult to understand, but their doing so is nothing new. I have found it to be the case with scarlet and white Bromptons, with the branching Queens, and with summer Stocks. It must not be forgotten that the conversion of the true flower, with its

four or, at the most, five petals, and its organs of fertility into a barren floral branch, is but a sport, and nothing is easier than its reversion. It may be, in fact, but an effort of Nature to come back

they were stronger than he had ever seen them, as he had been feeding them, and that as long as no rich food was given there was no disease. I am convinced it is a mistake to give this Lily high living. In some of the cottage gardens in a village near here they bloom splendidly and never have disease. The plants never have any food, and have been in the same soil for the last eight or ten years.—DORSET.

Gentiana asclepiadea. (See p. 37.)

to its pristine habit of seed-production. It is also possible that liberal cultivation tends materially to de-troy that doubling tendency which seems to be largely created in Stocks by artificial methods of culture, especially in pots and under glass.—A. D.

Four good Tufted Pansies.

—All will agree that Tufted Pansies are a most important class of hardy plants. Many of the old kinds hold their own now, and I doubt if ever they will be beaten from a free blooming point of view. Another recommendation many of the old kinds have is that they are decided in colour. The following are my favourites: Archibald Grant is a grand indigo-blue, the flowers large, and especially when the plants are young and growing in rich soil. With me this does not bloom as long as Ardwell Gem, which is very dwarf and very free blooming. As a white I cannot find any colour to surpass Countess of Hopetoun. It is a compact in habit and keeps up a good succession of bloom. Those who want an attractive parti-coloured kind should grow Countess of Kintore. It is a deep blue-purple with broad edge of white. I have grown these kinds largely for upwards of a dozen years and see no reason for changing.—D.

The Madonna Lily diseased.—This disease is very troublesome, and does not seem as if ever it will be exterminated. Mr. Burrell makes some remarks anent the disease, and he is under the impression that it is atmospheric. In this I am at one with him. But whether this is brought on by giving the plants too much rich food, and thereby producing a soft stem and leafage, I cannot say. Everyone knows only too well that many plants and animals are predisposed to some forms of disease when they are gorged by rich food. At the end of June I was looking over a villa garden in Chard, where I have seen some of the finest flowers of this Lily. They are growing at the foot of a south wall, and to my surprise they were one mass of disease. I remarked to the owner as to their condition, and he said that

THE CLEMATISES.

(Continued from page 348.)

SECTION II.—VITICELLE.

The Viticelle (*Viticella*, a little vine) are so called because, for the most part, they are climbing plants, like the Vine. The stems are branching, the leaves entire and glaucous, or nearly so, and the single flowers are borne on long peduncles in racemes or spikes. Larger than those of the paniculate, the flowers are medium sized, blue generally or purple in colour, and rarely white. The sepals, four in number, are when in bloom displayed crosswise.

There are four distinct types of Viticelle: (1) *Viticella*, (2) *Viorna* (*urnigera*), (3) *integrifolia*, and (4) *tubulosa*.

1. VITICELLA.

These are the Viticellas proper, high-climbing plants, the type of which has flowers with four crossed sepals. In this group I place *C. revoluta*, *crispa*, *campaniflora*, and *divaricata*. The more natural way would be to make one distinct group of these, with *C. campaniflora* for the type, and give them one common name, as *C. campaniflora*. The Viticella forms differ from the *Viorna* and *urnigera* forms in the flowers, which, instead of being pitcher-shaped, are cylindrical, the sepals being also revolute.

1. C. VITICELLA (Linn.)—This is the type of the section. It was formerly known as the "blue" Clematis, under which name it is described in the "Encyclopedie Methodique" and elsewhere. Its place of origin is Southern Europe, Spain, and Italy, but its geographical area extends even as far as Asia Minor and Persia ("Index Kewensis"). Thus the blue Clematis belongs, among the Viticellas, to the Mediterranean region, like *C. Flammula* amongst the *C. paniculate*. Its first introduction to France took place in 1569, and it soon became a favourite in gardens, where its blue flowers with their sepals, four in number and crossed, caused quite a sensation when placed alongside the smaller white flowers of *C. Flammula*; and as a climbing plant it was quite as well fitted to the adornment of trellises and arbours. Later *C. Viticella* was to play, as a seed-bearer, an important part in the production of the large-flowered Clematis,

not to mention the use which was to be made of the roots in grafting. *C. Viticella* has a number of varieties bearing purple, red, rose-coloured, violet, white, and double blue flowers. There is a dwarf species likewise in cultivation (*Viticella nana*), and, in late years, several interesting hybrids have been obtained, of which I shall speak in due course. The old double variety (*Viticella plena*) is still in cultivation. It is a pale blue flower with a tinge of red; the four large sepals fall off, leaving the centre of the flower to continue long in bloom with a great number of small petaloid sepals, which in falling strew the ground. These are produced at the centre, which is sometimes profliferous, as in the case of *C. florida plena*. *C. Viticella* is a charming Clematis, and from the facility with which it ripens its seeds it has proved of great value to the hybridiser. By using the purple forms of *C. Viticella* of late years the magnificent large and red flowers of *C. Mme. Furtado Heine* and *Mme. Ed. Andre* have been obtained from *C. Jackmani azurea* and *lanuginosa*.

2. C. REVOLUTA.—This is not a white variety of *C. Viticella*, but a distinct species with smaller, white, and revolute flowers, the leaves also being distinct, larger, and of a brighter green. I have cultivated it along with a Clematis which came to me under the names of *parviflora* and *capaneaflora*, and is a mere variety scarcely to be distinguished from *revoluta* by its flowers being slightly tinged with violet, or lilac, on the outside. Moreover, *C. parviflora*, although described as a species by Candolle, is commonly considered the same as *C. revoluta*.

3. C. CRISPA.—This Clematis is of North American origin. Brought to France in 1726, it never became popular, and has been confused with other and allied species. I believe it came to me as *C. Shillingi*, a climbing species with rose purple and fairly large flowers, and the sepals connivent at the base and wrinkled and curling at the edges.

4. C. CAMPANIFLORA (Brot.) (the bell-flowered Clematis) I have long cultivated. It is allied to the preceding, and through its flowers with their half-connivent sepals it forms a link with the *urnigera* of the next group. It is a charming species, with smooth, deep green leaves and graceful flowers of delicate purple-blue colour. It comes from Portugal, and has been in cultivation in France since 1810. Candolle classes it with *C. Viticella* on account of its seed-heads, which are bare and beardless.

5. C. DIVARICATA (Jacq.)—Under this name I saw in the museum at Paris a quite distinct species, which came into commerce under the name of *C. Camuseti*. Its flowers are fairly large, violet

Gentiana acutulis. (See p. 37.)

in colour, and half displayed. It is a climber, but subfrutescent, and rises to a height of a little over 6 feet.

2. VIORNA (URNIGERA).

I place the *urnigera* apart from the Viticelle proper. They form with *C. Pitcheri* and *C. coc-*

cinea a distinct race, characterised by little bell or rather pitcher-shaped flowers. I describe here five species, viz., (1) *C. Viorna*, (2) *C. Pitcheri*, (3) *C. coccinea*, (4) *C. reticulata*, (5) *C. cylindrica*.

1. *C. VIORNA* (Linn.).—This is not to be confused with our own hedge Clematis (*C. Vitalba*). It originally came from Northern America, Virginia, and Carolina. It is the oldest known type among the urnigeræ (*C. urnigera*, Spack.), having been known in Europe since 1730. *Viorna*, like the other species of this group, is classed among the *Viticella*, notwithstanding that these have their carpels furnished with feathery tufts. It is characterised by its upward-growing stem and the pitcher-shaped flowers, purple on the outside and yellow within, the sepals being thick and leathery, so to speak, and connivent for half their length.

2. *C. PITCHERI* (Torrey and Gray).—*C. Pitcheri* flourishes in the United States of America from Illinois to Mexico. It is closely allied to *Viorna* through its pitcher-shaped violet or violet-grey flowers, as I recently saw on examining the buds of a specimen in cultivation in the Naval Botanic Gardens at Brest. The leaves are rounded and of a glaucous, almost bluish, green. The four thick, fleshy sepals, borne upon a long coloured pedicel, are abruptly contracted; the open and slightly revolute divisions are a yellow-green within, leaving the stamens exposed to view. *C. Pitcheri* begins to flower in May.

3. *C. COCCINEA* (Engelman), *C. TEXENSIS* (Buckley).—Professor Buckley found this on the banks of rivers in Texas. Its flowers, which are larger than those of *C. Pitcheri*, are of a vermilion-carmine on the outside and yellowish within. These two forms of *C. urnigera* have been intercrossed by MM. Morel, of Lyons, Paillet, of Chateau (Seine), Otto Fröbel, of Zurich, and the result has been the production of novelties possessing a habit and flowers of remarkable diversity.

4. *C. RETICULATA* (Walt.).—*C. reticulata*, or pocket flower Clematis, is allied to *C. Viorna*, and, like it, originated in Carolina and Georgia. It was introduced into Europe in 1812.

5. *C. CYLINDRICA* (Sims).—This blooms in June, and is apparently a link between the *Viorna* and *integrifolia* groups. It is distinguished by its flowers of a fine bright blue and by its crumpled sepals arranged cylindrically. Hence the name. Like all species of this group, *cylindrica* belongs to Northern America—Pennsylvania and Carolina—and was brought to Europe in 1802.

3. INTEGRIFOLIA.

This group comprises only a small number of species. Candolle in his "Prodromus" only describes four—*C. integrifolia*, *ochroleuca*, *ovata*, and *gentianoides*. The last-named, which is a New Holland species, came to me from the Muséum at Paris, and I classed it among the *aristata* group, or Australian Clematises. The yellow-flowered Clematis (*ochroleuca*, Ait.) appears as one of those in cultivation in European gardens in Jacques' Manual, 1845. I have no personal knowledge of it. Like *C. ovata* (Pursh.), its home is North America. Both are distinguished from *C. integrifolia* by their oval-shaped leaves.

C. INTEGRIFOLIA (Linn.).—This is the oldest known species (1596), and came originally from the Pyrenees, Hungary, Siberia, and Tartary, that is to say, Southern Europe and Northern Asia, two very different geographical areas from the point of view of climate, a strange and rather exceptional fact. *C. integrifolia* is perennial like *C. erecta*, and has the leaves entire, dark green, oval-shaped, and slender. The handsome drooping dark blue flowers are borne upon one-flowered peduncles. It is cultivated in many gardens, and presents a certain number of varieties, notably—(1) a variety the leaves of which are sometimes entire and sometimes divided (*C. integrifolia* var. *diversifolia*); (2) a handsome hybrid known

to commerce as *C. integrifolia* Durandi. This last is higher than the species, has larger flowers, and a long and recurring bloom. *C. integrifolia* has been used for crossing with other species, notably *C. Viticella*, whereby is derived the hybrid variety Hendersoni, which M. Decaisne has classed as a species under the name of *C. Eriostemon*. I had a correspondence on the subject, in the course of which I related my observations as regards this sub-frutescent, non-climbing Clematis, which I consider a true hybrid, of which the feathery seed-heads are nearly always sterile.

4. TUBULOSA.

This forms an extremely natural group, characterised by strong, straight, and generally low stems, sub-frutescent and very leafy, the leaves being large, trilobed, and thick, the flowers small and in whorled spikes or cymes, with revolute sepals like those of the Hyacinth. About 1880 M. Decaisne and, subsequently, M. Lavallée wrote a monograph on this little family of Asiatic Clematises, which belong rather to the realm of botany than to horticulture. M. Decaisne described eight species: *C. tubulosa*, *Davidiana*, *Hookeri*, *Stans*, *Kousabotan*, *Savatieri*, and *Tatarinowi*. I shall only speak of the three first species, which I know personally.

1. *C. TUBULOSA* (Turck.).—This Clematis originally came from China and Mongolia (*C. tubulosa* mongolica), from whence it was introduced into Europe in 1837 by the Russian botanist Turckzaninow. It is perennial, or rather sub-frutescent, with thick upright stems from 16 inches to 24 inches in height. The leaves are dark green, thick, and tough. The flowers are on a whorl and bell-shaped, the colour azure-blue, of a deeper shade without than within. I have long cultivated this spreading Clematis, and have found it quite hardy and interesting from its distinct growth and September bloom.

2. *C. DAVIDIANA*.—This species was raised from seed sent from China to the Muséum at Paris by the Abbé David. It is allied to the preceding by its foliage and its indigo-blue flowers in whorls.

3. *C. HOOKERI* (Dne.).—According to Hooker this is merely a variety of *C. tubulosa*.

C. SAVATIERI is the only branching form of *C. tubulosa*, and never exceeds 4 yards or 5 yards in height.—DR. JULES DE BELE, in *Bulletin d'Horticulture de la Sarthe*.

(To be continued.)

SOME USEFUL SUMMER-FLOWERING CREEPERS.

WHEN recently at Reading I was much interested in what might be termed a trial of summer-flowering climbers. The whole of them had been raised from seeds sown in the spring and planted out to flower. Amateurs with limited room and means are frequently found inquiring what can be grown for covering bare places or for training up pillars. In the case of this trial a good portion of a south wall had been given up to the purpose. The various plants used had been planted long enough to have made a good start and some were already in flower. About 2 yards of wall are given to each; so a good and reliable test is afforded.

There was of course the Canary Creeper, and as there was ample space of wall, two or three patches had been planted alternating with other subjects. The plants had made a free growth and were just coming into bloom. Like the Mignonette and Sweet Pea, this charming species must find a place in every garden, for it is indispensable to the summer display. There was Lear's Convolvulus (*Ipomœa Leari*), which, though classed among stove climbers, will yet with proper management flower well in the open air if it can have a warm sunny position and good soil. It was making a free growth despite storms and cold nights. A portion was given up to the major Convolvulus, of which there are several handsome varieties. This is frequently seen in gardens, but is not nearly so well cultivated as it deserves

to be; as a consequence the blossoms are small and the bloom short-lived. The old *Mina lobata*, now to be known as *Ipomœa versicolor*, was here also. It is well named, because the blossoms, at first rosy crimson, change to orange and pale yellow. As it is not quite hardy it should not be put out in the open until warm weather is assured. *Maurandya Barclayana* was among them, and also another well-known species, *M. scandens*, formerly classed as *Lophospermum*. Both these can be raised from seeds readily enough for this purpose. They are half-hardy, bloom freely and for a considerable time. Both are very useful in the garden, and should have good cultivation. Then there is the Chilean *Loasa lateritia*, or, according to the seed catalogues, *aurantiaca*. This produces large dull red, attractive flowers. It can be raised from seeds without difficulty, and is highly effective when at its best. *Ecermocarpos* (*Calampelis*) *scaber* is also indispensable. This is a hardy perennial in the south, but of doubtful hardiness in the north, except in favourable localities. A little protection to the roots during winter can be afforded without much trouble. It is a vigorous grower when established, the flowers are freely produced in clusters, and, being gold and red, are very showy. It is a fine old and very popular climber, and can be raised from seeds sown in March. That form of the Hop known as *Humulus japonicus* and its variegated variety were also here, hardy, free-growing plants, which soon cover a considerable space. The variegation on the variegated form is distinct and striking. Lastly came a patch of a bright crimson form of *Tropœolum lobbianum*, which was blooming freely and helping the variety found in the collection.

As so many of the foregoing can be raised from seeds, they are adapted to those with limited means.

R. D.

NOTES AND QUESTIONS.—FLOWER.

Crepis sibirica.—The shade of colour given to this plant in a recent issue was due to a clerical error, and is as stated originally by Mr. Wolley-Dod.—E. J.

Double tuberous Begonias.—I have eight large beds planted out from seed saved from the finest and most erect *Camellia*-shaped blooms. The great point when selecting flowers to work from is to see that no drooping-habited varieties are used. My plan is to decide first shape, then colour and habit.—W. BAYLOR HARTLAND, *Ard-Cairn, Cork*.

Nemesia strumosa Suttoni.—A large patch of this half-hardy annual I lately saw was very effective. This annual is not so suitable for growing in the form of individual plants as in a mass, therefore a large patch should be somewhat thickly sown, the result being a dense head of striking bloom. It is an annual that possesses a marked individuality of colour, and, though it loses its foliage quickly, the loss is not so noticeable when it is sown thickly.—R. D.

Lathyrus cœruleus.—I am employing the modern but incorrect term "cœruleus" to indicate the beautiful blue form of *Lathyrus sativus*. It is found in some catalogues under the name of *azureus*, or as Lord Anson's blue Pea. We have few annuals which give such a charming hue of blue as this Pea, but it possesses the fatal habit of some of the perennial Peas—the flowers speedily burn under the action of the sun. This Pea should be sown in the autumn and kept in safety through the winter to flower in spring to see it in all its beauty.—R. D.

Blue Primroses.—It would appear that the Oakwood blue strain of Primrose comes very fairly true from seeds. Judging from the naturally sportive nature of this flower, I was of opinion that not more than 2 per cent. of the seedlings would produce flowers of a true blue shade. I have seen several lots of plants this spring raised from purchased seeds, the produce being really satisfactory. It would appear likely, therefore, that in time quite 90 per cent. will come true. These blue Primroses are so distinct that they

must eventually find their way into most gardens.—J. C. B.

Iris caroliniana.—Mr. Ley's description is correct as far as it goes, and his plant is part of the original find. Mr. Baker's description of this species needs revision. It may be botanically near *I. versicolor*, but from a garden point of view it is a very distinct plant. It wanders, or pushes its growth further at the roots than *I. versicolor*, but like that species seems as contented in dry, still soil as in brackish water where sometimes found. *I. caroliniana* seems to be rather uncommon, was found first near Newbern, N.C., but has been lately discovered as far north as Southern New Jersey.—J. N. GERKARD, *Elizabeth, New Jersey.*

ROSE GARDEN.

ROSES IN THE GARDEN.

APART from growing fine specimen blooms, there is a great field open to lovers of Roses grown in various ways simply as beautiful garden plants, and now in their rich profusion no one will deery their claim to universal popularity. Large old plants of Gloire de Dijon and other nearly related Teas, also Cheshunt Hybrid, William Allen Richardson, and some of the older Hybrid Perpetuals, as General Jacqueminot, Alfred Colomb, and others equally well known, have been most beautiful with me, and the same is true of the pink Moss and Celine Forestier, which planted side by side flower about the same time and form a fine contrast to each other. Paul's Carmine Pillar was the first Rose to open, its rich colour and free-flowering nature making it a great favourite. Crimson Rambler will follow it closely, but though I am willing to admit this makes a fine show, it is certainly less beautiful in the open than under glass owing to the peculiar tint of the foliage. The copper and yellow Austrian Briers and the Penzance Sweet Briers, such as Lord Penzance, Meg Merrilies, and others, are showy and sweet, while the delicate flowers of the rugosa type are just at their best. There are a freedom and grace about these single and semi-double Roses that are lacking in the very double kinds, and though such as Belle Lyonnaise and Climbing Souvenir de la Malmaison have scores of buds upon them, the almost continuous rain has prevented their opening freely. The latter, as I have it here, is a fine climber, the flowers deeper in colour than in the old variety. Climbing Captain Christy, on the other hand, is a fine summer Rose, and very beautiful in its pale flesh tints. U.

Rose Leda (Damask).—It must be because it is not known that this pretty old Rose is so seldom seen. Years ago it was largely grown, but the introductions of the last twenty years have almost crowded out these old-fashioned kinds. Very few would refrain from adding Leda to their collection if they were to see it when well grown. Its flowers are of the peculiar crumpled form often seen in these old-fashioned sorts. The colour is bluish-pink, and the petals are margined with rich lake. We have no prettier Rose in all the old-fashioned tribe than this, and it deserves a better fate.

Polyantha Roses as dwarf standards. These excellent miniature Roses, when budded upon hedge Briers from 12 inches to 18 inches high, make most lovely objects for standing singly upon the lawn or for planting in the centre of beds of this class. Perle d'Or when thus grown is charming—indeed, all the tribe would be suitable. Mme. E. A. Nolte, Gloire des Polyantha, Perle des Rouges, Anna Marie de Montravel, Mosella, and Blanche Rebatel should be given a

trial in this way, and I am sure the desire would be to increase the number. It is so usual to see these Roses recommended for edgings to Rose beds, that one is apt to overlook the fact that there are other ways of making them useful.—P.

Rose Ma Surprise.—This was raised by M. Guillot and was introduced about twenty-five years ago. It is undoubtedly the result of a cross between the Teas or Noisettes and Rosa microphylla, for although we have a suspicion of the peculiar Beech nut-like calyx of the type, the flowers are as refined as those of any Tea Rose and sweetly scented. They are also of good size, quite 4 inches in diameter when expanded, double, and of a beautiful ivory-white shade, with salmon and peach-coloured centre. It is a good autumnal variety and grows with remarkable vigour, the growths greatly resembling those of the Teas. There is no variety among these latter of the same mixture of colours, and I believe it would become popular if more widely distributed.—P.

Rose Domestille Bear (Gallica).—A striped Rose of the perfect globular form of an Alfred Colomb is an acquisition. It is, of course, not so large as this grand variety, certainly not more than one-third the size, but large striped Roses are not wanted. The markings in this variety seem so refined; there is none of the garishness of a Rosa Mundi about it, which to some individuals is anything but pleasing. The colour of Domestille Bear is a delicate ivory-white, striped and splashed somewhat irregularly with clear rosy pink. It flowers freely and is a good grower, forming an interesting pillar variety. It is needless to add that such a Rose well repays anyone who gives it a little more consideration as regards feeding with liquid manure than is usually afforded these summer Roses.

Rosa fimbriata (hybrid rugosa).—One would take its flowers to be those of a finely-grown Dianthus were it not for the foliage. Its petals are not very numerous; usually about four rows compose the flower, but each petal is beautifully fimbriated, which is much accentuated by the edges of each one slightly turning upward. The outer row is almost pure white in colour, but the remainder are a delicate blush. Surrounding the stamens are three or four imperfect florets of a rich carmine-pink, giving a most artistic finish to a very uncommon Rose. It is not so free-flowering as many of the *R. rugosa* forms, but no doubt plants of it trained in pillar form would yield a larger quantity of blossom. Its foliage is a refreshing bright green and almost oval in form. It is said to be a cross between *Rosa rugosa* and the Tea Rose Mme. Alfred Carrière, and it certainly exhibits much of the latter variety in its lovely foliage.

Combination of early-flowering Roses.—For all who can afford the space, large masses of one variety of Rose are always best, but where accommodation is limited, pretty effects may be secured by judiciously combining those kinds that flower simultaneously. As the centre to a good-sized bed, I would suggest about three or four extra strong plants of Carmine Pillar trained in pillar form, around these a circle of the hybrid Sweet Brier Amy Robsart, followed by circles respectively of hybrid Sweet Briers Anne of Geierstein and Lady Penzance, with another ring of the double white Scotch Rose, followed by yet another of *Rosa ferruginea* (syn., *rubifolia*), which would give an interesting band of coloured foliage if well cultivated. To complete the arrangement, a band of the Austrian Brier Harrisoni, followed by an edging of miniature Provence de Meaux or Spong might be used. If the size of plant be regulated when planting according to its position in the bed, a pretty, interesting, and effective, almost conical, mass of blossom would enliven the garden during the early days of June.

Rose Caroline Testout.—How is it that this Rose maintains its high reputation? One is not particularly attracted to it when seen in the exhibition box among its more perfect neighbours. If form were to be the pre-eminent quality, as some individuals would maintain, this variety

would be a long way down the list, for it certainly cannot claim the regular outline of its great rival, *La France*. Yet the fact remains that in the garden it is rapidly superseding the old favourite. The erect habit of the plant, the long flower-stalk, the exquisite bud, and the immense shell-like petals of the expanded flower all conduce to the undoubted popularity of the variety. Another point worthy of consideration to all who require quantities of cut flowers is that it is quite a week earlier than *La France*. By giving it a sheltered spot it might be had ten days in advance of other Hybrid Teas, and this would be of much importance in some establishments. The Americans are sending us a variety, named Mrs. Robert Garrett, which is to supersede *Caroline Testout*. If it does this it will have to be a wonderful Rose.

Rose Gloire Lyonnaise (H. T.).—As a garden Rose this possesses considerable merit. There is something peculiarly attractive about its large expanded blossoms, they being not at all formal. In the bud state it is very lovely, the colour being pale lemon, and although not quite so refined in form as those of a Tea Rose, these buds make very serviceable button-holes. The rigid growth and regular flowering of every shoot are all desirable qualities in a Rose for growing in masses. It, however, is not a variety one should plant in exposed positions, for it is a tender kind. The Brier is the stock for it, as it will not succeed at all on the Manetti, but it strikes freely from cuttings. This Rose is sometimes seen upon walls, and has probably been planted there instead of the more rambling Belle Lyonnaise, with which it is often confounded. The mistake has often turned out a happy one, and I can most certainly recommend it as a semi-climber. The wood is of a reddish colour and but very few spines appear, the foliage rather small, of a rich green colour, combining to set off to the best advantage its beautiful blossoms.—P.

Notes on early-blooming Roses.—The warm sun of the early part of June has had an effect on these in two ways, namely, in bringing many kinds into bloom on warm walls, as also in causing a severe attack of fly. This can be kept in check by the use of some wash. The new insecticide called "Abol" is a step in the right direction. The cold winds had a bad effect on the early-growing kinds in some situations, while in other positions they were untouched. During the last fortnight I have been cutting very nice blooms of Catherine Mermet from a south wall and from plants turned out of pots last June. On the same wall the lovely *L'Idéal* is in bloom. Mme. Faleot claims a place. I doubt if there is another Rose that gives such lovely buds, and this over a long season. Early in June I cut fine blooms from the same position. Some four years ago I had a big plant of *Reine Marie Henriette* in a pot, and I resolved to plant it out at the foot of a south wall. It is wonderful how it has grown, and now (June 16) it is a mass of bloom. Cheshunt Hybrid growing on a north wall is also doing well. I never have had *Rève d'Or* bloom so freely as this year. *Narcisse* must have a word of praise as an early bloomer, and W. Allen Richardson is satisfactory on a sunny wall.—J. Crook.

The four best Penzance Sweet Briers.—That there is too great a sameness in these Sweet Briers must, I think, be admitted by all who have seen and grown the whole collection of sixteen varieties. I think we may safely eliminate a dozen and retain the four following. The first must always be *Lady Penzance*, for with the exception of the Copper Austrian no single Rose is of so lovely a colour. The second variety should be *Anne of Geierstein*. It is a very brilliant kind of the colour of the Hybrid Perpetual *Dr. Andry*. It has two rows of petals, and is also a fine, strong grower, excellent for forming a tall hedge. Either *Amy Robsart* or *Rose Bradwardine* must take the third place, and I am in favour of the former. It is also a fine, strong grower. The flowers consist of two rows of petals and are of the shade of deep rose seen in the Hybrid Perpetual *Mme. Bois*.

As the fourth my selection would be Julia Manning. This variety has also two rows of petals of the most lovely nearly pink colour, so well exemplified in the Hybrid Perpetual Baroness Rothschild. Now what we require to make a good half dozen would be a rich velvety maroon and a pure white, and until these are given us I think the four varieties named will satisfy all tastes. Such Roses as these Hybrid Sweet Briars to be of real use should be effective when seen at some distance; therefore for this reason I have excluded Lord Penzance, for, although distinct and pretty, it has only the appearance of a Dog Rose a few yards away from the plant.—P.

NOTES AND QUESTIONS.—ROSES.

Rose Marie Pare.—This Rose appears to belong to the Chiosas or Monthlies rather than the Bourbons, with which it is classed. It is said to be a seedling from Mrs. Bosanquet, and this surely is more a China Rose than a Bourbon. Whichever tribe it belongs to it is worth growing, and is a most attractive and free-blooming Rose. The colour is clear flesh-pink, deeper in the centre, of medium size, and fairly double. It is a good grower, not, perhaps, so vigorous as its parent.

Rose Camoens on dwarf standards.—This beautiful Monthly Rose (for such it really is in character, although belonging to the Hybrid Teas) makes a pretty show when budded on hedge Briars about 18 inches high; its innumerable and pleasing pink buds and blossoms are so well displayed in this form, and the quality is much superior. If a large mass were desired—and there is no better Rose for the purpose—a few of these dwarf standards to break the flatness would make a charming effect.

A dazzling crimson Rose.—I shall not soon forget the brilliant effect produced by a quantity of the China Rose Cramoisi Supérieur, budded upon Brier cuttings, which I saw last autumn. It was evident the plants had been well cared for, and it proved that if some of our commonest Roses were cultivated with the same care as exhibition varieties, many a grand old sort would be hard to surpass, even by the more modern introductions. Amid the thousands of Roses growing near this variety not one made the same gorgeous display as this fine old Monthly Rose.—P.

Rose Dupuy Jamain.—This grand old Rose holds its own even against modern introductions. The lovely smooth flowers are very fresh, of a clear cherry-rose colour. It is a distinct variety, with as good points as regards growth, free-flowering and freedom from mildew as any Hybrid Perpetual we have. It is one of the earliest to flower of this class and also one of the latest, and for the garden a better and more reliable Rose of its colour could not be named. It fully maintains the character of the red Roses in affording us the delightful fragrance for which they are noted.

Rose Crimson Bedder (H.P.).—This Rose cannot be compared with Marquise de Salisbury and some of the crimson Chinas as a bedding variety, for it is not so continuous in flowering, but, nevertheless, it is very effective in early summer. It would appear to be a seedling from the old Rose Lord Raglan. It is very like it in its flat, crumpled blossoms, and the bright red flowers are similar in colour. The growth, however, differs, for in Crimson Bedder it is moderate, and every shoot is crowned with flower-buds. As these are borne on good stiff stems, the effect is very brilliant.

Rose Princesse de Monaco (Tea).—This lovely climbing Rose was introduced by M. Dubrieul, the raiser of Princesse de Sagan, Marquise de Vivens, Le Soleil, Francis Dubrieul, Perle d'Or, &c. One would take it for a highly-coloured Gloire de Dijon, but its outer petals are richly shaded with chamois and salmon-rose, which gives it a most distinct character. I should not recommend it in preference to Mme. Berard or Mme. Moreau, but where plenty of space is available no one would regret adding this Rose to his col-

lection. It must not be confounded with a dwarf Tea variety, Princesse Alice de Monaco.

Rose Marie Robert (Noisette).—Pink climbing Roses of good quality are none too plentiful, and I feel sure this variety, introduced by M. Scipion Cochet in 1894, will give satisfaction. To begin with, it has an elegant bud, of good length, and prettily recurved at edges of petals like Anna Olivier. The colour is bright rosy pink, and as the flowers expand we have in the centre the rich salmon-rose tint so much admired in Pride of Waltham. Marie Robert is very free and continuous in flowering, and a pretty coat bud can always be obtained from it. It would make an excellent standard, and as a bush, if slightly pruned, it flowers very freely.

The Dawson Rose.—One was pleased to see a favourable reference to this hybrid Rose in the valuable article on "Early-flowering Roses" in THE GARDEN of June 25 (page 533). It is, I understand, a hybrid between R. polyantha and General Jacqueminot, and partakes more of the former than the latter in its characters. Some of the dulness upon which "P." remarks seems to be due to the tendency it has to show white stripes upon its petals. It is not a very rapid grower here, but when it has assumed larger proportions I hope to be better pleased with this Rose than I have been. As it is, its early flowering and its fragrance make it valuable.—S. ARNOTT, *Carslhorn, by Dumfries, N. B.*

New climbing Polyantha Roses.—These excellent little Roses for garden decoration, covering arbours, or for pillars are coming more to the front, and there have been recently some notable additions which will probably be much grown. Thalia, a pure white form which carries large, loosely-built clusters on long, straight stems, has all the appearance of proving an excellent subject for cutting; its semi-double flowers, each a little larger over than a shilling, have the substance of petal that is needed for lasting well in water. Psyche is another novelty of much value, the flowers quite double and of the Crimson Rambler type, but the colour is a light and attractive pink. Diana is said to be a seedling from Crimson Rambler. Its flowers are very double, smaller than those of the parent, and white or very slightly tinted.—J. C. T.

Rose Louis van Houtte (H.P.).—A variety of such a glorious rich crimson colour is worth extra care in order to obtain its grandly-formed, high-centred blossoms. It has a reputation, which I think partly unfounded, of being a very bad grower. It is true it is not over-vigorous, but let anyone bud it upon strong dwarf Briars planted in rich loamy soil, and there is no deep crimson variety to surpass it. I believe it resents transplanting, and I have had the best success with it when the one-year-old plants were allowed to remain where they were budded for two or three years. After this period discard them and a fresh stock can be got ready to take their place. Many Roses of weakly growth would repay anyone to adopt this method of culture: for instance, La Fraicheur, Lady Mary Fitzwilliam, and Gustave Piganeau. All answer to this treatment, and to those who are exhibitors the extra trouble involved will not be wasted. This Rose has the powerful fragrance of La France.—P.

Rose Mme. Isaac Pereire and its sports or seedlings.—This splendid garden Rose, introduced by Margottin in 1880, appears likely to be the founder of a new race. It is evidently a hybrid Bourbon, for it possesses the grand autumnal flowering qualities of the Bourbons; but, like many of the latter tribe, it is also good in early summer. Its colour is light carmine, very pleasing in its freshness: flowers very double and slightly recurved. It is an abundant bloomer, and nearly every bud develops into a perfect flower. It is useful for massing, and altogether a fine garden Rose, but its centre detracts somewhat from its usefulness as a show variety. As a standard no Rose is so suitable, as it makes a fine large head at once showy and vigorous, and it has a sweet fragrance. Mrs. Paul is the reputed

offspring of this variety, and it appears very evident from the vigorous growth. It is, however, distinct from its parent in blossom and colour. In this grand Rose we have a peculiar form, large open flowers like a Camellia, and lovely in the rosy peach shade of colour when young, but liable to lose in freshness when fully expanded. A more recent kind from the Continent, and one that seems likely to come to the front, is Mme. Verrier Cachet. I believe it is a sport from Mme. Isaac Pereire, as it resembles it so much in growth and form of flower. The colour, however, is several shades lighter. There is a perceptible rosy salmon hue in this Rose that should make it popular.—P.

GARDEN FLORA.

PLATE 1179.

THE ZONAL PELARGONIUM.

(WITH A COLOURED PLATE OF MRS. H. CANNELL.*)

WHERE the old ideas of bedding exist in gardens, zonal Pelargoniums (Geraniums) play an important part because of their brilliancy and adaptability to almost any kind of soil. Few plants have undergone so many changes in fashion as have the varied types of this. At one time the rage was for variegated foliage, such as the tricolor, and I can remember how proud I was to possess a plant of that remarkable variety Mrs. Pollock. Huge trained plants of this and improved kinds of the type were considered skilful productions. Now one rarely meets with them as pot plants, and their richly-coloured leaves are not very frequently noted in the flower garden. Then giant specimens of the kinds valuable for their flower-trusses were a leading feature at most summer flower shows. This, too, at the present day seems to have become a lost art, judging from the poorly-grown plants mostly seen. But if the zonal Pelargonium has fallen off in these and other respects, its uses as a pot plant for the supply of bright flowers during the winter months are becoming more widely appreciated.

Although one need not be without blooms throughout the year, their exquisite range of colouring appears with extra brilliancy when all is dull outside. Improved varieties, of which the coloured plate is a good example, bear very fine trusses of well-formed individual pips. Substance in the blooms is also remarkable, and the tints of colour are vivid as well as delicate. Zonal Pelargoniums do not require any particular mixture of soils. In fact, poor soil to my thinking is better than rich combinations. The latter tend to the growth of leaves at the expense of flowers. My compost for these at all seasons is that which has done duty for other plants—Chrysanthemums and the like—and another most important item is to use comparatively small pots. When root-bound they flower most profusely.

Propagation from cuttings may be carried on at any time. I usually dibble in the cuttings among young Tomato plants at this time of the year, and later on up to August root them in the open air, using for this purpose shallow boxes. For winter blooming, spring-struck plants are preferable. These may have two shifts until the final size of pot is of 6 inches diameter. This size is quite large enough, and for later-struck batches I would use a size smaller. Good drainage and firm potting are essential. Of course, when winter bloom is the aim, flower-trusses must be constantly

* Drawn for THE GARDEN by Messrs. Cannell's nursery at Swanley by H. G. Moon. Lithographed and printed by J. L. Giffart.

picked off up to the end of August. The plants may be placed in the open, stood on tiles or boards and regularly watered. Pinch the shoots occasionally to induce a bushy growth. I also thin the leaves so as to obtain stems of a well ripened character. Excellent kinds for winter flowering are Raspail Improved (dark red), Hermine (white), Gustave Emich (light red), Beauté Poitevine (salmon). This last is the same as one now repeatedly exhibited as King of Denmark. Like the others mentioned, this is double, or rather semi-double, and therefore not liable to drop when cut. Those having single blossoms are Albion (white), Charles Mason (scarlet), Enid (rosy red), Countess of Buckingham (pink), Herrick (scarlet), Kitty (soft red), Mlle. Trine (rosy plum), Mrs. Pole Routh (salmon), Olivia (cerise), Phœna (shaded scarlet), T. W. Lawton (salmon). With winter zonals one must guard against high feeding—that is, very little in the way of stimulants is needed. They require a dry atmosphere warmed to about 55° and plenty of light.

Zonal Pelargoniums in summer like shade when in flower under glass, but they want plenty of air. Autumn-rooted plants will give

The Ivy-leaved Pelargonium as a case plant.

the best display, and, to obtain large trusses, young plants are preferred to old ones, although the latter are especially free-flowering. It is better to pinch away blossom-trusses until a good-sized plant is obtained than to let growth and bloom go on at the same time. Both are in that case unsatisfactory. Abundant supplies of moisture at the roots are needed, and in summer the Pelargonium may be stimulated with manures. Liquid made from a bag of soot in the water-tub is what I use, and when in full flower weak doses of guano in the water are given. A few very fine sorts are the following: Cassiope (salmon), Chaucer (cerise-scarlet), Delicata (light pink), Duchess of York (white), E. Bedwell (scarlet), General Wolseley (rosy red), Lord Farrer (scarlet), M. Calvat (crimson), Mrs. Gordon Linzee (salmon), Mrs. H. Camell (salmon), Pink Domino (bright pink), Phyllis (rosy salmon), Royal Purple (deep shade), Souvenir de S. B. Miller (crimson), Trilby (shaded crimson). These are singles. Double blooms are found in Gustave Emich (scarlet), Golden Gate (orange-scarlet), Mme. Charlotte (salmon), Hermine (white), Raspail Improved (dark red).

Apart from its uses as a bedding plant or a subject for conservatory decoration in pots, the

zonal Pelargonium is most effective for filling large vases on terraces or such conspicuous spots near the house. In this instance one must have large plants to begin with, and here is excellent use for the old stumpy specimens which produced their flowers the previous year. They should be cared for throughout the winter and kept into decent shape by timely tying and the removal of straggling shoots. All the better if they have become root-bound. When planted into a free and ample space for the roots in the spring, and well attended to in the matter of water, such plants make a striking display the whole summer. The Ivy-leaved Pelargonium is yet another type well adapted for garden or greenhouse decoration. The trailing growth is best when the plants are placed in boxes or vases, as in the illustration, that it may hang down. Souvenir de Charles Turner and Ryecroft Surprise are the two best sorts I have grown, the one with red flowers, the other pink.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

VINES AND VINERIES.—Those houses from which the crops have all been cut should now be freely ventilated, all the air possible being allowed to remain on both day and night. This will assist in a thorough ripening of the wood and tend to check any later growths. Keep a sharp watch for insects on all such houses now and continue to do so. Insects of no kind whatever can be tolerated any more now than earlier in the season. If it be red spider or thrips, there is a remedy at hand in water. It will not do these Vines any harm to syringe them daily during hot weather, and this alone should keep down both of these insects, but if it do not, then add sulphur to the water for the former and vaporise with XL All for the latter, two doses of which will be quite sufficient. If it be mealy bug, then take stronger measures, syringing with hot water, painting the wood, both the rods and spur growths, with a strong insecticide, and, in fact, using any means to keep this pest down. Then the process of extermination will be lessened later on. Do not now allow any superabundance of growth upon these early Vines. If some growths have been allowed to thicken, making a dense shade, then remove them gradually so that no perceptible check is given to the Vines. What should be done is to take away first the small sappy shoots, which will still continue to excite the roots if not checked. Afterwards other lateral growths can be reduced, so that the first growths from the spurs are only left where stopped the first few times beyond the bunches. My own practice is to first thin out all unripened wood and that which does not give any indication of ripening. After all of this is done, these vineries this season will need little more attention beyond watering. This latter item is all-important, more especially where the borders are entirely inside. Do not on any account allow these to become dry nor the outside ones either should there not be sufficient rainfall to effect the purpose. Vineries with the Grapes now fully ripe should be kept cool, so as to keep the fruit in good condition and free from shrivelling as long as possible. To succeed with this it is a good plan to keep down the night temperature as low as possible during the warm weather, top ventilation at night, at least in a small degree, being the rule except during rainfall, so as to avoid any excess of moisture and its precipitation upon the berries in the morning, as the temperature rises without any ventilation. If fire-heat be used, let it be during the day after the fruit is ripe, and only then when it may perchance be dull and disposed towards a humid atmosphere. Up to the completion of ripening continue to employ fire-heat if need be to keep up the tem-

peratures advised with a little ventilation. Should a large house of Grapes with a plentiful supply of fruit need to be kept over a prolonged period, it will be advisable to lightly shade the roof on the outside with whitening or with flour. The latter is used now in preference to the former, as it does not wash off so readily during the first downpour of rain. Remove it, however, immediately the fruit is all out. Late Grapes and Muscats will, with the comparatively cool period we are now passing through, need the continuance of fire-heat. Whilst this is being written the outside temperature is 48°, and this is not by any means the lowest that has recently been recorded. On the other hand we have had sudden bursts of warmth, but not of long duration, hence it behoves those in charge of the fires to use all needful discretion, and thereby regulate the temperatures accordingly. During hot weather I never mind if the nightly readings are a little below the mark; they afford in some measure a period of rest and recuperation against the trying effects of very hot days. The latest Grapes should have some indications of colouring evident by the end of this month, otherwise there will not be time for them to thoroughly mature, not only in colour, but also in sweetness, before the days perceptibly shorten. Continue to keep all superfluous growth thinned out so that by the time colouring does commence there is not much need of any attention in this respect. Late Grapes are oftentimes disposed to grow away too strongly late in the season. This growth needs to be checked or modified by careful stopping and pinching rather than by the removal of fully developed shoots and leaves in quantity at one time. There may possibly be an occasional berry or two that needs removal, too, before any further advance is made. If so, let this have attention at once, and at the same time lightly and carefully lift the shoulders of those bunches which may have become interwoven with the berries below, then as the final process of swelling goes on the bunches can expand, causing the shoulders to rise without hindrance.

YOUNG VINES, or those planted this year, should be encouraged to make all the growth possible between now and the end of August. To attempt to grow on young Vines without fire-heat is not advisable, especially in a season like the present. In all such vineries the atmosphere should be kept moist and congenial to growth, the house being, as it were, treated similar to a stove in this respect as to closing, but with a little more ventilation during the day. Opinions differ as to the best methods of treating young Vines as regards the extension or the curtailment of the growth. I am disposed to favour extension, and so long as the roof is not unduly crowded do not practise thinning even of laterals. I have adopted the plan, and with advantage, of allowing the main rods only to be tied to the wires, all the lateral growths hanging down below the wires. By this means the new rods which are permanent receive all possible benefit, whereas it is probable some may not do so when the laterals are radiating in all directions upon the trellis at the same level. It tends thereby to the swelling up of the young rods and their earlier maturity too. Should any grower be troubled with a dropping of the young leaves on recently planted Vines, and at the extremities of the shoots in particular, with a pale brownish colour and a tendency towards a glossy appearance, it may be put down as the work of a species of spider, of which we are by no means confined to that known as the red spider. This gave me trouble once when a range was newly planted; therefore I know what a nuisance it is. At first the presence of an insect was not suspected, the leaves dropping in a mysterious manner whilst still small. But upon a close inspection it could be seen what really was the cause, the insect in question being present in sufficient numbers to account for it. Being so minute it may be passed over; in fact, when the leaves so affected were pointed out to some people they did not notice its presence. With the aid, however, of a magnifying glass it may easily be detected. The remedy

I employed was soot only, and it was most effectual. The means adopted for its application was done by putting some soot into small bags, as seed bags, tying them tightly and then sinking them in the water tanks from which the water for syringing was taken. A gallon of soot in a 100-gallon tank would last thus for weeks in an effective condition. What is needed is to extract the better qualities of the soot, not its actual colour, as some most erroneously suppose, and therefore stir the bag about for that purpose. This very minute form of spider is a most insidious pest, and one that should be stopped by the means indicated in an early stage, otherwise the leading shoots are oftentimes crippled for the rest of the season. **HORTUS.**

KITCHEN GARDEN.

CROPPING THE LAND.—This will now be important in this department, as much depends through the next month on the crops next winter and early spring. Of course a great deal depends upon the land and present crop, as often many shifts have to be made to forward the winter crop. At the present date there is a great scarcity of available land for these crops owing to the season being a backward one, and in many gardens one is obliged to use the land for crops that are not always the most suitable. For instance, any of the Brassicas should not follow the same family. At times it is unavoidable, and here I would advise deep digging previous to planting, and if a dressing of artificial manure can be given, so much the better. Cauliflowers may follow early Potatoes, but as the Cauliflower to be good needs ample food it is essential to manure liberally for this crop. The land now planted with Cauliflowers will be in fair condition for roots that do not need rich soil, such as Parsnips and Beets. The land if given a winter dressing of lime or burnt refuse and turned up roughly will be in condition for the root crop. Many who have cleared the land of Broad Beans, Spinach, and Turnips may plant Kales, Broccoli and Brussels Sprouts. For the last I find the Spinach quarters suitable, and in poor soil food may be given, as the Brussels Sprouts take much out of the soil if allowed to attain size and remain till next spring. Brussels Sprouts also do well after early Potatoes, and I would advise deep digging or forking in addition to the lifting of the tubers. I find Onion beds a suitable spot for the spring Cabbage. Give lime freely if at all necessary, as though the work in the garden is now so pressing, it is labour well laid out to free the ground of pests that prey upon the tender plants at a season it is impossible to give remedies. I am now clearing off the Strawberry plants that have borne fruit, burning the plants, dry litter, and weed growth that accumulated during the season and planting Broccoli. Drills are drawn at 2 feet apart. The ground is not dug, it having been heavily manured and double dug for the Strawberry crop. Coleworts do well on the borders that have been cleared of the first early Potatoes, these being planted closely. A nice open piece of land should be reserved for sowing Lettuce next month. Many sow this crop on a sheltered border. The plants often suffer more from being crowded than if given room and grown as hardy as possible. I sow this crop, winter Onions, and late Turnips in a fully exposed position to get the best results. Much the same remarks apply to late Celery; the more open the position the hardier the plants.

GATHERING VEGETABLES.—Few would advise as to gathering, thinking it such a small matter, but on this point much depends, as the plants if not gone over frequently do not produce the best results. Even though the produce may not be needed at the moment, if left it spoils the growth of others, and the plant fails to produce freely. Take French Beans. These are often left on the plants much too long, as the skin hardens and soon loses flavour. The best results are obtained when the pods are gathered young and cooked whole, thus allowing the plants to give better crops. Vegetable Mar-

rows are much best cut in a young state. The plants crop much better if the Marrows are gathered regularly. Cauliflowers at this time of year soon expand, and once they lose that compact build they are of poor quality. Far better cut and store in a cellar in a moist place than leave on the plants if the weather is hot. Roots of any kind growing in a shallow soil need more moisture than those in shade, so that in growing for summer use long-rooting kinds are most suitable. I have found that vegetables gathered during the hottest part of the day from light soils do not keep so well as those gathered early in the day, so that if needed to be sent long distances this is an important point. Mere size in vegetables is no criterion as to quality, and this should be borne in mind where the best are valued.

YOUNG CARROTS.—From October to April the root-store usually provides Carrots, and they are at times large and none too good as regards quality. To keep up a regular supply of small, tender roots it is well to sow this month and not store, but draw as needed. Of course in heavy, clayey, wet soils this is not an easy matter, and in such it would be well to prepare a bed with lighter materials, such as road scrapings, old refuse soil, or anything that lightens. I have found burnt refuse excellent. In cold places it would be well to sow early, but in the south, in light soil, I have obtained excellent results from sowing in August. Wireworm and slugs are very destructive, and these must be cleared previous to sowing, using lime freely, and in badly infested ground I find gas-lime the best insecticide. For use at the season named, such kinds as Model, Early Gem, or Early Nantes are excellent, and in very severe weather it is an easy matter to cover a portion of the quarter with litter, so that the roots may be lifted without damage. I sow in an open position. This sowing gives tender young roots well into April, as if lifted in March and laid in in a cool place they keep sound for some weeks. If sown fairly thick it is well to thin early, but not severely, as these roots do not attain a large size.

TURNIPS FOR WINTER.—The summer has been a good one for these. I never remember so few failures, and it now behoves us to prepare for later supplies. I am aware in the south it is full early for sowing, but not in late districts, and I find it advantageous to make two sowings, one now and another a month later, as by so doing there is no lack of tender roots. Should the autumn be warm the roots at times become large and coarse, and do not keep well; indeed, in my opinion coarse roots are not worth storing. This is my reason for sowing some three weeks later, as roots the size of a cricket ball are large enough for winter use. The land for winter Turnips needs good culture. Manure (well decayed) should not be absent, and I do not think it is well to place the food out of the reach of the roots, as in dry seasons it will support the crop at a time the roots are swelling; it also assists in rapid germination, a necessity with this crop in dry seasons. Turnips are not nearly so tender as supposed, and the roots are not injured by a few degrees of frost. For years I have not lifted till December, but have taken the precaution to mould up late in October, thus preserving them till the latter date. In mild winters in well-drained soil, they may be left in their growing quarters all the winter. It may be asked why risk the crop when they may be stored in October; simply because the roots so soon deteriorate in a warm store, as they grow out badly and lose flavour. For late autumn supplies Criterion and Swan's Egg are splendid types. These do well in most soils. In land infested with insect pests I would advise a dressing of lime and soot; failing this, wood ashes and lime are a splendid fertiliser. So far I have found no Turnip superior to Red Globe for keeping. It is a very solid root, and remains sound for months. The yellow varieties should not be overlooked; indeed, such as Yellow Perfection and Golden Ball are our best winter Turnips, needing less protection and being remarkably sweet and good well into the new year.

For leaving in the soil to provide green tops, a sowing of the latter kinds or Chirk Castle is most useful. These will not need so much room as the earlier roots. These should be from 15 inches to 18 inches apart between the rows to allow of cleaning and working between. With ample room the roots are harder and keep better.

SPINACH.—There is a good demand for this during September and the following month, and to provide a good supply without unduly trenching on the winter sowing it is well to sow now. In very hot summers the seed sown now does not always germinate so readily as one might wish, but this occurs more often in poor soil. I find it well to thoroughly manure for this special autumn crop, as the return from land well done is so great that it is worth a little extra trouble to build up an autumn supply. I am now sowing on land that has been cleared of early Peas, well dressing the ground with decayed cow manure. Avoid thick sowings, or if at all thick thin freely to get strong leafage. A distance of 18 inches between the rows will be none too much, and in land troubled with wireworm give liberal dressings of soot and lime; indeed, I also give a liberal dressing of wood ashes or burnt refuse on the surface previous to sowing the seed, and in the winter when the winter crop is ready the land that has produced a late autumn supply is dug over deeply, the roots dug in, and in the spring it is in good condition for a root crop that does not need fresh manure. Land for the main winter and spring supply should now be prepared, as it is important to clear out wireworm and other pests by exposure previous to sowing early next month.

LETTUCE.—By sowing a good variety of Lettuce at this date there will be no break in the supply. A quick grower will be suitable. I find a medium-sized Lettuce the best for sowing after this date. Large sowings are not needed, far better sow every fortnight for the next two months than make one or two sowings to have a glut of material at one time. Golden Queen is a very beautiful Lettuce for early autumn supplies. I admit it is very tender and will not stand frost, but it will be used before the weather is at all cold, as it is a very quick grower and of the best quality. Tom Thumb is a small grower and very sweet. If a larger is needed the Neapolitan is good. Of Cos varieties, Sutton's Intermediate is the best small autumn Cos I have grown, and invaluable, as it is very hardy. I have had this good well into December. Hick's Hardy Cos and Bath are good, the latter for latest sowings. By sowing now and again as advised, Lettuce may be had good all through the autumn. The seedlings will now lift readily. I find they do well on the Celery trenches. Ground should be prepared for the autumn sowings, and if quantities are needed in the spring it is well to be liberal with the space. Give an open position and do not omit to use lime, soot, or other aids to dress the land, to kill slugs and wireworm previous to sowing the seeds. **S. M.**

AcaIyphas.—Though *AcaIypha Sanderiana* is the only species to claim recognition from a floral point of view, the introduction of such a startling novelty as this has directed a considerable amount of attention to the entire genus, and certainly the beauty of their foliage entitles some of them to a prominent place among this class of plants. The latest addition to ornamental leaved *AcaIyphas* is *A. Godseffiana*, which, like the flowering species above mentioned, was collected in New Guinea by Micholitz. In *A. Godseffiana* the blade of the leaf is 5 inches to 6 inches long and plain green in tint, with a particularly clear cream-coloured margin, varying in width from a quarter to half an inch. In the mature foliage the extreme edge of the leaf, that is, the serrated portion, has just a suspicion of pink. It is of good free growth and its clear, fresh variegation renders it a decided acquisition. Another form in which the marking is limited to the edge of the leaf is *A. marginata*, in which the ground colour is a kind of bronzy olive with a clearly defined margin of rosy carmine. There are several other

forms, and in some of them the leaves show a curious blending of various shades and colours. This is particularly noticeable in *A. tricolor*, also known as *A. Wilkesiana* and *A. musaica*, and when well grown and coloured they are particularly useful for various decorative purposes; the fact that they are readily propagated and quickly attain an effective size being greatly in their favour. During hot summers they are very useful in the mixed beds now so popular, but if the season is wet and cold they are, as with several other subjects, quite ineffective. Most of these fine-foliaged *Acalyphas* were introduced within the dozen years following 1866, and that being just the period when this class of plants was so popular, they were soon in general cultivation. To obtain good coloured specimens they need to be treated much as *Crotons*, that is, fully exposed to a fair amount of sunshine. Red spider is sometimes apt to be troublesome, hence frequent syringing should be given to keep it in check. —T.

KITCHEN GARDEN.

AUTUMN PEAS.

In the northern parts of the country there is less difficulty in getting a good supply of Peas in autumn; but this should not deter growers from getting a fair return in less favoured localities. Locality is not always at fault, as in many gardens the soil, being light, does not suit a late crop of Peas. For many years when there was a much smaller variety of Peas to choose from the kind mostly grown was *Ne Plus Ultra*, an excellent sort still difficult to beat. Even this fails in poor soil on gravel or on chalk. For latest supplies I have more faith in the dwarfier growers, but even then I would advise a strong growing kind. These have more rooting power and are not so readily affected by drought and mildew. It may not be necessary in gardens where autumn Peas thrive to study variety, and where this is the case the grower is fortunate. We have some very excellent kinds to select from, as of late considerable attention has been paid to the raising of dwarfier kinds with a longer pod and of better quality. Some growers fight shy of new varieties, and only recently I was told that *American Wonder* was good enough for anyone. In its day it was an advance in the right direction, but we now have kinds so much superior that no one who studies quality and quantity need grow the one referred to. I am not decrying any kind, however old, but as my object is to get the best results in the autumn much heavier crops can be secured from plants with more vigour. Those who like the very early dwarf kinds will find *Chelsea Gem* all they desire. This is much better than *American Wonder*, and what makes it so useful it is an excellent variety for present sowing in light soils if due attention is paid to the plants in their early stages. A variety which does grandly with me on poor land is *Daisy*; in fact, I consider this the best second early Pea and the best late variety, as its strong-growing haulm, dwarf compact growth, and great quantity of pods make it doubly valuable. This Pea is the result of crossing *Stratagem* with a giant Marrow, and is certainly one of the best we have yet got. *May Queen* is another of the new varieties specially fine for autumn sowing, and, like the one named above, is equally good for early supplies. The plant is dwarf. With me it rarely exceeds 2 feet and it has a full Marrow flavour, and in comparison to its height it bears a large pod. This is as early as the small round varieties, upon which I place little value. Sown in June, it will be ready early in September. I prefer to sow the

first week in July on a cool border and get a later supply. Another good autumn variety is *Early Giant*. This does not produce the quantity of pods with me which *May Queen* does, but in heavier land I saw this variety so good that I must briefly note its value. For many years I grew *Sturdy* for latest supplies, but it is now eclipsed by those noted above. In a light soil *Sturdy* is none too vigorous, and this tells against it in hot, dry seasons. In the north on heavy land *Sturdy* does well. Last year I grew *The Michalmas Pea*, a variety I saw in splendid condition in the Royal Horticultural Society's Gardens at Chiswick a few seasons ago. In growth this is not unlike *Stratagem*, but the pods are blunter and the Peas remarkable for their green colour and excellent table quality. The *Michalmas* grows 2 feet to 3 feet in height and is well worth room in all gardens where late Peas are valued. *Stratagem* sown now is excellent for autumn. The great difficulty I have had with tall varieties at the season named is that they mildew so badly. *Chelsonian* is also an excellent variety. This newer introduction is most prolific and with me is superior to *Ne Plus Ultra*, as it branches more freely. It attains a height of 6 feet. I am not in favour of the tall Peas when a dwarfier section may be planted closer and give a heavier return. I grow the *Chelsonian* for August supplies. A variety half way between the tall and dwarf kinds of recent introduction is a new one named *Continuity*, a very fine type and bearing large pods, strong, dark green haulm, and free of mildew. During a dry autumn it made excellent progress and is rightly named *Continuity*, as it bore very heavy crops until late in the season.

Much depends on culture as to the progress the plants make during the earlier stages of their growth, and in gardens where autumn Peas fail it is well to give special attention in the way of food at the roots. In light soils on gravel or chalk failures will occur unless food is given. I have adopted various means, and one may at times give soil of a heavier nature. I do not mean clay, but a holding soil. I like the dwarf strong growers, averaging 2 feet to 3 feet, because they have less haulm. Though I have to plant closely on account of space at command being limited, by making trenches or deep drills there is a fair return. I give several inches of good rotten manure from the cow yard, and this dug into the bottom of the trench will build up and sustain the plants in dry weather. With trenches or deep drills it is an easy matter to give moisture, and in the hot weather from the end of July to September a mulch over the soil of straw manure with a copious supply of water once a week will keep growth active. I place much importance on mulching in poor soils if the weather is hot and dry, and advise thin sowing to get a strong plant. G. WYTHES.

Pea Earliest Marrow.—Whether this variety can claim the title given it against so many of more recent introduction I cannot determine, as only a representative trial of early sorts would settle the point. However, that does not matter very much to the general reader. The above-named sort may be chosen with advantage as a companion to others of the early section, whether marrow or round. It is hardy, a very free bearer, and grows only about 3 feet high. For an early kind, the pods and Peas are of good size and of excellent flavour. This is particularly noticeable in a raw state. With me this season it is quite as early as the early rounds, which are reduced now to one small sowing, as the early marrows are hardy, equally as productive, and certainly better when cooked. I have

grown *Earliest Marrow* now for several years, and the longer the acquaintance the stronger do the claims of the variety appear. The severe winter weather experienced in March did much damage to the early Peas, but they came through the ordeal well, and their later growth left no suspicion of the disastrous frosts and gales which blackened the leaves and stems, and left them in a condition which made it doubtful whether they would repay the labour and trouble of sowing and staking.—W. S., *Road Ashton*.

Exhibition Onions.—It is not gardeners and amateurs only who try to obtain very fine bulbs of Onions for exhibition. Seedsmen also grow them, as in these days of commercial enterprise it is needful to be up-to-date with exhibits that are not even for competition. The public judge keenly of the merits of a seed-man's produce by the examples he exhibits in public. When I recently saw a remarkably fine lot of Onion plants on a seed farm—and they were very perfect throughout, each plant being about 16 inches apart I asked why so much trouble was taken, and the grower replied, "We must show our stocks in their finest form, and for that purpose we grow all our roots so far as possible under this high-class culture. But for our purposes there is yet another reason, and it is an important one. The finer the bulbs or roots are, the better the seed stocks and the higher average quality will they have when distributed." The public know little of the great care taken in the matter of selection to have everything of the best. There are pieces of Parsnip, Carrot, Beet, and Turnip, besides Onion, and in every case the very finest and handsomest roots that could be found are selected and planted. It is thus possible to have a very clear appreciation of the great value to those in trade of securing the finest exhibition Onions, whether grown by themselves or others. This principle of breeding stocks from the finest and most perfect samples is but identical with the practices of the florist who has been breeding for many years from the best forms and has eventually secured strains that have the highest merit. Ordinary Onion breadths look well, too, this season and seem so far to have escaped harm from the Onion maggot. The season so far has suited roots admirably.—A. D.

The flavour of vegetables.—Flavour, the most essential of all qualities in vegetables, is now out of court in the rush of giant things with fine names that come to us from the seedsmen; the true Brussels Sprout has been "improved" into an acrid ball of vile flavour. Coarse big Beans are given big names, and priced at four times the value of the old Broad Bean, though not one is better in flavour. If anyone will take the trouble to gather some young horse Beans in a field and boil them he will find them better in flavour than any of these Broad Beans. The flavour of the Broccoli sent to the London market in vast quantities is such as to make an epicure for ever give up the use internally of the Brassica tribe. In the Paris markets one can always get French or Kidney Beans of the right size and quality, but our own market has been taken possession of for some years past by a Bean which has a shell as big as that of the razor fish of our shores, and is absolutely without the true Bean flavour. Among the vegetables which perhaps ought to have most care as regards flavour above all others is the garden Turnip, but anyone who takes notice of Turnips as served on our tables will admit how ill-flavoured, acrid, and also most unwholesome they often are. Even the Swede of the field is much more delicate in flavour than most garden Turnips. We never felt this so strongly as lately after some weeks enjoying the good and distinct flavour of the white Turnip of the Paris market, a most delicate vegetable, in shape something like a sausage, and quite distinct from our own varieties. Those who have, unhappily, to rely on the markets for vegetables must take what the market growers give them, and in Covent Garden it is almost impossible to get any with a good flavour, or in a young and tender state, the object of the growers being bulk. The Peas are like

marbles, and are, we think, neither pleasant nor wholesome, so all those who have gardens should insist on quality before everything else.—*Field.*

Pea Veitch's Earliest Marrow.—It is almost superfluous to remark that Peas belonging to this type are always better flavoured than the hard round kinds, but the difficulty hitherto has been to secure a sort which combines earliness with good cropping qualities. This difficulty has, however, been overcome, as the above variety possesses both these qualities, and enables gardeners to place upon the table Peas of far superior quality than was formerly the case when the early rounds had to be entirely relied on for first crops. The above was sown here on January 25 on a warm south border, Extra Selected Early, First and Best, and Harbinger being also sown at the same time. Earliest Marrow was ready for gathering quite as soon as the two first-named sorts, and ten days earlier than Harbinger, while it is equal to all these as regards cropping. Its habit of growth is good, and reaches to a height of 4 feet. The pods, which are curved, are well filled, and the peas when cooked are of excellent quality.—A. W., *Hereford.*

NOTES AND QUESTIONS.—KITCHEN.

Turnip Swan's Egg.—This is a white Turnip, oval, as its name implies. I find these long-shaped roots have a better chance of standing heat and drought than the flat roots, or what are termed the strap-leaved section. The variety in question is not unlike the Turnips grown so largely on the Continent, though the roots are not quite so long. In poor, dry soils it is one of the best, the texture very fine and the flavour delicate. It is not a coarse root. Mine rarely exceeds in size a good Lemon, and it is much liked on that account. Having a small top it occupies but little space, and doing so well in dry seasons makes it a most valuable garden variety. It also keeps well when fully grown if stored in a cool place.—G. WYTHES.

The Swede Turnip for winter.—Very few persons cultivate the Swede in gardens for winter use. The Golden Ball is equally useful as a winter vegetable, but those who care for the Swede would do well to grow a few rows for use at the season named. There are both white and yellow varieties of Swedes. I prefer the yellow-fleshed. One I had last year on trial called Sutton's Yellow was, when cooked, of excellent flavour. The plants are short-topped, roots clean and shapely, and of excellent quality, the flesh being firm and juicy. This should be grown in all gardens, as it is not readily injured by frost. Now is a good time to sow for winter use, giving the plants an open position. A heavy soil will give the best flavoured and most shapely roots.—B. M.

Beet Crimson Ball in summer.—The Turnip-rooted Beets are useful for early supplies for summer salads, and so far I have found none superior to the Crimson Ball. This root is far superior to the Eclipse and Egyptian, as these latter are not always true to name. Few vegetables need more care in selection than Beetroot, and Crimson Ball with me comes very true, and what is so important it is a remarkably early sort. This year, owing to the weather, the roots are three weeks later, but the plants are now making up for lost time and will be ready in a few days. I find this variety excellent for a light soil. The roots, though small, are perfect in shape and of a bright rich red colour, flesh firm and of a fine flavour. Sown in the open early in April the roots will be ready in twelve weeks from time of sowing, and in poor land anyone may with advantage use this variety for autumn supplies by making two or three sowings from April to September.—G. W.

Lettuce, Hicks' Hardy.—I can bear out what "A. W." (p. 510) says respecting the merits

of this good old Lettuce, having proved its hardiness now for several years. I am told that a very similar, if not the same variety, is sent into the English markets from Italy in the winter months as perfect in growth as with us in May and June. By planting in different positions—some under sheltering walls and others in the open, a long supply is maintained. I have not tried Hicks' for frame work in winter, for the simple reason that Endive is preferred at that season, and the Paris and Superb Cos are usually the favourites for the summer, though it is doubtful whether either of these surpasses the winter kind in quality or size. I have not grown them together to prove whether the summer ones develop quicker than the hardy Lettuce under notice. I have seen the ever-popular Bath Cos destroyed in the winter by severe frost, when Hicks' remained and developed large heads. Notwithstanding this, the Bath variety still retains a high place, and will, I have no doubt, continue to do so, for growers are slow to give up old and well-proved kinds at the expense of newer ones of which they have no experience. Hicks' grows to as large a size as the Bath Cos, and has the advantage of being self-folding, when the latter needs to be tied up to become perfectly blanched.—W. S., *Wills.*

Coleworts.—Being rather a large grower of Coleworts, I am pleased to see that "S. M.," in

Pear Easter Beurre.

his calendar notes for June 18, advises the growing of this excellent quick-hearting Cabbage for autumn and winter use. I usually make the first sowing of seed the first week in June, and another at the latter end of the month. From these two sowings I generally have about 4000 plants set out at intervals. The first batch comes in in the autumn, after which there is an uninterrupted supply until March, when Ellan's Spring Cabbage is usually ready for use. These Coleworts succeed Potatoes, and are planted without the ground having any further preparation beyond that which it receives when lifting the crop. If the weather is dry, the roots of the plants are dipped in a puddle of clay and water, with a little soot added before planting, and then watered home afterwards. "S. M.'s" hint as to planting in drills is a good one, as it not only prevents a waste of water in a dry time, but it also saves moulding up afterwards, as all that is required is to fill in the drills. I do not grow the Hardy Green variety, but rely entirely on the Rosette or London Colewort, which always stands the winter well with me. This is a valuable Cabbage for amateurs and others having but small gardens to plant for autumn and winter supply, as the ground can be cleared quickly, and in time for it to be prepared again for spring cropping.—A. W.

ORCHARD AND FRUIT GARDEN.

PEAR EASTER BEURRE.

OPINIONS vary greatly as to the value of this very old Pear for general culture in England, and I have seen it stated that it is valueless in the northern districts. My experience is that it is indispensable where late Pears are a necessity, but that it requires high culture on a wall with a south or south-west aspect to develop good flavour and a juicy texture. Certainly when at its best, as grown in England, it is first-rate in quality, though we cannot compete for size with the huge specimens imported from California. More than twenty years ago it used to be well grown at Wynyard Park, Durham, a district which is not specially favoured in the matter of climate, and I have also met with excellent examples in Suffolk, Gloucestershire, Cornwall, Hampshire, and Bedfordshire, but have noticed in each case that all the fruits of good quality were produced by comparatively young trees, and I have not found the ordinary methods of resuscitating very old trees, by reducing fruit spurs, root-pruning, and relaying the roots in fresh soil, of much avail in altering the character of fruits produced by such trees of Easter Beurre, though with other varieties the effect has been strongly marked. Judging from this and from the character of fruits given by younger trees, the best way of dealing with this Pear would be to plant relays of cord-on-grown trees on the Quince stock at intervals of a few years, and to grub out all that show signs of developing small, spotted fruits of a woody texture.

Much may be done in the matter of keeping the trees thrifty by thinning down the fruits rigorously whenever there is a heavy set, which will be probably every year favourable to Pears, as the tree is a great bearer, shortening back the fruit-spurs at pruning time and feeding well throughout dry seasons, doing everything in fact to encourage strong, healthy growth with plump and vigorous fruit-buds, and not too many of them. Good trees may be had on the free stock and also double-worked, but the tendency of the day is to plant single cordons of late Pears thickly on walls in favourable positions, and these trees will give by far the most satisfactory results where there are no difficulties in the way of obtaining them when wanted.

A good Easter Beurre should be above medium size, roundish oblong in form, green ground colour (changing to yellowish green as the fruit ripens), covered with dots of russet, and with a flush of reddish brown covering most of the sunny side of the fruits, and a small eye. The flavour is distinct and good, the flesh white, melting, and refreshing. The fruits often ripen in December and January, but may be kept in good condition till March, as they do not readily decay.

J. C. TALLACK.

Strawberry Leader.—Having grown and fruited this Strawberry along with Royal Sovereign on a south border with a view to test its earliness, I am now in a position to state that there is quite a difference of seven days between the two, as Royal Sovereign was ripe on June 17, while Leader was not ready until the 24th. Leader is a more compact grower than Royal

Sovereign; the leaf-stalks are much shorter, and it is also an excellent cropper. The individual fruits are large and fairly well coloured, but in my opinion the flavour is neither so good nor is the flesh so firm as in Royal Sovereign. According to its behaviour with me it will be a good sort to come in between the last-named variety and Sir J. Paxton, particularly in a backward season like the present one, as it would prevent any possible break occurring in the supply. Royal Sovereign, therefore, still retains its position as a first early, and will continue to do so until superseded by something better, which, I venture to think, will be some time.—A. W.

MORELLO CHERRIES.

BOTH bush and wall trees here have set wonderful crops of fruit, which is now passing through the stoning period. Judging by appearances, but a small percentage is likely to drop after stoning is completed, and should this prove to be correct the trees must have generous treatment or the fruits will otherwise be but small. Morello Cherries are so much sought after that they are never too plentiful, and I know that in my own case, although large quantities are annually grown for a private garden, the supply never exceeds the demand. It is therefore one of the most profitable outdoor fruit crops that can be grown in a private garden, and one deserving of special treatment as regards feeding and keeping the trees in a clean, healthy condition. When a heavy set is secured, one hardly likes to thin the fruits down as with the sweet varieties, neither is it necessary that it should be done if the precaution is only taken to render the trees every assistance while perfecting their fruit. If the roots are judiciously fed no ill effects follow, and the trees continue to bear year after year so long as this course of treatment is pursued. The roots of the Morello naturally feed near the surface, and if a winter mulch of half-rotten manure or horse droppings is given annually it proves of the utmost value in keeping the trees in robust health. This mulch in course of time becomes permeated with a regular network of roots, but if liquid or chemical manures are given in addition after the stoning period is safely passed magnificent fruits are the result. Even ample supplies of water alone greatly enhance the size should the weather be dry enough to warrant their free and frequent use, but the additional aid of a stimulant improves and enriches the flavour. A good manure is equal quantities of muriate of potash, bonemeal and superphosphate of lime. Strew it on the surface of the border at the rate of 2 ozs. per square yard and wash it in at once. If the border should be dry, take the precaution to moisten the soil before applying the manure, otherwise great waste will ensue.

At this time of the year black aphid generally proves troublesome, much depending on the amount of attention given the trees in the way of washing or syringing them. If hosed or forcibly washed by means of a garden engine every few days these pests have small opportunity to obtain a footing, but if once allowed to settle on the points of the young shoots the aid of insecticides and the exercise of a good deal of patience become necessary before they can be subdued. Killmright, mixed and applied at full strength or 2 ozs. to the gallon, is a most excellent remedy. Soapsuds is another, and this may be applied at a temperature of 95°. In bad cases use Tobacco water with a little soft soap added, and wash frequently afterwards or until the fruit begins to colour. Another matter calling for attention, and which materially assists in the production of fine fruit,

is the stopping or pinching of the points of the young shoots on bush trees so soon as the stones or seeds are quite hard. The same remarks apply to the removal of superfluous growths on wall trees. These should be well thinned out and no more retained than will be necessary for furnishing the trees with bearing wood for another season. These young shoots should be neatly fastened back to the wall or tied to the trellis. They are then more easily kept clean than when allowed to stand straight out from the wall, to say nothing of their looking much neater. The next thing is to preserve the produce as soon as it commences to show colour, for blackbirds and thrushes—which, by the way, are more numerous than ever this season—soon make short work of them if they are left unprotected. A net, with a forked stick here and there to keep it away from the wall, with the lower edges pegged down securely to the border, is the most effectual means of preserving the fruit from these marauders. It is always a wise proceeding to well wash the trees prior to netting whether aphid is present or not, as remedial measures cannot well be adopted after the Cherries begin to colour generally. A. W.

MOVABLE COPINGS FOR WALLS.

MONS. F. JAMIN, of Bourg-la-Reine, in reply to a query of ours as to the mode of protecting Peach trees when in flower, sends us the following sketch and note:—

Most of my walls are furnished with fixed or permanent copings, but I have some walls with movable copings, an illustration of which I herewith send you.

The shanks should be fastened in the wall at exactly the same angle, so as to present a uniform inclination of about 15°, and should be set 3 feet apart, but the covering-boards are fastened to them only at points 6 feet apart. I would recommend you to make a trial in constructing one of these copings before you start to make them more extensively. A clever workman will see at once what is required to be done. I forgot to mention that this movable coping should project about 15 inches from the wall. At Montrenil the coping is most usually made with rye straw, which is economical, but not durable. In England rye straw is hardly obtainable, but wheat straw might be very well used in its stead.

Frogmore Orange Melon.—Under its first trial this variety has given great satisfaction. The plant has a very good constitution and sets its fruit freely. The fruit is handsome in form and very good in quality. This is almost all that is needed in a Melon, but it is a condition that does not always follow a new or an old variety. In varying soils and under the treatment of growers

who have methods differing one from the other, Melons of no one kind can be said to be universally reliable, and the same probably may be said of the one under notice. In my case it has not grown to a large size, nor is this needed, smaller fruits being in greater demand. The variety, however, has given such a favourable account of itself that it takes a place in the list selected for future sowing. This Melon develops into a totally different fruit from what it promises in its early stages. Then it is extremely hirsute, and would appear elongated rather than round, which it is when fully grown. It is prettily though not densely netted, of a pale golden colour. For its size it has a good depth of flesh, which is, when ripe, very melting. It belongs to the white-fleshed section.—W. S., *Wills*.

SUMMER PRUNING OF FRUIT TREES.

THE time has come when, even under the pressure of work of all kinds, wall and other trees demand some attention in the removal of the lateral growth, now so conspicuous everywhere. There is sometimes anxiety on the part of some gardeners to do such work early in the summer, so as to render the trees neater to the eye, but there is not always a gain in commencing so soon, for it invariably leads to having a second or even a third attempt before the work of the season is complete. This is not the only evil for too early a start; if the pruning is done with any attempt to a final one, the basal buds may be forced into a lateral growth this season, when, left alone a short time longer, they would probably be developing fruit-buds for future bearing. Thus two evils arise, giving additional labour this year and jeopardising next year's crop, simply from trying to make the garden and trees trim and neat too early in the summer. This year the frequent rains have given rise to a continued growth, and in some instances this is stimulated by the lightness of crops borne. Gooseberries furnish a notable example in these gardens. I have never had such a luxuriant growth as this year, or so light a crop. These have just been lightly pruned so as to render the gathering somewhat more easy, for with such a wealth of lateral growth, fruit-picking was by no means easy. Hoeing, too, can be much more easily done when there is more room, weeds this season having an agreeable time while the storms were so frequent. Currants, where the fruit is required for immediate use, can be shortened somewhat to advantage, but in too many instances there is but little time to spare for these until after the crop is cleared. For late use the extra foliage would do good by shading the fruit from the hot sun. Plums on walls always form a lot of breast-wood, and it may be said no trees more resent early pruning than the Plum; shortened early, a quick succession of laterals pushes forth immediately. Cordon or restricted Plums are greater offenders in this matter than others having more room, and it matters not so much whether the crop is light or heavy in their case. Pears do not maintain such a continuous growth as Plums. What shortening is done now will be permanent, and Apples, though they differ from Pears in the lateness of the summer growth, will not give much trouble after this date. Peaches and Nectarines need to be attended to often in the needful nailing and thinning. Where there is any suspicion of crowding, very strong shoots are better pulled out altogether, or, if there is room for nailing or tying in lateral growth, they are better stopped, and the secondary shoots laid in for next year's fruiting. It is a good rule, but one not generally carried out, to allow at least 6 inches between every bearing branch of Peach or

Nectarine. This allows the sun to reach every leaf, and growth made under such conditions cannot be other than well ripened at the end of the summer. Apricots need the same early and constant attention as Peaches; it is unwise to allow a quantity of growth to develop to be cut away at one pruning. The finger and thumb can more safely do the pruning of the Apricot, at any rate with young trees or those having a tendency to develop an unusual quantity of breast-wood. Old trees which generally carry large crops make but little work in the matter of pruning.

The free growth of Cherries, both dessert and Morello, is often useful in keeping off the nets to a distance, making it difficult for birds to reach the fruit when ripe. It is not fair to the trees to be left so long uncareed for, but unless the nets are set out by some means, birds, especially thrushes, will reach the fruit. Some of the superabundant shoots can be cut out before the nets are put on. The early Cherry crop would be cleared in time to do the necessary pruning and nailing of the summer growths. Raspberries should not be overlooked even at this busy period. If the suckers are reduced sufficiently for giving the required number for bearing next year, these must be stronger and better than if left alone. Crowded Raspberries are liable to be severely crippled in the winter should this be a severe one, from the fact that the growth does not become well matured. W. S.

Wills.

NOTES AND QUESTIONS.—FRUIT.

Apple Boston Russet.—If S. Dean, Maidenhead, will let the fruit hang on the tree as long as possible, he need not be afraid of a few degrees of frost. After gathering the fruit, place it in a rather close, cold, dark room, and he will have no difficulty in having a fine sample of fruit in May.—RICHARD NISHIT, Longford Cottage, Market Drayton.

Fruit at Richmond.—That very fine new Peach Thos. Rivers was shown in good form at Richmond on the 29th ult. It is, as produced on pot trees, remarkably fine, very round, brightly coloured and handsome. Without doubt on a trellis-trained tree close to the glass the fruits will be richly coloured. It is when so grown that a fair test of its table quality can be best obtained. Early Rivers Nectarine was also very fine, so, too, were Early Rivers (black) and Belle d'Orleans (white) Cherries, the latter being almost transparent. Very interesting were handsome new forced fruits of Red Astrachan Apple, and Buckingham and Wagener Apples of last year in very fair condition. A little-known late Apple, not unlike Tower of Glamis in form, Reinette Rambon de Melcher, was very firm. There were also good Czar Plums. Fruit in the collections was but moderately good, the best being capital Madresfield Court Grapes from Clendon Park, Surrey.—A. D.

Annual Strawberries.—The term annual now so commonly applied to young plantations of Strawberries, whilst well understood by gardeners, is rather misleading to the unlearned, as I have found. Practically the Strawberry, though a perennial, is, when treated as annual so-called, really a biennial. The term annual is used because the plants are planted and fruited within the twelve months, and, as a rule, are then destroyed. Still, there is nothing new in this practice but the term annual. Strawberry plants, if from early runners, have been planted and fruited within the year ever since they have been garden fruits. The novelty, what little there is in that, is found in planting relatively thick, getting a good crop of fruit the next year, then destroying the plants. Early in the century it was common practice to plant in beds and allow them to remain almost thickets for several years.—A. D.

TREES AND SHRUBS.

SPIRÆA FLAGELLIFORMIS.

WHILE the different Spiræas include among their number some of our very finest flowering shrubs, they are so numerous that in most cases a rigid selection is necessary. If restricted, however, to a dozen distinct forms, *S. flagelliformis* must have a place, as it is a very beautiful free-blooming kind and one that does not flower till many others are past. The Spiræa is in style of growth very different from most members of the genus, the principal shoots being more or less upright, while the growth is quite spreading, and the long slender shoots, which droop gracefully on all sides, are thickly studded for some distance with little flat clusters of white blossoms. When at their best, the longest shoots form veritable floral wreaths. Though so long known in gardens and nurseries as *S. flagelliformis*, it is now considered to be synony-

liberally treated is so great, that the two might be taken as belonging to distinct species. It should if possible be planted where there is ample space for the development of its somewhat spreading branches, as a great deal of the beauty of the specimen depends upon the long arching shoots being allowed to grow unfettered, for they then dispose themselves in a very graceful manner.

Philadelphus microphyllus.—The intercrossing of the few leading types of *Philadelphus*, and the great number of intermediate forms that come between them, make the genus a most difficult one to study—even among hardy trees and shrubs. But amidst all the confusion that exists, *P. microphyllus* stands out distinct. It is the smallest of the *Philadelphuses* in stature, in leaf, and flower. These characters, however, are not defects, for whilst they adapt the plant to situations to which the larger and commoner types would be unsuited, it has at the same time all that profusion and fragrance of blossom which have made

Spiræa flagelliformis.

mous with *S. canescens*, or at all events but a variety thereof. *S. canescens*, which is a native of the Himalayas, is a somewhat variable species, and therefore possesses a considerable list of synonyms; indeed, in the Kew list it has more assigned to it than any other Spiræa. Names under which it may be met with are *S. cuneifolia*, *S. flagellaris*, *S. hypericifolia*, *S. crenata*, *S. nutans*, *S. ruscifolia*, *S. nepalensis*, *S. rhamnifolia* and others. It is as a rule at its best from the end of June onwards, and in good soil where it does not suffer from drought this Spiræa will continue to bloom for a considerable time.

Like all the others, it needs to be planted in good deep soil that is not parched up at any time, for though it will hold its own and flower freely under adverse conditions, yet the contrast between a plant so situated and one more

the *Philadelphuses* such general favourites. The leaves are ovate, each about half an inch long on the flowering shoots (twice as large on the young growing shoots), of a rather greyish shade of green and covered, especially beneath, with short hairs. The pure white flowers are each about 1 inch across. The plant is a small rounded bush, 2 feet to 3 feet high, consisting of a dense thicket of slender wiry stems and abundant foliage. It is suitable for the rock garden, and being a native of Colorado, Texas, Utah, &c., is interesting as a shrub that is perfectly hardy in this country, coming from a region where very few are to be found of which so much can be said.—W. J. B.

Cistus laurifolius.—Whilst most of the *Cistuses* that were figured by Robert Sweet seventy years ago in his valuable book "Cistinea" are scarcely cultivated or even known in Britain nowadays, a few species can still be counted among useful hardy shrubs. Among the "survival" of

the fittest" the best is the present species. I have not had experience with it in districts more unfavourable to tender plants than the London one, but here it is perfectly hardy. Not even the early part of 1895, when the thermometer was frequently near zero, affected it in the least. During the latter part of June, and now in July, it is perhaps the showiest of hardy shrubs. Its flowers are of the purest white and each about 3 inches across. Every morning a fresh crop of them robes the plant anew. There is a rare and beautiful variety called *maculatus*, in which the base of each petal is marked with a large blotch of crimson. The species is evergreen and has large dark green leaves, covered with a viscid substance above and with a pale brownish felt beneath. It is a native of South-west Europe: still it ripens seed in this country in plenty. For rather dry banks that are not easy to furnish satisfactorily with tall evergreens it proves specially valuable. It will grow from 6 feet to 8 feet high, and although liable to become bare at the base through age, it can so easily be replenished or renewed by means of seed that this constitutes but a slight disadvantage.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 12.

THE remarkable display of plants, flowers, and fruit on Tuesday last must be pronounced an unqualified success. The show was well nigh replete in every particular, and upon this occasion enhanced by the lovely display of Roses. We cannot refrain from mentioning the remarkable blooms staged by Mr. Orpen in every class. Finer or better coloured flowers have in all probability never been staged at this or any other meeting. Hardy flowers, though less numerous than at some previous meetings, were abundant, and among them a notable collection of Lilies from Messrs. Wallace, of Colchester. Sweet Peas abounded, some four groups alone of these being set up, while eating Peas, as befitted the lecture arranged for the afternoon, came also in considerable quantity. Carnations of the Malmaison section were again to the front, Mr. Martin Smith having many good things. Novelties were rather numerous, and the floral committee, before whom a large number of exhibits came, sat to a late hour. Orchids were in the minority, while Ferns in their infinite shades of green on a hot July day were also restful to the eye. In the afternoon visitors were numerous.

Fruit was very prominent, a fine collection, of which Her Majesty was the exhibitor, being staged by Mr. Owen Thomas. Cherries, Peaches, Melons, Strawberries, Tomatoes, &c., in many leading kinds being well represented. The Messrs. Veitch likewise contributed abundantly of Cherries, in pots and also gathered, as well as Strawberries.

Orchid Committee.

A silver Banksian medal and cultural commendation were awarded to Mr. H. Hicks, Brantwood, Chelmsford, Essex, for a remarkable specimen of *Dendrobium Dearei*, with growths each upwards of 3 feet in length. It had eleven flowering growths with thirteen expanded spikes of bloom, several others being in bud. Several of the spikes had ten flowers each. The plant had been grown in an ordinary stove for the last four years. It was undoubtedly the finest specimen we have seen. Sir Trevor Lawrence was awarded a Botanical certificate for *Oncidium albo-verrucosum*, a pretty form, in growth resembling *Odontoglossum crispum*. The flowers are produced on dense spikes, each about 2 feet in length, the sepals rich yellow, the petals yellow, with dark brown blotches at the base, the broad three-lobed lip rich yellow, with an indistinct bar of brown at the base in front of the raised white disc.

Messrs. H. Low and Co. sent a small collection of choice Orchids. The most prominent was *Cattleya Gaskelliana alba*, a lovely variety with

pure white sepals and petals of fine form and substance. The large beautifully fringed lip is white with rich orange-yellow through the throat. Another light form was also included. This had blush sepals and petals with a slight tint of rose in the centre of the lip. The plant carried three spikes of flowers with three flowers each. A good form of *C. Warszewiczii*, *Cypripedium T. W. Bond* (*Curtisi* × *hirsutissimum*), having the intermediate characteristics of both parents; and *C. Alice* (*Spicerianum* × *Stonei*), in which the dorsal sepal is white suffused with rose, slightly spotted with small purple spots, the petals greenish-yellow, spotted and suffused with deep brown, were sent. *Bulbophyllum elaptonense* has the dorsal sepal yellow, netted with transparent white, the lower sepals yellow at the base, shading to white at the apex, the reflexed petals yellow at the base, with a lighter apex, the lip white, shading to purple at the base. A grand form of *Odontoglossum citrosum* and a very large form of *Dendrobium Dalhousianum* were also included. Mr. W. Bull, King's Road, Chelsea, sent *Oncidium maerantherum chelseanense*, a pretty form, with darker sepals than usually seen in the type. Mr. J. W. Temple, Leyswood, Tunbridge Wells, sent a large group consisting wholly of specimen plants of *Cattleya Warszewiczii* (*gigas*) remarkably well grown, the flowers being fine in substance and in various shades of colour, many of the scapes having as many as six blooms. The group was very tastefully arranged with *Asparagus* and Ferns. A silver Flora medal was awarded. Sir F. Wigan sent *Cattleya Warszewiczii Rothschildiana*, a pretty dark form, without the usual yellow disc in the throat. Baron Schroder sent a form of *Odontoglossum crispum* of the *O. crispum Lehmanni* type. Sir T. Lawrence showed *Vanda Miss Agnes Joaquim*, having a raceme of fifteen flowers and buds. In this the sepals are pale rose, the lower ones nearly white, the flat petals deep rose, the front of the lip deep rose, shading to purple, suffused with brown and shading to white at the base, the whole being spotted with small rich brown and purple spots, the side lobes rich purple, shading to amber at the base. The plant received a first-class certificate last year. A cultural commendation was awarded on this occasion.

Floral Committee.

The following plants obtained first-class certificates:—

ASPLENIUM ORNATUM.—This is a graceful and distinct as well as elegant plant, with dark green, shining, well-divided fronds, the elongated linear segments frequently twice and thrice divided, and, so to speak, lacerated to a considerable depth. It is an acquisition. From Mr. H. B. May, Dyson's Lane Nurseries, Edmonton.

PICEA FENSIS GLAUCA PENDULA.—A very striking and beautiful drooping form of the Colorado Spruce, standing nearly 9 feet high, the pendent branches having an exceedingly heavy glaucous blue tone. From Messrs. Koster and Co., Hollandia Nurseries, Boskoop, Holland.

Awards of merit were given to the following:—

CARNATION NELL GWYNNE.—A pure white of the Malmaison type, the flowers not so large as usually seen, probably on account of the more natural growth. From Mr. James Douglas, Bookham, Surrey.

CARNATION MRS. MARTIN SMITH.—A large and handsome flower of the Malmaison type, in which the colour is a good clear rose-pink, a shade or so darker than in the well-known *Duchess of Fife*. From Mr. Martin Smith, Hayes, Kent.

CARNATION CALYPSO.—Also a Malmaison kind of the largest size, the colour a very distinct blush, shaded pink. From Mr. Martin Smith.

ROSE PERLE DES ROUGES.—An exceedingly dwarf and richly-coloured member of the *Polyantha* section, the colour a distinct glowing crimson-velvet. From Messrs. Wm. Paul and Son, Waltham Cross.

CARNATION SUNDRIDGE.—A very handsome self coloured scarlet kind of a rich glowing shade and very fine form. It is a border kind of rather tall habit. From Mr. E. Tapper, Sundridge Park.

ROSE EDITH TURNER.—An addition to the H.P. group, the flowers full and possessing somewhat of the recurving petals of *La France*, while the colour is of a soft and delicate blush-pink shade. From Mr. C. Turner, Slough.

SWEET PEA AURORA.—A very good and well formed flower, the standards nearly ovate and of large size, the varying shades of scarlet and orange-scarlet being waved over a light ground, the latter well-nigh hidden where the deeper shade prevails. From Mr. F. G. Foster, Havant, Hants.

SWEET PEA GOLDEN GATE.—The name here given is a misnomer, the prevailing shade of colour being shades of violet, mauve and blue. The form is good and the flowers freely borne. From Mr. F. G. Foster, Brockhampton Nurseries, Havant.

POLYSTICHUM ANGLICUM × **ACULEATUM.**—This, as may be imagined, has produced a very striking and remarkable form, in which the latter parent is abundantly clear. There is also much of the *P. aculeatum* type in the rough hoary character of the rachis and fronds generally, the latter being from 2½ feet to 3 feet in length. In the hardy fernery this should prove most effective. From Mr. W. Marshall, Auchinraith, Bexley.

Messrs. R. Wallace and Co., Colchester, brought a fine display of Liliiums, perhaps the most complete collection of these flowers ever seen at one exhibition, and which included some twenty-four varieties. Among the most prominent were *Poezli dalmaticum*, *Washingtonianum*, *pardalinum*, *californicum*, the lovely *Henry*, *Parry*, with rich golden flowers, *Browni*, *Hansonii*, *canadense*, *Szovitzianum*, *Martagon album*, *speciosum album novum*, with pure white flowers, and the lovely *Humboldtii magnificum*, with its broad segments, heavily spotted and completely recurved. Besides these there were many beautiful forms of *Thunbergianum* and *umbellatum*, together with *Calochorti* in variety and other beautiful things (bronze Banksian medal). Malmaison Carnations were again well exhibited by Mr. Martin Smith, Hayes, a large half circular group being simply a mass of the lovely flowers. Two varieties received awards on this occasion, one of them, *Mrs. Martin Smith*, being in strong force in this group; indeed, the latter was largely composed of this kind, with *Calypso*, and such as *Lady Grimston*, *The Geisha*, *Lord Welby*, *Mrs. Trelawny*, &c. The yellow border kind *Cecilia* was also in fine form (silver-gilt Banksian). Another group of Malmaisons came from Mr. Daniel Cooper, Warren Tower, Newmarket (gardener, Mr. Thos. Young). This lot was mostly of the blush and pink kinds, the plants being finely grown and well flowered throughout. A fine batch of Carnations, mostly of the Malmaison type, came also from Mr. James Douglas, Edenside, Bookham, the most prominent being *Nell Gwynne* (pure white), *Prime Minister*, *Lady Grimston*, together with such as *Mrs. James Douglas*, *Richmond* (fine white), *Ellin* (white, large flaked petal), *Trumpeter* (scarlet, very good), and others. Mr. George Reynolds, gardener to Messrs. de Rothschild, had a very striking flower called *Mrs. L. de Rothschild*, a carmine rose shade, very telling and quite distinct, the plants bold and handsome and of great vigour. The Duke of Marlborough (gardener, Mr. Whillans) showed among others a fine scarlet called *Oxford Yeoman*; the plant of this is fully 6 feet high, the colour very fine. Sweet Peas were shown in great numbers as well as variety by at least four of the leading growers, and though arranged in various parts of the hall made a fine display. In the Messrs. Cannell's lot some seventy two varieties were staged, the colours endless, and the varieties in many instances of considerable promise (silver Banksian medal). Mr. Eckford, Wem, Salop, likewise had a very large display, this including many novelties, such as *Lady Skelmersdale*, white and purple; *Bouverie*, salmon-bronze with pink; *Lady Mary Currie*, brilliant carmine; *Mrs. Joseph Chamberlain*, white and scarlet; and *Fascinator*, purple-blue and bronze (silver Banksian medal). Mr. F. G. Foster, Brockhampton

Nursery, Havant, also had a fine lot, mostly new kinds, among which Aurora, Golden Gate, Sensation, Oriental, Modesty, delicate pink, Dolly Varden, Stella Morse, deep primrose-yellow, Colonel, soft lilac, Lady Grisel Hamilton, lavender, very pretty, were distinctly noticeable (silver Flora medal). A small group of the dwarf sorts of Cupid in pots came from Mr. N. N. Sherwood, Dunedin, Streatham Hill, the plants nicely flowered. Messrs. Veitch and Sons, Chelsea, filled a long table with annuals and biennials in very great variety, such things as Rhodanthe in variety, *Bartonia aurea*, the pretty *Platystemon californicum*, with its yellow blossoms; *Godetia Whitneyi*, a very showy kind with rosy-red flowers of large size; *Linarias*, many beautiful Poppies, *Marguerite Carnations*, lovely Canterbury Bells in many colours, *Venidium calendulaceum*, Lupins, *Oxyura Douglasi* with *Marguerite*-like yellow blossoms, *Limnanthes Douglasi*, *Placelia campanularia*, the most charming bit of blue imaginable, *Coruflowers*, grasses, and other things, the same firm contributing groups of *Richardia Relmanti*, soft rose spathes, *Cytisus nigricans*, *Rubus canadensis rosea*, *Spirea bullata* (*crispifolia*), and others, the whole forming a very effective and pretty group. Messrs. J. Carter and Co., High Holborn, had a fine display of choice Delphiniums, bold towering spikes being arranged in a very liberal manner along the back, while a large assortment of the choicest Sweet Peas arranged in Oriental bowls was greatly admired. These bowls were about 8 inches or 9 inches across and about 4 inches deep, the sprays of blossom being tightly arranged throughout, thus making a very pleasing display of these useful flowers, for which a silver Banksian medal was awarded.

The Ferns from Mr. H. B. May, Edmonton, on this occasion consisted of a collection of sixty-five species and varieties of *Aspleniums*, a few of the best being *ornatum*, *cicutatum*, *elegantissimum*, *Colensoi*, *divaricatum*, *laxum pumilum*, *Herbsti*, a bold, shining-leaved kind, &c., and fine flowering examples of *Exacum macranthum*, with lovely heads of the richest royal purple on plants 2½ feet high; *Swainsonia galegifolia alba*, very free and pure; and *Abutilon Golden Fleece* (silver-gilt Banksian medal). Another collection of Ferns from Messrs. E. G. Hill and Son, Edmonton, included many good kinds, such as *Asplenium Hilli*, *A. ornatum*, *A. Nidus-avis*, *Lastrea lapida*, *Davallia fijiensis elegans* and *D. f. robusta*, many beautiful warm-tinted *Adiantums*, *Nephrolepis rufescens tripinnatifida*, several *Gymnogrammas*, and others (silver Banksian medal).

A choice assortment of *Iris Kempferi* from Messrs. Barr and Son, Covent Garden, included many good things, the majority being named sorts, though the somewhat short stems employed do not display these things to the best advantage. The collection included some thirty or forty kinds. Several handsome spikes of *Eremurus Bungei* with yellow flowers were also shown (silver Banksian medal).

Fruit Committee.

There was plenty of work for this committee. The exhibits were numerous, the fruit from the Royal Gardens being first-rate. Messrs. Veitch and Sons also staging excellent fruit trees in pots and Strawberries. Grapes, Melons and vegetables were also shown in quantity.

First-class certificates were given to—

STRAWBERRY VEITCH'S PROLIFIC, the result of crossing Empress of India with British Queen. This is a pale red wedge-shaped fruit. It is a free grower, the flavour being very fine, partaking largely of that of the British Queen. From Messrs. Veitch and Sons, Ltd., Chelsea.

CUCUMBER SENSATION.—This is a beautiful fruit, of perfect shape, with scarcely any neck. It is a smooth fruit and one of the most shapely Cucumbers the committee have ever had before them. The quality is very fine also. This was obtained by crossing Matchless with Telegraph. From Mr. Mortimer, Farnham, Surrey.

From the Royal Gardens, Windsor, Mr. O. Thomas sent a large collection of fruit, including

Cherries, Peaches, Strawberries and Tomatoes. The Cherries were very fine, especially Royal Duke, May Duke, Archduke, Elton, Downton, Black Eagle, Knight's Black and Frogmore Bigarreau. The fruit of Governor Wood, one of the best and most prolific varieties, was equally fine. Among the Peaches, *Violette Hative*, *Grosse Mignonne* and *Walburton Admirable* were the best, the Elruge and Downton Nectarines being well coloured. The Strawberries were very fine, a great number of varieties being staged, including Royal Sovereign, Gunton Park, Commander, Queen of Denmark, *Hélène Gloede*, *James Veitch*, *Bicton Pine*, *La Grosse Sucrée*, *Edouard Lefort*, *Monarch*, *Leader* and *Latest of All* (silver-gilt Knightian medal). The same exhibitor staged new Melons and a seedling Strawberry. The Melon named *Cambrian* was not at its best. The Strawberry named *Duke of Connaught*, though good, was thought to too closely resemble others in commerce. Messrs. Veitch and Sons, Ltd., Chelsea, staged dwarf Cherry trees in pots, a very pleasing exhibit, as the trees were cropping freely, the fruits very good and clean. The best varieties were Elton, May Duke, *Bigarreau Napoleon*, *Empress Eugénie*, *Royal Duke*, *Governor Wood* and *Nouvelle Royale*. Branches of Cherries bearing very freely were shown, the varieties being *Black Heart* and *Frogmore Early Bigarreau*. Eighteen varieties of Cherries (gathered fruits) were staged, the best being *Guigne d'Annonay*, *White Heart*, *Adam's Crown*, *Belle d'Orleans*, *Mammoth*, and *Bigarreau de Schreken*. Twenty-four varieties of Strawberries were shown, including *Leader*, *Monarch*, *Gunton Park*, *Dr. Hogg*, *Royal Sovereign*, *Lord Napier*, *Empress of India*, &c. (silver Knightian medal). Messrs. Carter and Co., Holborn, sent forty varieties of Peas. There were very fine examples of *Danby Stratagem*, *Early Morn*, *Model Telegraph*, *Model Telephone*, *Duke of Albany*, *Gradus*, *Duke of York*, and several seedlings (silver Banksian medal). Two fine stands of *Black Hamburg Grapes*, beautiful berries and grandly coloured, were sent by Mr. G. Lane, Highfield Gardens, Staines (bronze Banksian medal). Melons were shown by several exhibitors, but no awards were made. One sent by Mr. W. Coates, Gorrington Gardens, Llanfairfechan, was a splendid fruit, but much past its best. Messrs. Laxton Brothers, Bedford, had a promising new Strawberry named *Fillbasket*, but not nearly ripe. *Leader* was also staged, and in fine condition, as was *Mentmore*. Mr. Bain, Burford Lodge Gardens, Dorking, sent *Peach Royal Charlotte*, very fine fruits from a tree thirty years old. The *Loganberry* was sent by Messrs. Kelway and Son, Langport; this was given an award last year. Peas of splendid quality were sent by Mr. Eckford, Wem, Salop, the best being *Wem Giant* and *Prior*; these two the committee desired to be sent to Chiswick for trial. Other kinds of a large size and good shape were *Ideal*, *Imperial*, and *Precocity*. Messrs. Cannell and Sons, Swanley, sent a nice collection of Peas, *Lord Mayor*, *Duke of Norfolk*, *Gradus*, *Talisman*, *Epicure*, *Bynsford*, and *Reliance* being very fine. Dried vegetables in variety were sent by Mr. Maries from the gardens of the Maharajah of Gwalior, India. This was an interesting exhibit, but the vegetables when soaked for cooking, especially the Cauliflower, had an unpleasant smell. Messrs. Laxton sent a fine dish of their new *Thomas Laxton Pea*, given an award of merit at Chiswick last week.

Meeting at Chiswick.

This committee met on the 5th to examine Peas, Strawberries and Lettuce. Several new Strawberries were examined, but in most cases the crops were very poor, and a fair test could not be obtained of their cropping qualities. Awards of merit were given to the following:—

STRAWBERRY REWARD.—This was a splendid fruit as regards flavour. It is not large, but of a bright colour, conical in shape. It is a mid-season fruit and stated to be an excellent cropper. The plant is a medium grower and has stout fruit-stalks. From Messrs. Laxton.

LETTUCE CRYSTAL PALACE.—An excellent Cabbage variety, leaves fringed and curled, slightly coloured at the edges. Evidently a grand summer variety.

PEA ACME.—An early 3 feet variety of very fine flavour. This Pea is the result of crossing *Stratagem* with *Veitch's Early*, and will be a valuable addition to the earliest section, the haulm being strong and the pods medium-sized.

PEA THOMAS LAXTON.—A 5-foot variety with large deep green pods tightly packed with large Peas. It is a very free bearer, the haulm being laden with pods to the soil. It is a second early with a larger pod than *Gradus* and equal in quality. From Messrs. Laxton Bros.

PEA DRUMMOND'S NEW.—A very fine variety, not unlike *Ne Plus Ultra* in colour and flavour, but dwarfier. It has a large pod and is a very free bearer.

Other Peas were examined, and in most cases they were most disappointing, having made poor growth and few pods. Evidently the soil was at fault, but we see no reason why good Peas cannot be grown at Chiswick as in previous years. Mr. Beckett, Aldenham House Gardens, Elstree, sent some splendid *Thomas Laxton Peas*. This variety received an award and is described above. Mr. Geo. Bunyard, Maidstone, sent some patent fruit sieves in two sizes (bushel and half bushel); these are round and made with strips of wood, and amply ventilated. The sieves do not bend or give in the same way as baskets, so that the fruit does not get bruised. The committee wished them to be given a trial at Chiswick this season. They are of Russian manufacture. Messrs. Bunyard use them largely and like them very much. Messrs. Laxton Bros., Bedford, exhibited a new Strawberry, *Thomas Laxton*, a very promising fruit, the result of crossing *Jas. Veitch* and *Royal Sovereign*. The fruit was not unlike that of *Jas. Veitch* and was not at its best. A fruiting plant and fruit also were sent of *Mentmore*, a variety given an award of merit last year at Chiswick. The fruit, though of splendid colour and size, lacked flavour on this occasion, doubtless owing to the cold winds.

Roses.

The special Rose show postponed from the 28th ult. to the present meeting was in every sense a success, and the blooms regarded as a whole of the finest possible quality. Competition was also exceptionally keen in the best classes, there being sometimes as many as twenty competitors. In the class for eighteen single trusses (amateurs), distinct, Mr. O. G. Orpen, Hillside, Colchester, came well to the front, his blooms possessing rare quality and finish, which with size and colouring easily carried off the chief honours. His best blooms were *Kaiserin Augusta Victoria*, *Mrs. W. J. Grant*, *Ulrich Brunner*, *Mrs. Sharman Crawford*, *Cleopatra* (a really superb flower), *Helen Keller*, *Mme. Hoste*, *Mrs. John Laing*, *La France*, and *S. M. Rodocanachi*, the rosy cerise petals of this last being delightful. Mr. T. B. Haywood, Woodhatch Lodge, Reigate (gardener, Mr. Salter), was second with capital examples of *Caroline Testout*, *La France*, *Duke of Wellington*, *A. K. Williams* (finely coloured), *S. M. Rodocanachi*, *Her Majesty* (a rather young bloom of grand size and build, showing well the fine pink shade), *Merveille de Lyon*, *Mme. G. Luizet*, *Marie Baumann*, a fine bloom of *Pride of Waltham* (a rosy peach shade), &c. Mr. C. J. Grahame, Leatherhead, was third. For eighteen single trusses (open) Messrs. D. Prior and Son, Colchester, took the first prize, having good *La France*, *Mrs. Grant*, *S. M. Rodocanachi*, *Lady Mary Fitzwilliam*, *Horace Vernet*, *Maman Cochet*, a charming flower; and *Helen Keller*. Messrs. Frank Cant and Co., Colchester, came second with *Duke of Connaught*, *Her Majesty*, *Captain Hayward*, *Duke of Edinburgh*, *Marchioness of Londonderry*, *Marquis Litta* and others, Messrs. Paul and Son, Old Nurseries, Cheshunt, being third. For twelve single trusses, distinct (amateurs), the first prize went to Mr. E. Mawley, Rosebank, Berkhamsted, the finest blooms being *Beauty of Waltham*, *Mrs. Paul*, *La*

France, Mrs. Grant, Caroline Testout, very fine; Ulrich Brunner and S. M. Rodocanachi; Mr. Alfred Tate, Downside, Leatherhead, who set up handsome flowers of Kaiserin Augusta Victoria, Duchess of Bedford, La France, S. M. Rodocanachi, &c., being second, with the Rev. A. Foster Melliar, Sproughton Rectory, Ipswich, who had good blooms of White Lady, Mrs. Grant, Her Majesty, Innocente Pirola, Francois Michelin, &c., third. The class for six single trusses, distinct (amateurs), brought a goodly lot of blooms, the leading prize being won by Mr. G. W. Cook, The Briers, North Finchley, with fine Mrs. Sharman Crawford, Earl Dullerin, Mrs. Grant, Francois Michelin, &c., Mr. F. J. Thompson, Laurels, Bounds Green, being second with Her Majesty, Kaiserin Augusta Victoria, La France, Ulrich Brunner, and others in good form. For nine single trusses of any one variety of H.P. or H.T. (amateurs) the first prize went to Mr. T. B. Haywood, Woodhatch Lodge, Reigate, for a fine lot of Mrs. Laing, the second prize being secured by Mr. C. J. Grahame, Leatherhead, who set up Mrs. Laing and an optional lot of Kaiserin Augusta Victoria, the latter variety being also used by Mr. O. G. Orpen, Hillside, Colechester, who secured the third prize. For six trusses of any one variety of H.P. or H.T. (amateurs) the first prize was obtained by Mr. G. W. Cook, North Finchley, for fine blooms of Mrs. John Laing, the same variety being staged by Mr. Alf. Tate, Leatherhead, and by Mr. E. M. Bethune, Horsham, who secured second and third prizes respectively. In this class there were no less than seventeen entries, and it says much for the popularity of Mrs. J. Laing to see it so freely used.

TEAS AND NOISETTES.—For eighteen single trusses, not less than twelve varieties or more than two trusses of any one variety, Mr. O. G. Orpen, Hillside, Colechester, was first with a magnificent set in the very pink of condition, his Caroline Kuster, Catherine Mermet, Corinna, Medea, Bridesmaid (a lovely soft salmon), Mme. Hoste, Comtesse de Nadaillac, Cleopatra, Mme. Cusin, Souv. de Elise Vardon, Maman Cochet, and Souv. de S. A. Prince being perfect models of beauty, Mr. E. M. Bethune, Deene Park, Horsham, who was second, having Medea, Caroline Kuster, Souv. de Therese Levet, Cleopatra in grand form, and an exquisite bloom of Comtesse de Nadaillac. For eighteen single trusses (open), Messrs. D. Prior and Son, Colechester, again took the leading place, having Jean Ducher, Mme. de Watteville, Corinna, Mme. Hoste, Ernest Metz, Maman Cochet, Innocente Pirola, and Comtesse de Nadaillac, the last three being of superb form, size, and finish, the second prize going to Mr. G. Prince, Oxford, who had Comtesse de Nadaillac, very rich, the centre almost full golden; Sylph, Niphotos, Maman Cochet, Souv. de S. A. Prince, and Innocente Pirola among his best. For twelve single trusses, not less than nine vars. (amateurs), the first prize went to Rev. V. H. Jackson, Stagden Viarage, Bedford, Ernest Metz, Mme. Hoste, Catherine Mermet, Comtesse de Nadaillac, Souv. d'un Ami, and Caroline Kuster being the best examples, the second prize going to Mr. J. T. Strange, Aldermaston, Reading. For six single trusses, not less than four varieties, Miss B. H. Langton, Raymead, Hendon, was first with Souv. de S. A. Prince, The Bride, Catherine Mermet, and Comtesse de Nadaillac as among the best; Mr. R. W. Bowyer, Haileybury College, Herts, being second with Mme. Cusin, Mme. de Watteville, Catherine Mermet, and Comtesse Nadaillac. For nine single trusses of any one variety (amateurs), Mr. O. G. Orpen, Hillside, Colechester, took the leading prize with a superb set of Souv. de S. A. Prince, Mr. C. J. Grahame being second. For six single trusses of any one variety, Mr. E. M. Bethune, Horsham, took the lead with a beautiful and uniform set of The Bride in fine condition, Rev. Foster Melliar being second with Souv. d'Elise Vardon, very fine in form and full.

GARDEN AND DECORATIVE ROSES.—Of the more freely flowered garden sorts there were several groups not for competition from leading firms,

notably those of Messrs. Paul, Cant, Turner, and others. These were all arranged in large handsome bunches, which together with the numerous buds made a fine display. The group from Mr. Chas. Turner, Slough, contained many good things, such as Alister S. Gray, a charming soft yellow; Perle d'Or, The Pet, Narcisse, a creamy lemon shade; Laurette Messimy, a lovely salmon-peach, in the bud, very pleasing; Crimson Rambler, Maiden's Blush, Bardou Job, very dark, and many beautiful seedlings only bearing numbers (silver Flora medal). Messrs. Paul and Son, The Old Nurseries, Cheshunt, had such kinds as Rosa Mundi in the way of York and Lancaster, Carmine Pillar, Mme. P. Cochet, Gustave Regis (a nankeen yellow), Coupe d'Ilbé, Royal Scarlet (a fine colour), Alister S. Gray, Camoens (rosy peach), Mignonette, Marquis of Salisbury (very intense shade), and Mosehata alba (a large pure white), being among the most attractive in this group, which included several Spiræas of herbaceous kinds, many Iris Kämpferi in large bunches, and a fine bunch of Orchis foliosa (silver Banksian medal). A very charming lot of these garden Roses came also from Mr. F. M. Campion, Colley Manor, Reigate (gardener, Mr. Joseph Pitt), including Paul's Single White, Rosa Mundi, Crimson Rambler, Bardou Job, L'Idéal, very beautiful in every way; Alice Gray, a fine white; W. A. Richardson, Mosehata nivea, a fine single white; Mme. Plantier, also white, though double and very free (silver Banksian medal). Lord Penzance likewise contributed a most fascinating lot of hybrids, amply illustrating the possibilities of crossing among these free-flowering sorts, among them several rugosa hybrids, with possibly some such blood as Carmine Pillar intermixed. Others included R. pomifera crossed with Jean Chérpin, which was very beautiful. A rose-scarlet kind, also a very dark variety, with a handsome single rose-pink, not named, attracted a large amount of attention (silver Flora medal). Messrs. Frank Cant and Co. had lovely masses of Mme. Faleot, Mme. Resal, Laurette Messimy, Céline Forestier, Gustave Regis, Rainbow, Camoens, W. A. Richardson, Souvenir de Catherine Guillot, Ma Capucine, Reine Blanche, Crimson China, and several beautiful Moss kinds all disposed in handsome bunches (silver Banksian medal). The only other exhibit of Roses was an extensive one of pot plants and cut blooms from Messrs. Wm. Paul and Son, Waltham Cross. This fine lot included dwarfs and standards, the former mostly H.P.'s, the latter Teas or Hybrid Teas, &c. Among dwarfs, Mrs. Sharman Crawford, Baroness Rothschild, Alfred Colomb, Xavier Olibo, Marchioness of Londonderry, Merveille de Lyon, Mrs. J. Laing, Crimson Queen, and Capt. Hayward all carried large handsome blooms, while among the standards were splendidly flowered examples of such kinds as Empress Alexandra of Russia, a most lovely shade and everywhere admired; Bridesmaid, Corinna, Caroline Testout, Marie van Houtte, Mme. de Watteville, &c., the drooping plants and their clustering flowers forming a canopy over those below, the front being fringed with an array of boxes filled with the choicest blossoms of Tea and other beautiful kinds (silver Banksian medal).

The weather in West Herts.—During the past week the day temperatures have been changeable, the highest reading in shade on two days being only 63°, while on several others it exceeded 70°. The nights were mostly cold for the time of year, and on that preceding the 11th the thermometer exposed on the lawn fell to within 4° of the freezing point. Both at 2 feet and 1 foot deep the ground is about a degree below the July averages for these depths. No measurable quantity of rain has now fallen for nearly a fortnight, but the percolation has not yet quite ceased through either gauge. The winds, which were light, have come almost exclusively from some northerly point of the compass. The record of bright sunshine proved

poor for a summer month, averaging less than five hours a day. E. M., *Berkhamsted*.

NOTES OF THE WEEK.

The Narrow Water Gunnera manicata.—The particulars as to the dimensions are: total width at ground from tip to tip of leaves, 35 feet; height in centre, 12 feet; number of leaves, 78, without counting a number of small ones from secondary crowns.—T. SMITH.

Lilium Hansonii.—This is one of the finest Lilies from a garden point of view where freedom of flowering with good habit and easy culture is concerned. It is specially suited to grouping with a free hand, and when associated with other things, such as dwarf shrubs on the grass or the like, is seen to better advantage.

Dianthus cæsius is perhaps the best known and possibly the commonest of the Pink tribe, yet one of the most beautiful by reason of the delicate pink blossoms that practically cover the dense cushion of leaves. It is a pretty plant, too often absent from those positions that suit it best, viz., such as are warm and dry, where it grows and blossoms with all its wonted freedom.

Hydrangea paniculata grandiflora.—The handsome plume-like panicles of this plant when gently forced render it among the most useful of shrubby plants that are suited for the decoration of the greenhouse. The plant is so easily grown by the ordinary methods, that it should find its way, even if in limited quantity, into various arrangements where bold subjects are required.

Flowers from Winchmore Hill.—I send you some flowers of seedling Heléniums, three of which I consider first-class plants, viz., H. grandiflorum var. Beauty (1½ feet), H. g. var. Golden Queen (2 feet), H. pumilum magnificum (2½ feet). This last is the finest of anything in this way. I also send H. grandiflorum (type), H. pumilum and H. Bolanderi, which runs H. pumilum very close.—AMOS PERRY.

Thalictrum tuberosum.—So very few of the members of this genus are of any value in a cut state, that the above is worthy of mention from this standpoint alone, the flowers being pure white and each about half an inch across. Associate it with this is the elegant habit of the dwarf Meadow Rue, such as T. adiantifolium, &c., the compact habit of growth, which is rather under 2 feet, being all that could be desired.

Campanula punctata.—There is a distinctness about the spotted Bellflower that is not the accompaniment of every species or variety, the exceptionally long pendent white flowers—more than ordinarily attractive—being freely, though delicately spotted near the base of the corolla on the inner surface. So worthy a plant should more frequently be grown. It is well suited to the rock garden or border in good loamy soil.

A pretty combination of leaf and flower occurs in my garden. A large plant of the white-leaved *Euonymus japonicus*, which covers a north wall for some distance, is wreathed with sprays of *Tropæolum speciosum*, and the effect is charming. Close to it is a plant of Garry elliptica, over which the *Tropæolum* rambles equally freely, but the flowers are far less effective against this green background.—S. H. B., *Leadbury*.

Allium kansuense.—Although the Alliums are not favourite flowers, there are several species well worth growing. A pretty and distinct little Garlic has been growing here under the name of *A. kansuense* for several years. It grows only a few inches high, has steel-blue flowers, and increases but slowly. The flowers are drooping, and the plant is well adapted for growing in the rock garden.—S. ARNOTT, *Carsethora, by Dumfriesshire, N. B.*

Gloxinia Her Majesty.—This is undoubtedly the best white among these increasingly popular flowers, the large handsome blossoms, often from 4 inches to 4½ inches across, being as remarkable for their exceeding purity in all their varying stages as for the great vigour of the stems. The flowers are bold and erect, and the massive foliage drooping over the pots singularly small for the size of the plant. A large batch of this hand-

some kind is now in perfection with the Messrs. Sutton and Sons, Reading.

Buddleias.—The species *B. globosa* is very common in gardens about here, and the height of 20 feet is not at all unusual. *B. Lindleyana* occurs in several good gardens under protected verandahs, and is often 15 feet or more high, though Nicholson gives its height as 6 feet. I had a plant of *B. globosa* against a west wall in my garden at Tonbridge, in Kent. It flowered well for eight years, until a frost came, which was just too much for it and killed it to the roots.—W. THOMSON, *Bishop's Trington, N. Devon.*

Campanula cenisia.—Among the rarer Bell-flowers this is worth a place by reason of its distinct colour as much as its equally distinct habit of growth. The species, however, is not so easily grown as some kinds, but if given a good position in the rock garden, in a narrow, though deep chink of gritty loam, it usually holds its own. A surface mulching of small stones not only stays over rapid evaporation, but likewise prevents the plants being lifted by frost or worms—the former a great impediment to the success of many good alpine flowers.

Lupinus arboreus.—The tone of soft yellow in this well-known plant renders it exceedingly popular not only in the garden, but in a cut state, and for the combined uses named it is worthy of inclusion in any collection of hardy free flowering plants. The plant is likewise well suited to making a sort of garden fence, and in this way even when not in flower the silvery grey tone of its foliage renders it distinct and effective. Large isolated groups, too, have a very distinct appearance, while its profuse flowering commends it to all.

Antirrhinum Yellow Prince.—Even a solitary plant of this handsome self yellow Snapdragon would suffice to portray the beauty as well as the value of such a sterling variety as this. At the same time we were not prepared recently in a hurried glance through the seed trial grounds at Reading of Messrs. Sutton and Sons to meet something like an acre or more of this fine yellow Snapdragon. In its freedom of growth and dwarfness are combined with freedom of flowering and earliness. The first flush of beauty had, however, passed, thus showing even early in July its claim to early flowering.

Campanula grandis alba is a very old and showy, if much neglected, border plant that is now in full bloom. It is scarcely possible to imagine a purer mass of colour than a large group or bed of it with dozens of the snow-white spikes about 2½ feet in height. The hardy, vigorous nature of the plant fits it for association with quite strong-growing subjects, and if at times it is apt to cover too much space this is easily remedied. The blue form is equally good in its way, and where for varying reasons the forms of *C. persicifolia* are not a success the above plant will be found a good substitute, and not so liable to fail in hot, dry seasons.

Iris Leon Tolstoi.—The "English" Irises have been very beautiful here this season, and among the dark varieties none have been so much admired as this grand one which was figured in THE GARDEN some time ago. The flowers are very large and dark blue purple. It has looked exceedingly well, springing from a carpet of glowing orange Californian Poppies (*Eschscholtzias*), which follow the Snowdrops which in the early year flower in the same spot. Fine as are these Irises, there is yet room for improvement from seed. Some pretty varieties have appeared here among seedlings, but none have been named.—S. ARNOTT, *Carsethorn, by Dumfriess, N.B.*

Walker's hybrid Lychnis.—This hybrid between *Lychnis* or *Agrostemma coronaria* and *L. Flos-Jovis* is at present in full bloom, and is very effective with its bright scarlet flowers. *Agrostemma Walkeri*, as it is generally called, resembles to some extent both its parents, and is an acquisition to the garden. It is practically a biennial, although it occasionally survives after flowering. It produces seed, but this is not to be depended

upon to come true, and generally reverts to one or other of the parents. *A. Walkeri* was raised at Chester, and was sent out by Messrs. Dicksons of that city. Similar hybrids have appeared elsewhere.—S. ARNOTT, *Carsethorn, by Dumfriess, N.B.*

The Shipka Broom (*Cytisus Frivaldskyanus*).—Under this name (which is even more un-musical than another it is known by, viz., *C. schipkaensis*) we now have in flower a Broom which promises to be a very useful addition to the group of dwarf kinds. It is a native of the Balkans, and was found only a few years since on the Shipka Pass. It first appeared in this country three or four years ago, but now it has become established it shows itself to be a better thing than was thought probable at first. It is about 1 foot high at present, and bears its flowers in an umbel or head at the end of each shoot. They are white with a yellow tinge, and the plant is quite distinct from any of the Brooms now in flower. Of the well-known older species, *C. capitatus* most resembles it. Its value is increased by flowering as late as this, when most of the Brooms are past.

Notes from Cranbrook.—*Ostrowskia magnifica* has opened one flower here for the first time. To judge from it, anything more unworthy of such a name cannot be conceived. Callas in a foot of water, where they have been for some years, are luxuriant. Little Gem in about 6 in. of water is, I think, more free-growing and satisfactory than any of them. *Iris Kämpferi* is just coming out. I think it does best just above the water-line, but I have plants in 6 inches of water which flower well and increase in size. The Water Lilies are fully a month late; sunless days and cold nights have chilled the water. *Verbasicum olympicum* is a glorious sight, and the self-sown Foxgloves of all shades quite take the place of the flowers in the Rhododendron beds. The various climbing single and cluster Roses and Sweet Briars filling the hedges show how easily these necessary evils may be made beautiful.—MEDWAY.

The Mocassin Flower at Straffan.—Your note in last week's GARDEN on the Mocassin Flower (*Cypripedium spectabile*) here has one error. For fine dry clumps, read "five dry clumps," which would give the rate of increase, which is the most interesting part of the note; otherwise, readers would think that the whole twenty four plants had been imported.—FREDK. BEDDARD.

—I was pleased to see the note on this by Mr. Burbidge, and shall be pleased if Mr. Bedford will accede to his request and give us particulars of his treatment. It was not in flower when I visited Straffan, but the plants were exceedingly fine and the flower-buds gave promise of the remarkable display they have since made. What is more, they were not planted in a bog, nor had they apparently received any treatment beyond the means of those possessing a good flower border. No doubt Mr. Bedford has cared for them and catered for their wants well, but it puzzles one to account for his success under the conditions under which they grow.—S. ARNOTT.

Rhododendron (Azalea) occidentale.—Now that all the evergreen Rhododendrons and nearly all the Azaleas are over for this year, the value of this shrub becomes all the more apparent. It was at its best during the latter half of June, but is still well in bloom. It is, of course, now fully in leaf, and embowered in its luxuriant bright green foliage are its large clusters of flowers. These are mainly of a pure white, but have a blotch of pale yellow on the upper side. Not only are they beautiful to look at, but they also fill the air around with a most charming fragrance, equalling in this respect the old *Rhododendron flavum* (better known as *Azalea pontica*). The species is a native of the western side of the Rocky Mountains, and is the only Azalea in cultivation from that part of North America. It has been in cultivation for upwards of fifty years, and has lately been hybridised with the earlier varieties by Mr. Waterer, of Knapp Hill, with a

view to lengthening the Azalea season. The results already achieved are very promising.

PUBLIC GARDENS.

A new park for Queensferry.—The Earl of Rosebery has presented to the inhabitants of Queensferry a large piece of land to the east of Kirkliston Road, to be used as a public recreation ground.

Public gardens and the study of botany.—A letter was received from the London County Council, stating that the Parks and Open Spaces Committee had considered the Board's letter of May 24 last, which enclosed an extract from a report from the British Embassy at Berlin, as to the arrangements in force in that city for facilitating the study of botany, and which asked the Council whether a somewhat similar arrangement could not be made in London. The County Council informed the Board that they were taking steps in this direction by forming a series of beds in Battersea, Ravenscourt, and Victoria Parks, with specimens of plants in their natural orders, and added that the Parks Committee thought that it would be desirable to see the result of this experiment before proceeding any further for the present.

Open spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., Lord Teynham, deputy-chairman, presiding, it was reported that since the last meeting the garden which the association laid out in York Street, Walworth, and the Central Park and drinking fountain, East Ham, had been formally opened to the public. It was agreed to undertake the laying out of a disused burial ground in Hoxton, the enclosure at Portland Place, New Kent Road, and some small City churchyards, provided that proper arrangements were made in each case for maintenance. In response to the appeal of the association, a reply was received from the Rev. Harry Jones, the rector, to the effect that so far as he was able he had, in giving up a strip of the churchyard of St. Peter Cheap for the widening of Wood Street, safeguarded the existence of the fine Plane tree at the corner of Cheapside and Wood Street. It was agreed to communicate with the Corporation asking that body to take care to do nothing which would injure the roots of this unique tree.

Galvanised iron for stages.—Will someone who has used galvanised iron for stages in a stove instead of slates give some information as to durability, with damp cinders, &c., on them, and moisture continually about?—FOURMART.

Making a water tank.—Will any reader of THE GARDEN kindly inform me the best and cheapest way to make a tank about 8 feet in diameter and 3 feet deep? I am making a new kitchen garden, and require it in the centre to hold water.—W. C.

Name wanted.—Can any reader give me any information as to what plant the term "Lily of Yarrow" is applied? I have been given to understand that the plant in question is of a blue colour, highly scented, and a native of the backwoods of America.—W. S. T.

THE MARKET GARDEN.

STRAWBERRIES IN KENT.

For the past few weeks the Strawberry season has been in full swing. Strawberries, like all other Kentish fruits, have their own favoured locality, and it is within comparatively easy distance of the metropolis that the majority are grown. In private gardens Strawberries are frequently subject to a good deal of coddling, often without the best results, but the acres of fine fruit grown in Kent under field cultivation prove that given a suitable soil and situation, with other conditions favourable, Strawberries of the finest quality can be and are produced in tons from the open fields. At the same time they demand good cultivation, and the growers who are the most liberal in matters of manure and labour usually reap the best harvest.

When recently in the neighbourhood of Swanley I noticed many fields, and amongst them a large field on a sloping hillside. Clean white straw had been carefully placed between the rows and worked round the plants for the purpose of keeping the fruit clean. On this the luscious, fresh-looking berries rested, and in the sunshine their bright colour showed up in an attractive manner. The most popular Kentish Strawberry is still Sir Joseph Paxton, no doubt on account of its bright appearance and good travelling qualities. In choosing varieties the market Strawberry grower has to consider three important points, viz., appearance, suitability for travelling and flavour. One would naturally think the last would be the first consideration, but such does not appear to be the case. The public prefers something that pleases the eye, and the large bright appearance of Sir Joseph Paxton attracts the attention of purchasers before another variety not possessing these qualities, though better in flavour. Again, Sir J. Paxton is a good traveller, which is evident from the fact that tons of Kentish fruit are put on rail near their native

fields and despatched direct to Manchester, Liverpool, Glasgow and other great centres in the north, where they arrive in a sound condition. This variety is also a sturdy grower and free cropper, two important essentials, and when we also consider the tendency of sticking to a well-tried sort like this in preference to speculating with others of recent introduction we have the chief arguments in favour of Sir Joseph Paxton as a market Strawberry. Though the variety mentioned holds its own, there are others making headway, and doubtless the foremost amongst them is Royal Sovereign. I have had frequent opportunities of obtaining the opinion of growers respecting this variety from a market point of view, and with scarcely one exception the replies have been most favourable. On many farms it is now grown largely and bids fair to become a keen competitor for premier place with the older variety. In the first place Royal Sovereign is early, and this is essential. Growers who make a point of forcing and also of picking the earliest outdoor fruit for dessert speak highly of Royal Sovereign, which is generally ripe some days before Sir J. Paxton, and as the first fruit in the market has an important bearing on the returns, this is a recommendation. Noble is another variety more or less popular among market growers, but there appears to be a diversity of opinion in regard to its qualities as a market fruit. Some growers speak highly of it and grow the variety largely, while others again complain of its woolly flavour and indifferent cropping. Other varieties are grown in less quantities, but the list is confined to the above-mentioned sorts. The Kentish Strawberry grower, however, is no bigot, and is generally ready to give any variety a trial that is likely to suit his purpose.

The advent of the Strawberry season introduces an air of activity into districts where the fruit is grown extensively, and as the majority of Kentish Strawberries are produced within comparatively easy distance of London a great many of the pickers hail from the densely-

crowded streets of the metropolis. Growers have long since learnt the importance of getting the fruit into the market early, and long before half London is awake the light spring drays piled up with round hampers of fruit picked the same morning are on their way to Covent Garden. Before the trains come in, the first consignments have been despatched by dealers to all parts of the metropolis. When the first streaks of light break over Kentish fields the pickers turn out under the supervision of a foreman, the piles of round hampers are filled with fruit, and in a few hours are on their way to the market. In districts lying further from London the fruit has to be sent by rail, and from some stations many tons of fruit are despatched during the season. Growers of a small quantity of Strawberries in private gardens have no idea of the magnitude of the traffic in this fruit, most of which is confined to Kent. The demand is always great, and prices vary according to supply. Late frosts often have disastrous effects on the Strawberry crop, but when natural conditions are favourable those who are the most liberal in matters of cultivation invariably obtain the best returns.

The period over which a plantation will continue in good bearing depends largely on the treatment, and, though three or four years is the average time under high cultivation, Strawberries will continue to bear much longer. Good clean straw is the best material for placing round the plants before the fruit ripens, and, though for the sake of economy other material is sometimes used, the result is not satisfactory, particularly in damp weather, owing to the wholesale rotting of the fruit. Most growers raise their own plants for new plantations, and, though this work cannot be done with quite the same care as is usually practised in private gardens, the importance of obtaining strong early runners and planting them in time to become established before the winter sets in has been proved over and over again, and the most successful growers are careful in paying attention to this. After picking is over there

is much to be done in the Strawberry fields. Removing the runners, cleaning the plants, cultivation between the rows, and feeding with natural and artificial manures are all included in the routine, so that next season's crop may be ensured so far as the grower is concerned.

G. H. H.

ORCHIDS.

COOL ORCHIDS IN FRAMES.

THERE are many beginners in Orchid culture that have only one house wherein to grow their plants, and naturally like to have as much variety in their small collections as possible. It is surprising what a number of species may be wintered in one house: Cattleyas and Laelias from the Brazilian forests, Odontoglossums and various others from Mexico and Guatemala, many of the West Indian Oncidiums, and a large number of Vandas, Dendrobiums and Cypripediums from the Old World habitats. The list, in fact, is a very long one, and includes the majority of the showiest and most beautiful of Orchids. But in summer a large proportion of the plants would be difficult to manage successfully. The most of those named may by judicious arrangement and careful treatment still be included, but none of the truly alpine kinds from Peru and New Grenada, the Masdevallias, cool Oncidiums and Odontoglossums, will long continue in health if subjected to the temperature relished by Cattleyas and Dendrobiums. They will not withstand the same amount of sun, while if the house were sufficiently ventilated for them the atmosphere would prove too dry. But if a well built pit or even a few frames are provided, all these lovely species may be grown with the greatest ease. When different frames or compartments of a pit can be set aside for them the probability of succeeding is still greater, as such species as Lyncaste Skinneri and others, Maxillarias in variety, and the grande, citrosinum and others of the warmer Odontoglossums can be kept distinct from Masdevallias and Disas, Restrepias and Odontoglossums of the crispum set. A small or large compartment, according to the stock of plants may be set apart for Cypripediums of the insigne, villosum and venustum types, these species and their varieties doing well in summer in any fairly moist and shady frame.

When the ordinary wooden box frame is to be used, something should be done to prevent slugs and snails entering. A layer of sharp ashes and soot is a preventive to some extent, and if it can be managed a better way is to stand the frames on a zinc or stone tray holding an inch or so of water. Or these may be made to fit the inside of the frame and the plants be staged thereon. These or other methods that will occur to anyone interested may be supplemented by careful watching at night with a lantern, or trapping in Lettuce leaves or scooped-out Potatoes, and one of the most troublesome details will be overcome. If the plants can be placed in a shady part of the garden all the better; the position will be naturally cooler and less shading will be necessary. The amount necessary will, of course, depend on the species grown, but the greater number of cool-house kinds like plenty of shade during the summer. In all other details the culture of the plants is precisely the same as for others grown in the usual cool house; ventilation and watering, cleaning and attention to atmospheric moisture all needing care.

Regarding the season that they may be moved to the frames, it is good policy to get them out

as early as possible after the middle of April. Sometimes it is very cold at night just at this time, frosts and cold winds being the rule, and in this case the plants will be safer in the house a little longer. When taken out, covering the glass at night will be necessary, at least until the middle of June in ordinary seasons. The reason for taking them out early is that the other occupants of the house can afterwards be properly treated as to temperature. They may remain in the frame until September at least, and in some seasons it is quite safe to leave them out as late as October and early November. When taken back to the house they should be arranged in the coolest part.

Masdevallia Peristeria.—This handsome species varies a good deal in size, a flower of a good form of it, measuring about 5 inches across, being now open. The striking part of the flower is the centre, where lip and sepals form a resemblance to those of the Dove Orchid, hence the specific name. The flower is greenish externally, the centre purplish-brown, owing to the number of small hair-like processes upon it. It is a native of various parts of New Grenada, and was introduced in 1873.

Chysis lævis.—The flowers of this species, each upwards of 2 inches across, are produced in racemes of about a dozen flowers on the strongest plants. The ground colour is a brownish yellow, the lip prettily spotted with red. It may be grown either in the Cattleya house or the East India house, an important point being to get the growth well ripened in autumn, as it will not bloom satisfactorily unless the old pseudo-bulbs are well hardened. The foliage at first is soft and is always liable to insect attacks, red spider being especially partial to it. A sound compost of equal parts loam fibre, peat, and Sphagnum Moss suits the stronger plants well. Water must be freely given at the roots as long as the growth is active, a greatly lessened supply being necessary while the plants are at rest during winter.

Oncidium Harrisonianum.—It is strange that this beautiful little species is not more often met with, as it is so distinct and pretty. The peculiar glaucous-grey tint of the foliage and bulbs distinguishes it from all others, and the paniced inflorescence is unlike that of the majority of Oncidiums. The colour is yellow, spotted with red on the sepals and petals, and a fine crest on the lip. On account of its small tufted habit a large pot is unnecessary, but I like pans or pots better than blocks or baskets. The small pans pierced at the sides are excellent for it, the roots obtaining abundance of air through these holes, an important point with epiphytal plants. Grown in an ordinary description of compost the plants do well, and flower annually in a house such as suits Sophronitis or any of the grande section of Odontoglossum. They like plenty of light, and will stand more sun than cool Orchids generally. It comes from various parts of Brazil, and first flowered in this country in 1832.—H.

Vanda Denisoniana.—The pure white flowers of this beautiful Vanda are always attractive, and it is only too little grown. The lip is singularly formed and has a narrow front lobe and erect side lobes, the blossoms appearing about a dozen or so upon a spike. Like many of the smaller-growing Vandas, it dislikes a great body of heavy material about the roots, and is, in fact, well treated if potted or basketed like *V. cœrulea*. In quite small receptacles nice specimens, carrying several flower spikes, may be grown, and they are splendid for grouping or the spikes are fine for cutting. The compost may be the usual Sphagnum and charcoal as advised for distichous-leaved kinds generally, the drainage and other material being scrupulously clean. It delights in warmth and a very moist atmosphere while making its growth, this latter being provided by frequently damping down the stages and floors rather than by overhead syringing. Occasional light dewings are

helpful, especially during the afternoon of hot summer days, but regular syringings are not advisable. *V. Denisoniana* grows naturally on the Arracan Mountains, where it was discovered by Colonel Benson about 1868.

MASDEVALLIA CAUDATA HYBRIDS.

This section is suitable for basket or pan culture, as they certainly thrive more satisfactorily when suspended near the roof glass. They are a distinct, desirable, and easily cultivated class of hybrids, requiring through the warm months of the year similar treatment as regards temperature and moisture as the cool section of Masdevallias. During the winter it is not desirable to allow them to have a temperature less than 50°, or they are liable to get spotted. The best time to repot these is about the end of August, using fibrous peat and living Sphagnum, two parts of the former to one of the latter, pressing the compost moderately firm about the roots and base of the plants.

M. SHUTRYANA (*M. caudata* × *M. Harryana*).—This is one of the prettiest hybrids of this section, the flowers produced on scapes about a foot in length. The flower has the triangular characteristics of *M. caudata*, enlarged and flattened by the influence of the stronger growing parent. The colour is bright rose, slightly veined and suffused at the base with a darker shade of colour; the tail nearly 3 inches in length, bright yellow; the miniature lip rose with a blotch of purple on the apex, the side lobes white. It is a lovely free-flowering variety of good constitution and worthy of every consideration. It was raised in Sir T. Lawrence's collection.

M. CHAMBERLAINIANA was raised in the High-bury collection from the same parents. It is superior in many respects, being brighter in colour and altogether larger.

M. COERTAUDEIANA (*M. caudata* × *M. rosea*).—Although not possessing the robust constitution of the last named variety, this is a distinct and lovely form, having the intermediate characteristics of both parents both in growth and shape of the flowers. The interior of the lower sepals is bluish-white with several prominent rose lines, the upper sepal half yellow with several bright purple lines, the tails greenish yellow, the lip white with purple blotch in front, the exterior yellow, spotted and suffused with rose-pink. It was raised in the nurseries of Messrs. F. Sander and Co.

M. CAUDATA ESTRADÆ.—This, raised from the species indicated in the name by Mr. Seden in Messrs. Veitch and Sons' nurseries, is a dwarf-growing and free-flowering hybrid, with the intermediate characteristics of both parents. In shape it takes after *M. caudata*, with the bright colouring of *M. Estradæ*. The lower sepals are white, suffused from the centre downwards with bright rose-purple, the upper sepal creamy yellow lined and suffused with bright purple, the lip white, spotted with distinct rose, the side lobes white, the tails of the sepals bright golden yellow.

M. GELENGANA (*M. caudata* × *M. xanthina*).—This hybrid has the dwarf characteristics of *Masdevallia xanthina* and is best suited by a position near the roof glass. The lower sepals are creamy yellow, thickly covered with rich purple spots, the upper sepals yellow, lined and suffused with brown-purple miniature spots. The tails are bright yellow, the lip rose, spotted with purple. It is a most distinct and desirable variety, free flowering, and has a good constitution.

M. POURBAIXI (*M. Veitchi* × *M. caudata*).—The sepals are bright yellow, spotted and veined with dark purple, the tails rich purple, the lip yellow, suffused with purple, and a rich purple blotch on the disc. It is a distinct and desirable hybrid, worthy of every consideration.

M. KIMBALLIANA, raised from the same parentage as *M. Pourbaixi*, was introduced through Messrs. F. Sander and Co., St. Albans. It differs

slightly in colour from the last-mentioned hybrid, but the general characteristics are very similar.

M. HENRIETTE (*M. ignea* *crubescens* × *M. caudata*).—This is a pretty form, somewhat resembling *M. Shuttaryana*, but having more orange and tracings of the purple lines as seen in *M. ignea*, is very distinct. It has the triangular characteristics of *M. Shuttleworthi*, and is about intermediate between the two species both in habit of growth and in the flowers. It was raised in Mr. Ames's collection in America.

STELLIS.

CATTLEYA WARNERI.

This species is less variable than many others of the labiata set, but where a fair number of plants are grown there will be considerable difference in the flowers. Both in its manner of flowering and the shape of the blossoms it comes nearer to the true *Cattleya labiata* than any of the others, and its culture is in some respects similar. The growth starts in spring, the flower-spikes being produced upon it at once, the flowering season being extended over a longer or shorter period according to the number of plants grown. *C. Warneri* cannot be described as a difficult plant to cultivate; indeed, when healthy and well established the growths come away with considerable freedom, but it is a plant that it is wise to keep in health when it is so, for it is not easy to bring it back when it gets badly shrivelled or spotted. Occasionally *C. Warneri* is found difficult to flower freely, and as often as not this is the result of keeping the plants too much shaded. The most free-flowering plants are those grown in baskets suspended not far from the roof glass, but this is not always convenient, and in a light position they will do well in pots. If the basket treatment is practised, let them be large enough to take the plants comfortably and allow of root extension. The same with pots, the roots disliking a large pot, while they must not be too much pinched.

The present is a good time to repot or rebasket any plants that have flowered, taking them in hand directly the blossoms are past, as by this means the emission of roots which takes place now will help to establish them in the new material. The same with plants that for any reason have missed flowering. Very late blooming plants may with advantage be left over until spring if not badly in need of new material. I have repotted *C. Warneri* as late as September, but possibly at this date no great advantage over spring potting accrues. If the plants keep well to their seasons the cultural routine otherwise is much the same as for *C. Gaskelliana* and *C. labiata*. In the best forms of *C. Warneri* the flowers are each upwards of 7 inches across, the sepals and petals a pretty bright rose with a suffusion of purple, the lip usually of a deeper tint with a very deep amethyst purple blotch in front; the throat yellow with lines of rosy purple. Its variety *imperialis* is a splendid *Cattleya*, and there are others which might be named. The first time it flowered in England was with Mr. Warner, of Chelmsford, to whom it is dedicated.—H. R.

Laelia crispa.—I have just flowered a lovely form of this old Orchid, quite a superior thing to the usual varieties. The flower is as large as that of a good *L. purpurata*, the characteristic fringed lip being very beautiful. It has the front portion of the richest crimson-purple imaginable, shown up well by the golden yellow tint on the inside of the lateral lobes. The intensity of the colouring is remarkable, and should it prove constant it will be a splendid variety. The plant is a fine one, and was purchased as an unflowered specimen. Even the old forms of *L. crispa* are well worth growing for their brightness and free-flowering nature, and it is one of those useful old species that are not thought sufficiently of now-a-days. Culturally, its requirements are much the same as those of *L. purpurata*, and the stronger it can be grown the better. The usual *Cattleya* house tempera-

ture suits it admirably, and being very strong rooting the compost in every case must be very rough and open over good drainage. It is well if possible to keep it at rest after flowering, but this is not always easy, and, rather than force it to rest, it is better to let the plants have their own way. Some will be found to keep naturally to their proper season, while others will not. A free supply of moisture is necessary while growing and until the flowers are past and the pseudo-bulbs complete, rather less sulking in winter.—H. R.

Oncidium Lanceanum.—Very beautiful now are the flowers of this *Oncidium*, the deep chocolate-brown markings on the yellowish green ground and the various tints of rose upon the labellum making an unusual and very taking combination of colour. It belongs to the section of the genus without any pseudo-bulbs, the plants consisting of large deep green, purple spotted leaves. The flower-scapes appear in early summer at the base of the newly-formed leaves, and bear few or many flowers according to the strength of the plant. The worst mistake in growing *O. Lanceanum* is to be always pulling it about at the roots, for it dislikes disturbance more than any other species. When preparing the compost for this plant I always use a good proportion of Sphagnum Moss and only a very little peat, as the former is not so liable to sour, and when decaying may be more easily and with less damage removed. A large plant now in flower with me has not been disturbed since it was first planted—a newly-imported piece about six years ago. The growth is free, and it never fails to flower well annually. *O. Lanceanum* likes a high temperature always and ample moisture both at the roots and in the atmosphere while growing. During the autumn the air may be kept a little drier with advantage, this having the effect of well ripening up the leaves. The plants bear almost full exposure to the sun in autumn with advantage. During the winter months the roots may be kept well on the dry side, the fleshy leaves acting in some part as pseudo-bulbs, and keeping the plants going during the winter.—H.

FLOWER GARDEN.

IRIS HEXAGONA.

MR. LEY, in his interesting article of June 18, p. 519, notes that this species is not quite hardy in England. This complaint seems common among the English fanciers of the Iris. Irises often have certain vagaries, and one hesitates to diagnose cause of failure to grow or to advance trustworthy cultural directions, but I venture the guess that the failure of *I. hexagona* in the open in England is probably due to plants having been obtained from the wrong localities, for I have in the garden plants which are as hardy as any Irises. The owner of a garden is apt to think his climate the worst in the world, but in our latitude the constantly varying winter temperature, sometimes 15° F., is very trying to plants, as much so probably as in any English location. My experience is that northern forms of *I. hexagona* are as hardy as *I. sibirica*, and southern forms quite tender. This species occurs in the middle west, as far north at least as Missouri, and in the south as far east as Florida. The forms vary little except in colouring and size of flowers, but the constitution seems to be affected by the habitat. The white form spoken of by Mr. Ley is evidently a sport, as seedlings revert to blue colouring. Blue forms vary from faint blue to the rich colouring of that known as var. *La Mance*. The veinings or markings on the lighter-coloured flowers are more extended and prominent than on the darker forms. The rhizomes of *I. hexagona* are strong, vigorous, and not easily turned aside; they have here

penetrated so densely-growing a thing as the roots of *Panicum virgatum*. Aside from open root-room, they require no other care than that given German hybrids, but I would suggest that owing to their flowering habit they be not allowed to become crowded. The leafy blooming stems are shorter than the leaves and are partly prostrate at flowering time, so that unless the plants are grown thinly the flowers are partly hidden, and the plants not so effective in the border. J. N. GERAUD.

Elizabeth, New Jersey.

LILIUM SPECIOSUM IN BLOOM.

THE different varieties of *L. speciosum* flower naturally in the open ground during the latter part of August and onwards, and at one time they were considered difficult to force prematurely into bloom. Such is, however, not the case now, and those that make a speciality of flowering *L. speciosum* have plenty of blooms by the end of June. Though enormous numbers of bulbs reach this country from Japan, for early flowering those from Holland are preferred, for as a rule they can be obtained earlier, and consequently have a good start over the others, added to which the Dutch bulbs seem to lend themselves better to culture under glass. For early flowering the bulbs must be potted as soon as possible, and in doing this space should be left at the top for a good dressing later on. Though the market grower attains wonderful results in a 4½-inch pot, yet in a general way 6 inch pots are the most convenient for these Lilies, unless a large mass or clump is desired, when of course several bulbs must be put into a large pot. When potted in the autumn they may be placed in a cold frame, the object of doing so being to ward off any very heavy rains which are often experienced about that period. They should be protected from frost either by covering or removing them indoors, and in any case as the shoots make their appearance above ground the plants must be taken into a greenhouse and a good light position assigned them. This latter is very essential, even if a little more heat later on becomes necessary, for if shaded or too much crowded together the stems of this Lily quickly elongate. As the pots get full of roots occasional doses of liquid manure are of service.

As above stated, the varieties from Holland are by most growers preferred to those from Japan for very early flowering, and among other features these Dutch forms are not so liable to turn yellow and die off when growing as the Japanese occasionally do. As this disease, whatever it is, prevails extensively among imported *Lilium auratum*, it may be that in the case of *L. speciosum* it is contracted by associating with bulbs of *L. auratum*, as the two are often sent in one consignment. The varieties preferred for early flowering are *roseum* or *rubrum*—for the two names are used so indiscriminately that it is useless to separate them—and *album*, a very desirable kind. This last differs from the Japanese *Kretzeri* (which is often sold as *album*) in many well-marked particulars. The variety *Kretzeri* has, generally speaking, a yellowish coloured bulb, rather pale green leaves, with the stem and leaf-stalks of much the same colour. In the flower the segments reflex in a very regular manner. They are white, with the exception of a greenish stripe which occupies the basal half of the middle of each segment. The buds, too, are green. The *album* of the Dutch cultivators is totally distinct therefrom, the bulbs being of a deep mahogany colour, deeper, indeed, than those of any other variety, while the stem, leaf-stalks, and unopened buds are all heavily tinged with chocolate. The exterior of the flower, too, is of the same hue. In the inside the expanded blossom is of a clear soft white without the green tinge of *Kretzeri*. The only approach to colouring is that in some individuals after the flowers have been open a few days they become slightly suffused with blush. Like most other Lilies, these varieties of *L. speciosum* when grown under glass are somewhat liable to the attacks of

aphides, but nothing like to the same extent as the forms of *L. longiflorum*, notably *Harrisii*. In any case fumigation or dipping in some of the various insecticides will soon rid them of the pest. This must be done as soon as the aphides are noticed, for they increase very rapidly, and permanently injure the buds while they are still small. T.

LILIUM TESTACEUM.

THOUGH opinions may differ as to the comparative merits of the many beautiful Lilies that we have now in our gardens, this is certainly entitled to a foremost place, while it is one of the most distinct of the entire genus. It has been many times noted in THE GARDEN, but is so charming just now when in full bloom as to well merit a passing notice. We have very few hybrid Lilies in general cultivation, but this is one of them, the parents being the Madonna Lily (*L. candidum*) and the scarlet Turk's-cap (*L. chalcedonicum*), the prominent characteristics of the two being blended in the progeny. The segments of this Lily are a good deal reflexed, nearly as much as in the Turk's-cap section, while they are borne in a somewhat open head, each blossom being disposed horizontally or nearly so. The colour of the flower is a peculiar yet remarkably pleasing shade of nankeen or buff, against which the bright red anthers stand out very conspicuously. The blossoms of this Lily, which are pleasantly scented, are a little later in expanding than those of *L. candidum*, while *L. chalcedonicum* is later still. *L. testaceum* is occasionally met with under the names of *Isabellinum* and *excelsum*. This latter name is by no means an inappropriate one, for though the height varies according to situation and other particulars, yet when well established and under favourable conditions it will run up from 6 feet to 7 feet. These tall stems, though sufficiently stout to carry the large head of blossoms, are not at all stiff, swaying as they do with a gentle breeze. As a rule, the foliage is well retained till the flowering period is over. The flowers being borne in a horizontal manner are seen to better advantage on tall stems than short. The bulb is a good deal in the way of *L. candidum*, but it does not push up radical leaves in the autumn as the white Lily does. With the exception of this last it is, however, the earliest Lily to start into growth in the spring, and though so early and the young foliage so tender, it seems proof against cold and cutting winds. *L. testaceum*, which is finely grown by some of the Dutch cultivators, succeeds in a good garden soil that is well drained, and at the same time is not dried up during the summer months. It can be depended upon to flower well the first season after planting, and is very satisfactory when grown in pots. GROWER.

LILIUM BROWNI AND L. ODORUM.

It is rather surprising that such a state of confusion prevails with regard to these two distinct Lilies, for they are readily distinguished from each other by many well-marked features. In this country we, as a rule, obtain our stock of *L. Browni* from Holland, and of *L. odorum* from Japan. This latter is often sold in London auction rooms as *L. Browni*, and this is doubtless the cause of the confusion that exists, though as soon as the leaves develop the difference can be readily detected. The bulbs of *L. Browni* are quite distinct from those of any other Lily, being narrow at the base and gradually widening upwards, with a peculiarly flattened top. They are more or less tinged with reddish brown. The leaves are long, narrow, and tapering to a sharp point. They are also of a dark green tint. The stem, which is, particularly towards the lower part, tinged with purple, is at the base almost destitute of leaves for some little distance. The flowers are large, funnel-shaped, and of an unusually thick wax-like texture; inside they are of an ivory-white tint, but heavily tinged with chocolate on the exterior of the three outer segments, so that the unopened bud is entirely of a reddish brown hue. The dark brown anthers are

very conspicuous against the rest of the flower, but in showery weather the pollen is quickly washed on to the petals and mars the beauty thereof.

In *L. odorum* the base of the bulb is broad, while the centre is slightly raised, and the colour is yellowish, as in *L. longiflorum*. As soon as they appear above ground it will be seen that the shoots of *L. odorum* are green, while those of *L. Browni* are reddish brown. The leaves of *L. odorum* are short, broad, rounded at the tip, thin in texture, and of a pale green. The flowers, too, differ from those of *Browni* in being rather more shallow and with less brown on the exterior, while when first opened they have a slight creamy tint. They are also more agreeably scented, for *L. Browni* after being opened a day or two is far less pleasant than at first. *L. odorum* is sometimes known as *L. japonicum Colchesteri*. Some newer forms of this section of Lilies have flowered within the last few years at Kew, and though, perhaps, some of them may show a leaning towards one or other of the above-named species, the fact remains that *L. Browni* as grown by the Dutch and *L. odorum* from Japan are two perfectly distinct Lilies. H. P.

IRIS KEMPFERI AT WISLEY.

THE thousands of plants growing in Mr. Wilson's Wisley garden have this season produced countless numbers of blooms, which, as regards brilliancy, purity, form, and size, leave nothing to be desired. This noble Iris, which in its true form is without an equal for the summer decoration of the outdoor garden, is, like many hardy cultivated flowers, liable to be affected by the vicissitudes of our changeable climate. It is noteworthy that Japanese plants, though generally insensible to periods of severe frost, seem unable to stand without suffering the cold easterly winds which frequently prevail with us in early spring, and many of them are extremely sensitive to the action of late spring frosts. The difficulties attending the culture of this Japanese Iris in English gardens are accentuated by the fact that it demands a never-failing supply of moisture at the roots, and must at the same time have full exposure to the sun, with a free circulation of air. With its heels in a bog and its head in the full blaze of the sun *Iris Kempferi* is quite happy. Just when the plants are coming into flower, the soil should be at saturation point, and this is where failures are so apt to occur, as the month of June is frequently very dry and parching. By setting this Iris in beds of prepared soil, so that the plants may receive all necessary attention to guard them against checks, it is, of course, possible to ensure a certain amount of success; but this is not the way practised at Wisley, neither is it the way calculated to display the characteristics of this gorgeous hardy flower. The common yellow Iris of our streams and rivers loses half its beauty when transplanted from its surroundings. Deprived of the association of the grasses, Reeds, Sedges, and other waterside plants which keep it company in a natural state, its characteristic features are in a great measure lost. One may say as much of *Iris Kempferi*, which is as much a waterside plant as our own native species. However well it may be grown in the ordinary border, its beauty cannot so well be realised as when it is placed near the water and associated with things with which it harmonises. In one place this Iris fringes a piece of water which is tenanted by Cape Pondweed, the newer Water Lilies, and other water plants and waterside things. On the banks the natural vegetation is allowed to push up, only very coarse things being kept down. The hoe and the fork do not gear them. Wild grasses come up and touch the blooms, and native plants of lowly growth can ramble at will. It is a pretty picture, with trees in the background, big white, yellow, and pink Lily blooms resting on the water, giant Gunneras and other things on the other side, with a glimpse of yellow Lilies on the rising ground, and the many-hued Iris flowers fringing the bank. It is,

perhaps, as natural an arrangement as it is possible to effect by artificial means. In other places this Iris occupies in the form of large clumps the border of miniature lakes, and in all cases bearing blooms of such quality as to prove that the plants are quite at home. In a more elevated portion of the garden, and where the natural herbage has been allowed to cover the soil, a deep ditch has been made, which, running in serpentine fashion, traverses the meadow from one corner to the other. The excavated earth forms banks, on which among the native growth are established such things as Tree Lupines, Day Lilies, and *Iris sibirica*, the last coming into flower and making a display before its more gorgeous relative comes into bloom. Through the whole length of this miniature valley *Kämpfer's Iris* is blooming and looking happy, many of the plants now in flower being produced by simply sowing the seeds in the damp bottom and allowing them to come on without disturbance. On the level ground one sees irregularly distributed the blooms just topping the grass, the effect of which is very pleasing and so natural that one could almost fancy that this Iris belongs to the native flora of the locality. J. C.

Byfleet.

Polygonum sachalinense.—Several kinds of *Polygonums* are ornamental. I find it best to grow them in a somewhat sheltered spot to shield them from the late spring frost, as they begin to grow early. Recently, when at Dillington Park, I observed several big masses of the variety above named. They were at home at the edge of a shrubby border, with various-coloured *Rhododendrons* growing near them. These were in bloom, and made a good set-off to the large strong shoots of this, which were from 10 feet to 12 feet high. I saw this growing well in a sheltered spot at Longleaf some years ago.—DORSET.

Tufted Pansy Christiana.—Although this excellent tufted sort was not recognised by the floral committee at the meeting at Chiswick, it is undoubtedly deserving of a position in the front rank. It is very free-flowering. The blooms are produced on long footstalks, which enable the flowers to stand out well above the foliage, while its habit is an ideal one. The blossoms are oval in shape, of a creamy white colour, with a yellow suffusion running from the eye into the lower petal. It is also a most continuous blossoming sort.—A. II.

Lilium giganteum at Wisley.—*Lilium giganteum* has been very fine at Wisley this year. It is grown in sheltered situations among trees and evergreens, and has thrown up flower-stems nearly 10 feet high. Every leaf seems to be in perfect condition, fresh and green, untouched by snails, and not in any way affected by the weather. When this Lily can be managed in this way it is one of the finest of Nature's productions. It is of noble growth, and yet neither flowers nor foliage exhibit any signs of coarseness.—J. C. B.

Tufted Pansy White Empress.—This is indeed a handsome flower, being of large proportions and freely produced. I cannot, however, agree with a recent correspondent that this variety is one of the whitest flowers in cultivation. It may be described as a pale creamy white, with a neat yellow eye and rayless, but there are several sorts many degrees whiter than this. All the same, growers of these flowers should make a note of this variety, as, although it has a vigorous habit, yet it is tufted. The flower-stalks are rather short.—C. A. II.

Tufted Pansy Magie.—As there is a dearth of really good rose-coloured flowers among the Tufted Pansies, this variety should make a welcome addition. It is now beautiful, its numerous growths literally covered with blossoms of large size and good form. It is the best thing in this way that has been introduced for a long time, and these on the look-out for a first-class sort would be well advised to secure this novelty. The flowers open a deep rose, but as they age the colour pales off into a soft clear rose. It is the best rose-coloured flower that I know.—D.

SAXIFRAGA LONGIFOLIA AND OTHERS.

THE flowering of Saxifrages on rockwork in English gardens, which begins with *S. Burseri* and *S. sancta* in January and continues till nearly the end of summer, may be said to attain its greatest development in June, when *Saxifraga longifolia* is in flower. As an ornament this is, perhaps, the most striking of all the Saxifrages, whether we see it when lengthened out into its fine pyramid of white flowers or as a silver-edged rosette a foot or more across, waiting to flower for another season. The species is native only in the Pyrenees, where it grows in the crevices of the perpendicular rocks, sending out horizontally its beautiful cone-shaped panicle 2 feet or more in length, waving to and fro in the breeze. As

the commonest species with which it crosses in its own home being *S. Aizoon*. The finest specimens are single crowns, and, as in all the crested Saxifrages, a crown dies after it has lengthened out and flowered. Nearly all the plants of *S. longifolia* flower once and then disappear, so the stock has to be renewed from seed. Seed should of course be saved from the finest individuals, but when many species flower together, as they do in English gardens, there is always danger of taint from some inferior kind, for these Saxifrages all cross readily. Seed should be sown in pans filled with riddled limestone between the size of wheat grains and mustard seed, and mixed with one-fourth part or less of good loam. The seedlings come up very slowly, being at least two years before they are an inch across. They should not be transplanted to the rockwork till they are 3 inches across,

prejudice against those in it which are really good.
C. WOLLEY-DOD.

Notes from Baden-Baden.—*Stachys grandiflora*, although not a new plant, is seldom met with true to name; it is, moreover, a very showy handsome hardy perennial well worth having, flowers in compact spikes, pale rose. *Lilium chalcidonicum* var. *Heldreichi* is one of our showiest summer-flowering Lilies; it is the scarlet Martagon, and differs from *chalcidonicum* in its brighter colour. It is easily grown, and only wants to be left alone for several years. Of *Scabiosa amena* I have at length succeeded in raising three fine varieties, deep ultramarine, pale sky blue, and pure white. Among an importation a new *Kniphofia* has turned up, flowers yellow, changing to orange; the foliage is grass-like, narrow, and the flowers appear from April until frost comes. Another new species has

Part of rock garden in Rev. C. Wolley-Dod's garden at Edge Hall, showing tufts of *Saxifraga longifolia*. From a photograph by Miss Wolley-Dod.

one looks at them growing on the high cliffs which rise on both sides of the torrent where it is spanned by the Pont Napoleon at St. Sauveur de Luz, and where they are finer than I ever saw them elsewhere, one wonders how it is that after seeding downwards for centuries they have not all congregated at the base of the cliffs; and so they must have done if the seed were not carried upwards by violent winds. It is generally thought to be an essential of this species that it grows as a single crown, and does not, as closely allied Saxifrages do, spread laterally by offsets. I do not, however, find this one-crowned character given by botanists, nor is it invariably present. Still, when several crowns are found united, there is generally some suspicion that it is hybridised,

and then care should be taken that there is a deep crevice in which they can root firmly, and they must not be expected to maintain themselves by spreading their roots over the surface. They seldom flower till five or six years old. In the engraving the plants of *S. longifolia* are shown in a group without flowers. Those in bloom belong to *S. Hosti*, *S. lutescens*, *S. Maenabiana* and some others which flower in June, but with a spreading panicle instead of a conical head. Many neat smaller kinds flower simultaneously with these, amongst which are several varieties of *S. Aizoon*, *S. cochlearis* and *S. valdensis*. These are followed in July by some very ornamental species of *Sedum*, which are not sufficiently appreciated, perhaps because some of the genus are so weedy as to cause

white flowers—perhaps 500—in a very long spike, and is a most striking plant, which I hope to distribute this autumn. There are several new *Richardias* with white and sulphur-coloured spathes. *R. Adami* still holds a foremost rank; its half white half violet-black flowers at once attract the attention of visitors.—MAX LEICHTLIN, *Baden Baden*.

The Ononis.—Though hardly to be classed as shrubs, some of the *Ononises* should commend themselves to lovers of flowering shrubs, their general appearance being shrubby and they flower freely. Our native form, the common *Rest Harrow*, is a pretty plant when seen in broad patches by the roadside, but some of the imported forms are great improvements on it. I think *O. rotundifolia* is the best of them all, and I have in it a sub-shrub with leaves like those of a wild *Rose*

or a Sweet Brier and Pea-shaped rose-coloured flowers, borne mostly in triplets on the new growths. It is quite hardy, and grows about 2 feet high in any common garden soil, being best placed on a mound or in the rock garden. A good plant was exhibited at the recent Temple show, where it attracted considerable notice. *O. arragonensis*, a yellow-flowered species, said to be half hardy, is hardy enough to pass safely through any ordinary winter in elevated positions throughout the southern counties, and *O. natrix* is quite hardy, the flowers orange-yellow, coloured with reddish-brown stripes and veins. *O. fruticosa*, with purple flowers borne in triplets and with good foliage, is a handsome and hardy species.—J. C. T.

FLOWER GARDEN NOTES.

SOME INTERESTING CONTRASTS.—In a recent note on the association of certain flowers with hardy shrubs I referred to *Tamarix gallica* as a fine-foliaged plant that later in the season would show off brightly coloured flowers to the best advantage. For the first time that I have grown it, it is this year flowering freely, and bushy compact plants a little over 3 feet in height and as much in diameter thinly planted among crimson *Antirrhinum* help to make a very charming bed. A shady north-west corner partially planted with *Gloire des Polyantha* Rose was last autumn filled in with *Spiraea astilboides* transferred to this position from a rather dry border. Both are now in flower and the effect is very pleasing. The Roses have developed into good bushes and stand up well above the *Spiraeas*, the latter, it may be added, being well away from the bushes. Both *Gypsophila* and the Sea Lavenders make admirable companions for brightly coloured flowers, either annual or perennial, the latter for choice, as being the more natural association. I am interested in the growth of a batch of seedling *Statice*s planted in the autumn of 1896, and noted last year as varying considerably alike in shade of flower, size of panicle, and early or late development. Present appearance seems to indicate that the same variation will be apparent this season. On large lawns no more interesting feature is to be found at this season of the year than big bushes of garden Roses. I made to-day a rough measurement of an *Aimée Vibert* that was planted eight years ago against an old tree stump: it is 10 feet in height and nearly 20 feet in diameter, a mass of flower, with just sufficient foliage showing between the clusters to relieve the flat surface. On another old tree stump some 20 yards away from the *Aimée Vibert* a *Crimson Rambler* was planted last autumn; it is going away well, and in some future number of THE GARDEN I hope to chronicle the fact that it has attained the dimensions of the white *Noisette*. Similar effects on a smaller scale can be obtained on small lawns with the aid of the *Polyantha* type, of which, in addition to *Gloire des Polyantha* above mentioned, *Anna Marie de Mont-ravel*, *Mignonette*, and *Perle d'Or* are among the best. I have not tried the newer *Mosella* and *Perle des Rouges*, but should imagine that both, especially the latter, will prove very valuable additions to this interesting section. Returning again to the question of present contrasts in the flower garden, I am inclined to enforce the opinion that an equally effective and much more natural display is obtained with hardy than with tender plants, unless the latter are thoroughly well done. No one can say a word against the splendid specimens of *Fuchsias*, *Heliotropes*, *Ivy-leaved Pelargoniums*, and others as employed in some of the best of our public and private places, but if such plants are scraggy in habit and only thinly flowered they present a sorry appearance.

SOME GOOD ANNUALS.—*Gypsophila elegans* I should like to make a special note of as paniculata is very late this year, and the value of the annual is therefore considerably enhanced. Where it was sown early, and either allowed to remain after thinning in the same position or carefully transplanted, it is now in full flower and furnishing

splendid material for cutting; indeed, so much is it in request that it will be found advisable another season to plant out a batch for this purpose. Grown in pots it is a useful greenhouse plant, presenting a pretty and effective contrast to blue *Achimenes* and *Streptocarpus*, and at a local show it helped not a little, associated as a carpet with bright-coloured *Gloxinias* and *Maiden-hair Ferns*, in gaining a first prize for a group. *Godetia gloriosa* is a fine dark variety of this favourite annual, of sturdy, compact habit, the flowers being produced in great profusion and standing well. Alternate plants of this and *G. The Bride* make a charming bed. Anyone looking out for a dwarf bedding plant should make a note of *Marigold Legion of Honour*, a brilliant little thing that flourishes in almost any soil and lasts well throughout the season. A variety of *Salpiglossis* known as *superbissima* fully bears out the high character received with it. I have it in a bed with a good dwarf white *Antirrhinum*, and it is just beginning to make a brave display. *Coreopsis coronata* is a common annual so far as age and price are concerned, and might be grown more frequently. Larger in the foliage and much more compact in habit than others of the family, it grows into dense little bushes and throws its flowers well above the foliage. There is not much distinctive central colouring about the flower, but it is at once light, graceful, and pretty.

Clarcmont.

E. BURRELL.

HYBRID LILIES.

THE award of a first-class certificate recently to a hybrid Lily, *Lilium Marhan*, reminds one that very few hybrids of this extensive genus have become popular garden plants. The first place is certainly occupied by *L. testaceum*, a hybrid between *L. candidum* and *L. chalcedonicum*, but whose early history seems to be completely unknown. It is in every respect a very beautiful Lily, whose gracefully disposed blossoms are of a pleasing shade of yellowish nankeen or buff, while its robust constitution renders it a really good hardy border Lily. *Lilium Marhan*, whose parentage is recorded in the name thereof, is a hybrid between some form of the *Martagon* Lily and the Japanese *Lilium Hansonii*. It is after the manner of an older hybrid—*L. Dalhansonii*, of which a coloured plate was given in THE GARDEN, September 16, 1893. This was raised by Mr. Powell, of Southborough, Tunbridge Wells, and first flowered in July, 1890. In all respects it is about midway between its parents, the black *Martagon*, known generally as *L. dalmaticum*, and the yellow-flowered *L. Hansonii*. *L. Dalhansonii* has proved to be of good constitution, and is now generally to be met with in most collections, but, of course, it is as yet far from common. Under the name of *L. Beerensii* I noted a very pretty Lily in flower with Mr. Ware at Tottenham some three years ago. It was the result of a cross between *L. chalcedonicum* and the above-mentioned hybrid, *L. testaceum*. The foliage was more in the way of that of *L. chalcedonicum*, while the flowers, which suggested those of the other parent, were of a deep apricot colour, with prominent red anthers. I do not know whether this Lily is now in cultivation. *Lilium Parkmani*, a hybrid between *L. auratum* and *L. speciosum*, has attracted a deal of attention from time to time, but it does not seem very amenable to cultivation, and has not been put into commerce. It was raised in the United States by Mr. Parkman, and first flowered in 1869. Out of fifty plants raised from this cross only one proved to be *Parkmani*, the rest being simply *L. speciosum* (the seed-bearing parent). After a time *L. Parkmani* was sent to this country and passed into the hands of the late Mr. Anthony Waterer, who exhibited it at a meeting of the Royal Horticultural Society on August 24, 1880, when a first-class certificate was awarded it. It is a pity that this Lily has proved so difficult to cultivate. Several hybrids between *L. umbellatum*, *L. elegans*, and *L. croceum* have been seen within the last few years, while it is very probable that some

of the Lilies usually regarded as varieties of one or the other are in reality of hybrid origin.

Besides these many other hybrid Lilies have been raised, but they have never become generally cultivated, while a few imported forms have been by some regarded as natural hybrids. A prominent member of this latter class is *L. Alexandra*, which has been spoken of as a hybrid between *L. longiflorum* and *L. speciosum*, or *L. longiflorum* and *L. auratum*. T.

NOTES ON HARDY PLANTS.

Armerias.—It is a common thing to find these fail just when they should be at their best, especially the less common and brighter coloured forms of the common Thrift. A kind getting a foot high with very big and bright rosy flowers fails more or less every year. The cause for this will be found on close examination of the grass-like leaves. Just now the herbage is speckled all over with black dots, which are really a fungus, coming to maturity at a rapid rate. The Paris green remedy should be applied at once. There is no saving the plants of this choice kind known as *grandiflora* of trade lists unless the fungoid growths are killed before they ripen. So far as my experience goes, all the cephalotes and plantaginea group are practically exempt, but the *vulgaris* section, in which we have not a few both choice and showy, and including the pretty little *setacea*, are liable to take the fungus.

Helianthemum verustum.—This is, perhaps, the deepest colour of all the reds of the Sun Roses, but it is more especially to the double-flowered form that I would direct notice. For a month or more in early summer it is one of the richest and most reliable pieces of crimson you can get. These double flowers last for days and the succession is long. It is, however, big patches that must be had, either by patience for growth, or massing a number of plants together.

Veronica anomala on rockwork proves thriving and quite hardy; it belongs to the Box-leaved-like section. Its peculiar habit when not in flower strikes one as more curious than beautiful, but now, when in bloom, its peculiar habit is not only emphasised, but the pendent clusters or conglomerate spikes of milk-white flowers display themselves to good effect, and just now the bushes of 18 inches or 20 inches high are really attractive.

Primula Reedi at the present time is making rapid growth, and those who have had difficulty in establishing this rarest and loveliest of all Indian Primroses might profitably take a hint from the plant itself and set it permanently whilst leafing, as it is at the corresponding time that the strongest roots are pushed forth.

Parochetus communis.—It seems strange that this free-growing and ready-rooting creeper should remain so scarce in our gardens, though so well known and admired. It is true that severe winters kill it in the open, and so they do many other things we manage to always have in plenty. There must be some other cause, and as a matter of fact large batches of young stock go off in winter when protected in frames, and more, a similar state of things happens to young stock even in mild winters like last when older plants survived without any protection. A low temperature in winter does not alone seem to be responsible for the loss of young stock: the latter often fails where older plants keep on. After an experience of twenty years or more with this charming creeper, I have learnt that I can only pull young plants through the winter, either in open air, frame or greenhouse, when I have allowed the rooted offsets to remain long enough on the old plants to develop the bulky granules or warty knobs on the roots. When I get these I pot the offsets early enough in autumn so as to get them established. I rarely lose one. Still, I always give the younger rootlets a chance, and if they do not live, as they seldom do, they serve to confirm this theory. I supposed if I kept the youngest offsets growing all winter the granule-

beset roots could not matter, but I never found I could keep the plants growing all winter, not even in a greenhouse. I have got untimely seedlings to move all winter, but after the plants had matured and ones come into harmony with the seasons they proved consistent to their herbaceous nature. J. Wood.

Woodville, Kirkstall.

Hardy flowers in cottage gardens.—At the end of June when driving through the small town of Ilminster I noticed a small villa garden. The garden, though small, was an object-lesson of what can be done by using hardy plants. The centre bed was a little raised by using rough stones as an edging. As they were irregular, this allowed soil to be put in amongst them. On this, outside and amongst the stones, was a wide band of Campanula muralis, one mass of bloom. Inside of this was a grand lot of white Pink in the best possible condition. As a centre the double white Rocket was used. This, too, was in the finest health and only slightly staked. Anyone who knows these plants can imagine what a fine effect they produced.—DORSET.

Tufted Pansy Duchess of Teck.—To those who know the value of what is generally known as the Duchess of Fife family, this new sort should come as a welcome addition. This type of the plant has always been appreciated for its freedom of flowering, crawling and tufted growth, and the pleasing nature of the margined flowers. The variety under notice is supposed to be a sport from White Duchess, and the blooms I am sending you, you will notice, have a much narrower margin, and the colour of the margin is also much brighter. From a florist's point of view the form may be questioned, but all who have seen the blossoms say the uneven outline makes the flowers more pleasing and unique. The growth is similar to that of the parent variety and it is wonderfully free-flowering.—D. B. C.

Lifting and storing Tulips.—In many gardens Tulips of the later sections have fallen prey to a disease which prevents the proper development both above and below ground, and this is more common where they have been grown in the same ground without any lifting for some years. I find that such bulbs are prone to break into many bulblets instead of forming one good bulb and a little spawn, the consequence being a whole army of small bulbs and very few flowering ones. In this matter the different varieties vary, some, like Golden Eagle (which, by the way, the Dutch growers say should be Golden Crown, the true Golden Eagle being a self yellow, and the other edged with red), Gesneriana spathulata, make very good bulbs and not over-much spawn, while the Parrots and a few others break up badly. As the disease attacks the old bulb scales as well as the leaves, it is best to look over the bulbs a few weeks after they have been lifted and stored in a dry, airy shed, and remove all the outer scales, so that the new bulb has nothing left but a bright and clean covering; this gets rid

of a multitude of spores, and gives a chance of getting a clean start when planting time comes round. There can be no doubt that Tulips like a change of soil, though it happens occasionally that they do well for years without lifting, but they ought at least to be lifted when they show the least sign of falling off in quality, and are best if lifted early.—J. C. T.

IRIS LUPINA.

IRIS LUPINA grows here with other Cushion Irises on a raised bed of sandy soil. I place over them in winter a layer of straw as a matter of detail, I use the straw covers of wine bottles cut so as to lie flat. This, I think, keeps the soil open besides affording some slight protection. After flowering, I dry the Irises off by placing lights over them, so arranged that they are freely exposed to the

Iris lupina at Beechfield, Walton-on-Thames.

air. In a similar bed I grow Calochorti, Ixias, Brodiaeas, and Sparaxis, and find that they do remarkably well. The Calochorti especially flower profusely and increase very year. They are, I think, very charming.

NORMAN RUSHWORTH.

Beechfield, Walton-on-Thames.

Leucojum aestivum.—After I had penned the note on the above Snowflake which appeared in the issue of May 21, I noticed in Mr. Archer-Hind's garden at Coombeishare some of the same variety flowering finely close to the water, and in a position which I should say was certainly damper than the bed they now inhabit in my garden. Since then I have been told on good authority that the summer Snowflakes grew of yore at Dartington Hall, on the banks of the Dart, and flowered well close to the water, some, indeed, being literally in the river and often covered by it in flood time. It has occurred to

me, since I have seen one case and heard of two others, the one here mentioned and the other alluded to on p. 430, vol. iii., where these bulbs have flowered well in damp positions, whether I may have got hold of a flowerless or shy flowering strain, and that possibly this and not the condition of the soil may account for their failure to bloom.—S. W. F.

NOTES AND QUESTIONS.—FLOWER.

Tufted Pansy Flerizel.—This is now in excellent form. Very small pieces planted out during last March are now creeping slowly all over the flower beds, and at each of the short joints blossoms of the finest description are produced. The colour of the flowers may be described as bluish-lilac. The flowers stand up well on stiff, erect footstalks.—D. B. C.

Tufted Pansy Devonshire Cream.—Though the flowers of this variety lack the substance of those of many other sorts, yet they are so freely produced and neat that it should be largely grown. The growth is compact, although not so dwarf as one would like. The flowers are of a beautiful cream colour with a yellow eye. This sort commences to bloom very early in the season and continues right on through the summer.—D. B.

Tufted Pansy Celeste.—This variety is comparatively unknown, yet it is a distinctly pretty flower. The blossoms are only of medium size, but they are so pretty and neat, that loss in size is amply made up for. The colour may be described as bluish-lavender, paling slightly in the centre, and it also possesses a neat and effective yellow eye. The habit of growth is dwarf and compact. The blossoms also are fragrant.—B.

Tufted Pansy Blush Queen.—There appears to be a difficulty in making large plants of this variety the first season, judging by the results of the last two years. If the plants are cut back in the late summer and allowed to remain in the same position for another year the value of the variety is apparent. At the time of writing, these old plants are literally covered with medium-sized blossoms of a pale blush colour and very sweet scented. The plants are now in a most robust condition.—C.

DESTROYERS.

SPRAYING—ITS PAST, PRESENT AND FUTURE.

THE history of spraying is a most remarkable one, considered from almost any point of view. Fifteen years ago we knew scarcely anything in regard to it, but to-day the progressive fruit raiser can obtain reliable information upon almost any phase of the subject. The first remedies proposed were most unique, and seem to have been suggested by the same train of reasoning which actuated our grandmothers when they selected remedies for their ailing grandchildren, namely, that the more horrible the odour of a substance and the more fearful its taste, the more certain it was to prove efficacious. Yet occasionally, in some mixture of a half-dozen or more such substances, one would be introduced which was really effective, and in this way these early, spasmodic efforts to prevent the inroads of our insect enemies resulted in some discoveries of actual value. Tobacco was among the first substances to give satisfactory results, its use having been suggested, doubtless, by the experience of someone who had made an unsuccessful attempt to learn to smoke—and thus one substance after another was added to the list. But these accidental discoveries were made slowly, and their actions were but little understood, so that improvements in methods of application resulted

only after years of experience. And if the prevention of the attacks of insects was shrouded in darkness, what can we say to describe the state of affairs with reference to fungoid diseases, those mysterious visitations which often came so suddenly and always left ruin and consternation behind? What wonder that the poor fruit raiser felt himself under the ban of Providence and abandoned the field to his enemies? One can imagine that he announced to his fellow sufferers, with even more assurance than does the representation of this type to-day—"Fruit raising doesn't pay!"

But in time men began to study these matters scientifically, which is only another name for carefully. The structure and life of the insect were studied with a view to attacking it at its weakest point, and as a result we have our present system. Every new pest that has come into prominence has been subjected to the same careful study, and in every case, in the past, some method of treatment has been devised which has proved effective. The difficulty now is, not that we do not know what ought to be done, but that we do not do it. It is a curious study to look back over the past and to notice the career and final downfall of the different pests that have appeared, each heralded, as is the San José scale to-day, as the last straw which was to "break the camel's back," and to wipe the fruit industry from the earth. Yet each, after a longer or shorter time, has been subjugated by the use of some new remedy, or the modification of an old one, or by the increase of its natural enemies; and each one, after the reign of terror caused by its first appearance, has taken its place along with other pests, not, indeed, to be forgotten, but to be provided for as we provide for the destruction of weeds in our fields, or as we ought to provide. And I am willing to go on record as saying that, in my opinion, the San José scale will be no exception to this rule, but that a remedy will be discovered which will be effectual and yet cheap. I do not wish to be understood as trying to detract from the reputation which the San José scale has been able to make for itself, but I do wish to give a little hope to those poor mortals who think that the fruit industry of our own province is at an end because, forsooth, the San José scale has appeared in Ontario. I believe that whatever we can do to delay the time when we shall have this new pest to fight ought to be done, for the methods of fighting it are continually improving. And I believe that all plantations set within the last few years should be inspected, to make sure that the scale is not already within the province. Aside from this I believe we can only watch and wait. The universal adoption of spraying seems to be delayed principally by three classes of fruit raisers. First, there is the man who has not time to spray. And secondly, there is the man who firmly believes in spraying and often makes some attempt in that direction, but without any especial result either in the amount of spraying he really does or in the good which this little is able to accomplish.

And lastly, there is the man who thinks that "spraying doesn't do no good nohow." Of course there may be men in other countries, however, who still honestly doubt the beneficial effects of spraying; and I, for one, though I am somewhat of an enthusiast on the subject of spraying, am willing to concede that there may be times, there undoubtedly are times, when spraying does no good; times when it may even do harm. But these adverse results can almost always be explained after a careful investigation, and we will usually find that they are due

to our lack of knowledge on the subject. And if, in some cases, they cannot be explained, is that a sufficient reason for abandoning the practice altogether? For every instance in which spraying has proved a failure there are numberless cases where it has been an entire success; yet some men persist in looking for the failures and utterly ignoring the successes. It is singular how much evidence some people require to convince them of the utility of such a practice as spraying, and yet these same people will pay 75 cents apiece for Peach trees which are warranted to withstand any degree of cold because the sap in them "goes down" in winter or does not "go down" (either warrant is equally effective in securing their orders), and they will not hesitate a moment to pay 1 dol. apiece for Pear trees that are warranted to be "blight proof," though this warrant consists only in the word of a "fruit tree agent," that class of individuals which, with certain notable exceptions, has perpetrated more frauds on a long-suffering public than has any other, with the possible exception of the lightning-rod dispersers. It certainly is true that "people like to be humbugged."

But admitting, for the sake of argument, that the practice of spraying still occupies debatable ground, let us see what has been done to show that it is effective in preventing the ravages of our insect and fungoid enemies. If we look for evidence among our own neighbours I think it will not be lacking. I have talked with a number of men in this province who have told me that during last season, when so few Apples were raised, the men who did succeed in producing a fairly good crop were those who persistently sprayed their trees; and not only did they produce more fruit than their neighbours who did not spray, but it was better fruit, free from the black spot which so injures the appearance and keeping qualities of our Apples, and free from worms. If we go farther from home there is hardly an experimental station in Canada or the United States which has not experimented upon this subject and issued bulletins on the results, showing in almost every case a large increase in the percentage of sound fruit from sprayed trees as compared with that from unsprayed trees. In this connection let me quote from an article in the last number of the *Canadian Horticulturist*. Speaking of the benefits of spraying it says: "As an illustration of this, where spraying was done from 75 to 90 per cent. of the fruit was clean, while from the trees in same orchards not sprayed only 10 to 15 per cent. of the fruit was fit to pack. Spys and other red fruit from sprayed trees commanded 3 dols. 50 cents per barrel. The best fruit from unsprayed trees would bring but 2 dols. per barrel." Continuing it says: "For fear the farmer with a small orchard may think this spraying business does not concern him, one man's experience is given." Mr. George Adams, of Smithville, Ontario, writes: "I have eleven Spy trees. Eight of them were sprayed, and the result was twenty-four barrels of the finest fruit I ever picked from them. I sold them at 2 dols. 50 cents. per barrel, and four barrels of culls at 1 dol. per barrel, 64 dols. in all. These culls were not spotted, but were undersized and wormy. The three Spy trees not sprayed gave three barrels of badly spotted fruit, which sold for 2 dols. per barrel, and about ten barrels of culls which I sold for 1 dol. 25 cents for the lot." That is to say, the sprayed trees brought 8 dols. each, and the unsprayed trees less than 3 dols., a difference of more than 5 dols. per tree." Such instances might be multiplied, but it is not necessary.

EFFECT OF SPRAYING.

There are still some people who feel that substances which are so effective in destroying insects and fungi ought to have some injurious effect on the consumer of the fruit, and who, therefore, feel that they are tempting Providence every time they eat an Apple or a bunch of Grapes that has been sprayed. For the benefit of such people let me quote from the late Mr. Lodeman, of Cornell University, a recognised authority on spraying. He says: "Fears have been entertained that some substances are dangerous, even when not visible, on account of their effect upon the crop, which was supposed to be poisoned. This subject was well agitated when Paris green and London purple began to be commonly used in the destruction of the Potato beetle. My analyses were made, but no arsenic could be found either in the tubers or in the parts above ground, and soon all fears of arsenical poisoning disappeared and Potatoes treated with the arsenites were used without question. Another equally groundless objection was raised in regard to Apples which had been sprayed for the canker worm or codlin moth. It was said that the bloom found on such Apples consisted largely of the arsenic which had been applied to the trees to destroy insects, and that such Apples were unfit for use. These reports have led to many analyses of sprayed fruit, and only in rare cases has even a trace of arsenic been found. It is only when very late applications are made, such as are utterly useless, that any of the poison is found upon the fruit, and then the quantity is so minute that it could in no way cause injury to the consumer. But even though all the poison sprayed upon the Apples in making necessary treatment would remain there undisturbed, a person would be obliged to eat at one meal eight or ten barrels of fruit in order to consume enough arsenic to cause any injury. As a matter of fact, however, the poison all disappears during the growth of the Apples, and these are as wholesome as though no treatment had been given, and even more so." Similar objections have been raised against Grapes sprayed with Bordeaux mixture, and the following paragraph is a clear and concise statement of the facts bearing upon the case: An adult may use about eight grains of copper per day without fear of the results, and Grapes properly sprayed would contain not more than eight-hundredths of a grain in 4 lbs. or 5 lbs. of fruit. "On this basis an adult may eat from 300 lbs. to 500 lbs. of sprayed Grapes per day without fear of ill-effects from the copper." Equally conclusive figures have been given by the Experimental Station of Michigan to show that there is not the slightest danger from pasturing stock in orchards which have been sprayed with Paris green. I shall not give these figures, because I believe that if anything could be done to convince fruit raisers that it is bad practice to pasture their orchards, a long step in the right direction could be taken, and it is possible that fear of evil effects of Paris green may help on the cause. It is probable, however, that if this fear has any effect it will be to prevent spraying and not the pasturing of orchards. In order to understand more fully what we ought to do to make our spraying most effective, let us consider a few points in regard to the life history and structure of fungi and insects. First, with respect to

FUNGOID DISEASES.

What is it which causes the black spot of Apples, leaf blight of various trees, and other similar diseases? In each case it is simply an exceedingly small plant, very different from

our conception of what a plant is, and this little plant grows within the leaf or fruit for a certain length of time, and then produces its own fruit. These plants are produced from what is called a spore, corresponding to the seed of higher plants, and exceedingly minute, so that, in most cases, it can be seen only with the aid of a microscope. In the spring these little spores, which are very abundant, are blown about by the wind and finally lodge upon the leaf or fruit to be attacked. Here, under favourable conditions of warmth and moisture, the spore germinates, just as a seed would do in the ground, and sends out a little sprout. This sprout grows on the surface of the leaf or fruit for a time and then enters into the tissues of the plant, either through one of the minute openings, called breathing pores, which are quite abundant on the surface of many parts of plants, especially the leaves, or else it bores directly into the plant. Once inside, it branches and grows about through the tissues of the plant, just as roots grow in the ground. It takes up the juices of the host plant and appropriates them to its own use, and finally, when it has completed its growth, it bears its fruit, producing spores like that from which it started. These spores are usually dark in colour and are produced at or near the surface of the host plant. They are so abundant as to give to that particular spot a dark colour. It is these spores which give the characteristic appearance to the disease known as "black spot" of the Apple. This, in brief, is the history of a typical fungoid plant. Many of them vary in some particular, but this is sufficiently accurate to serve our purpose.

Now let us see what points we can observe which may aid us in applying our sprays so as to accomplish the most good. In the first place it is quite evident that in dealing with these pests all our applications must be preventive, and not remedial. For when once the fungoid plant gains access to the leaf or fruit, it is beyond the reach of sprays, and can be destroyed only by destroying also the part affected. We must, therefore, begin to spray early, or the enemy will get ahead of us, and gain access to the plant before we are aware of it. Secondly, we must keep the plant protected with our sprays so long as there is any danger from the attacks of the fungus. And, lastly, since the spores are so very small, we must use every precaution to see that all parts of the plant are reached by the spray, and not only upon the spore alighting upon the particular spot where we have prepared for its reception. I would suggest the following treatment for the "black spot" of the Apple, or leaf blights, which are a fair sample of this class of disease: First, spray the trees, before the buds begin to swell in the spring, with a solution of copper sulphate or bluestone, 1 lb. to 15 gallons of water. Let me emphasise the fact that this must be done before the buds swell in the least, or they may be injured by the treatment. Next, as soon as the leaves are well "out," spray with Bordeaux mixture, and continue to spray with this latter whenever an application is needed. As to the number of times to spray, that depends greatly on the weather. If there is no rain, a single application may last for two or three weeks, but with heavy rains a second application may be needed in as many hours. From two to six will usually be sufficient, according to season and variety. The labour of preparing Bordeaux mixture can be very materially lessened by the use of what is called a stock solution of the copper-sulphate. That is, instead of weighing out 6 lbs. of bluestone and dissolving it each time that you wish to

prepare a barrel of the mixture for use, instead of this, dissolve, at the beginning of the season, a quantity of the bluestone in water, say at the rate of 1 lb. of bluestone to 1 gallon of water. Then all that is necessary, when you are ready to spray, is to measure out 6 gallons of this solution, and you have 6 lbs. of copper-sulphate. The lime cannot be treated in quite the same way, but enough should be bought in the spring to last through the season, and be sure that it is fresh. Then slake the lime, and keep it in what is known as the "putty." If it can be kept under water so much the better. Of course, when wanted for use it cannot be weighed out, or measured out, and, consequently, we must test the solution to see when enough has been added. This is done as follows: Put the 6 gallons of copper-sulphate solution into the barrel, and add 10 or 15 gallons of water to make the solution more diluted. Now take some of the lime putty and mix with water as though you were preparing some whitewash. Add this to the solution in the barrel, and stir thoroughly. And now apply the test to see if enough lime has been added. Take a pen-knife with a bright blade and place the tip of the blade in the mixture, moving it backward and forward for a minute, and then examine it. If you have not added enough lime you will find bright, metallic copper deposited on the blade, and you must add a little more lime, stir well as before, and test again. After a few trials one can tell very nearly how much lime is required. By simply adding a quarter to a third of a pound of Paris green to each barrel of Bordeaux mixture, we may be able to deal with both our insect and fungoid enemies at the same time, thus reducing both cost and labour.

Use the best materials in spraying, pure Paris green, fresh lime, and copper-sulphate in crystals. They may cost you a little more, but the better results will very much more than pay the difference. But whatever else you may do that is not strictly rational, do not spend any money for patent exterminators, either of insects or fungoid diseases. Buy the materials and mix them for yourself, and then you will be sure what you are applying. Some of those patent concoctions may be all right, but too many of them are like the remedy for which the hotel-keeper's wife paid an exorbitant price, and which was warranted to clear the house of bed bugs. She received a small package of Paris green, with these instructions: "Capture the bug, squeeze the back of his neck till he sticks out his tongue, and then apply a few grains of Paris green." The importance of a fine spray cannot be over-estimated, since by its means all parts of the plant may be reached and protected from insects and fungi. Materials for sprays must be cheapened, either by the discovery of new substances, which are effectual, or by cheapening the production of those already in use, and some power must be introduced which shall be cheap and efficient, and which shall relieve the fruit grower from so much back-aching work at the end of the pump handle. Add to all this the fact that a small army of investigators will continue to study the insect and the fungoid plant from every point of view, and to suggest, year by year, new methods by which we may hope to make our attacks more and more successful. One other improvement we must hope for in the future, and that is that every fruit grower, whether he has two Gooseberry bushes or 2000 acres of orchard, shall spray his plantations thoroughly and intelligently. Then we can offer our fruit with confidence, sure that it will be satisfactory and sure that we can find a

market for all that we can produce. F. C. SEARS, in the "Annual Report of the Fruit Growers' Association of Nova Scotia."

THE PEA THIRPS.

(THRIPS PISIVORA.)

COMPLAINTS were made, according to a leaflet (No. 48) issued by the Board of Agriculture, by Pea-growers in Essex in the summer of 1896 of injury caused to Pea plants by an insect said to be a species of thrips. Some injured Pea plants and specimens of an insect found upon them were received by the Board of Agriculture early in July, 1896, and the insect sent with them proved to be the Pea weevil (*Sitona lineatus*), and not a species of thrips. Again, in July, 1897, information was received by the Board that the thrips insect was spoiling the Pea crop in parts of Essex. No specimens were received, and it was assumed that the Pea weevil was the offender; but about the same time injured Pea plants were submitted by growers of Peas in fields and gardens in Kent which were infested by a species of thrips. The haulm in these cases was fully developed, and in many instances it was luxuriant, but flowers and perfect pods were generally wanting. Here and there a plant was found having a few abortive flowers and flowers with dried-up calyces and shrivelled petals, and an occasional pod was seen without the sign of a Pea in it, distorted and prematurely browned by the punctures of the thrips. It appeared that the continuous sucking action of numbers of these insects and their larvæ had prevented the fructification of the plants, and in most cases had completely arrested the formation of flowers and pods, the insects having arrived on the scene just at the time when the flowers should have formed and the haulm was in full vigour. Where the flowers and pods should have been there was a shapeless mass of "pungled matter," which is the expressive term applied by Curtis to wheat plants similarly affected by another species of thrips, known as *Thrips cerealium*. Thus, there was the unusual spectacle of whole rows of Pea plants of over average size, good colour, and apparent health without flowers and pods and utterly useless. Upon examination by a casual observer, the insects would hardly be discovered, as they are very minute, and if noticed they might very naturally be regarded from their size as too insignificant to cause such wholesale mischief.

LIFE HISTORY.—The thrips found in these Pea plants is probably the same species of thrips as that observed and described by Westwood as infesting and injuring Pea plants in precisely the same manner as has been described above. Westwood regarded this as an unnamed species, and styled it *Thrips pisivora*, and from his figure given above and descriptions it seems to be identical with the specimens forwarded to the Board of Agriculture. In size it is hardly the twelfth of an inch in length when full grown, and in the larval state it is not quite so long. The insect is greyish yellow in colour, without wings, and possesses seven-jointed hairy antennæ, four of the upper joints being yellowish and the lower ones black. The eyes are red, and the mouth is furnished with a short fleshy sucking apparatus; there are three pairs of legs, with feet shaped like bladders, which is characteristic of some species of Thripidae; and at the end of the body there is a brown or reddish brown ovipositor. The winged specimens of the thrips found on the Pea plants were darker in colour, and had two pairs of wings with long fringes, folded down the whole length and extending beyond the body. West-

wood, in his description of the Pea thrips, evidently holds that the females of this species are wingless, as he says, "We met with no males, unless indeed a very few other black fully-winged specimens may be of that sex." In the case of some species of thrips, as *Thrips cerealia*, for instance, the males are wingless. The female places eggs of microscopic size close to the midribs of the leaves, from which the larvae come in seven or eight days, and at once begin to suck up the juices of the plant. There are many generations during the summer. The winter is passed in the perfect state in the earth, or in the bark of trees and other similar shelters.

METHODS OF PREVENTION AND REMEDIES.—After an attack of this insect, Peas should not be sown in the following year near the infested spot. In gardens where Peas are trained upon Pea sticks it would be possible to spray the plants by means of a knapsack machine; but in fields where sticks are not used and the foliage grows densely, this would be almost impracticable. The best mixtures for spraying would be 5 lbs. of soft soap and the extract of 5 lbs. or 6 lbs. of quassia chips to 100 gallons of water.

BOOKS.

THE PRUNING BOOK.*

YET another addition to "The Garden-craft" series by the indefatigable Professor Bailey, of the Cornell University, New York, and equally as welcome as its predecessors. Unless I am much mistaken, this is the first work of the kind wholly devoted to pruning, and in any case it fully deserves careful perusal by all interested in the formation of trees generally, and fruit trees in particular. The book is brimful of information, the writer taking the common-sense, practical views known to be correct, and not offering mere theories formed in some study or based on the limited experience gained in a single garden. What adds so much to the instructive character of "The Pruning Book" is the large number of woodcuts, illustrating every important point brought out, numbers of object-lessons being conveyed in a manner that appeals to the mind of the most superficial reader. The work is divided into two parts, "Fundamentals" and "Incidentals," and opens with the "Philosophy of Pruning," wherein the writer maintains that pruning, while often improperly and injudiciously done, is not of itself a devitalising or injurious practice, presenting arguments from three sources—philosophy, plant physiology, and common experience—in support of his contention. As stated at the end of this interesting chapter,

There is abundant opportunity for improvement in methods, and every plant needs a particular treatment, and perhaps some species or varieties demand little, if any, thinning; but, as a whole, pruning is indispensable to successful horticulture.

Millions of fruit trees in this country testify to the truth of both the need for pruning as well as an improvement in the methods where pruning of any kind is attempted, and a pity it is we are so very behindhand in this matter. Not till pruning, not omitting the philosophy as well as the practice of it, is taught as a subject in secondary schools will any real widespread improvement take place. It is said that all-round training is an aid rather than a hindrance to the acquisition of knowledge of which the student has the greatest need, but if this variety is indispensable, why not let it take a more serviceable and lasting form than at present? Once more I repeat they do these things better in America.

Much of the pruning that is carried out among us is done by men who may be sufficiently practi-

cal, but who yet know next to nothing of the philosophy of pruning and have never "bothered themselves" as to the why and wherefore of much that they do. This ignorance would not be so general if only plant physiology had been made a subject at public schools and at various continuation classes. It is really a fascinating as well as instructive study, and no one teaches more plainly or better than Professor Bailey in the book under notice. The life history of trees, the formation and what leads to the production of wood and fruit-buds, showing what can be done by pruning scientifically, are points fully discussed, and then we come to the general make-up of the stems. The necessity for the expansion of bark is shown, and methods of assisting Nature in the case of bark-bound trees given, the right and wrong methods of sawing off limbs shown, those left with an old dead stump ("in memory of the pruner") presenting a sorry contrast to the cleanly cut branches with the bark slowly and gradually healing over the wound. Owners of forest trees that they would preserve as long as possible, but from which large limbs must, for some reason, be removed, ought to read what is stated upon this portion of the subject, a brief extract from which I append:—

The reader has already seen in fig. 73 the monument a man erected to his memory. It is a stump which is so long that it cannot be healed over, for, as we have seen, a leafless and branchless stump has no life in itself. The only chance for this stub to be healed in is from the activities of the trunk; but the end of it is too far removed from the base of supplies to receive much benefit therefrom. Having no vital part in the life of the tree, it is side-tracked and must starve.

Above the stub is shown a cluster of toadstool fungi which gains a foothold on numerous badly-pruned decaying trees in this country as well as in the United States.

Where should the limbs have been cut? There is an enlargement, or brace, at the base of a limb, and this bulge is usually larger the longer and more horizontal the limb. It is a common notion—which the writer, much to his humiliation, once aided to promulgate that the cut should be made just above the bulge and at right angles to the direction of the limb. Thus leaves a stub as shown. The proper way, however, is to make the cut close to and perfectly even with the outline of the trunk without regard to the size of the wound, leaving no portion of the amputated or dead branch on the trunk. All parts of the wound are then in most intimate relations with the trunk which supplies the materials to be used in covering the exposed surface. The area of the wood is larger, to be sure, but this is of minor consequence, and to such large wounds it is expected that the operator will apply a dressing.

It is also worthy of note that a "heavy application of lead paint is the best all-round dressing for common pruning wounds, and this would appear to be the commonest opinion with careful orchardists."

Among other matters of a somewhat similar nature, mention is made of the best method of bracing a crotch in trees to prevent their splitting badly, as too often happens in the case of large Cedar, Mulberry, and other much valued trees. The usual practice is to support crotches and weak branches by putting bands or chains about them, these eventually throttling and ruining the branches. The correct plan is to bolt them together, passing the iron through the centre of the two limbs that are to support each other, and using large heads and nuts. If long braces are needed, then it is advisable to run short bolts through the branches, and on the inner ends to have hooks or eyes into which another rod or a chain may be secured, thus allowing for the moving of the branches by the wind. The bolts soon become buried, and no ill-effects from their presence in the wood is felt by the tree.

The remarks on "Principles of Pruning" occupy sixty pages, and the general statements, twenty in number, are an epitome in themselves. The incidentals comprised in the second half of the book commence with some specific advice as to the pruning of the tops of trees, followed by the

trimming of young plants at the roots as well as branches, and after reading this, those who have previously wondered why there should be so much difference in the condition of young tree roots as received from different sources, haphazard practices compared with those based on study and experience giving by far the most unsatisfactory roots. An idea also prevails that once the tap-roots are cleanly removed from young trees little or no further thought need be taken as to the formation of other tap-roots, but Professor Bailey asserts, and is not likely to be contradicted, that if it is the habit of a plant to develop a tap-root, it will generally do so, even after its original tap is cut, generally throwing down two or even several instead of one. In addition to the American methods of pruning Apple, Pear, Peach, Plum trees and fruit bushes generally, English practices are also given, Messrs. Cheal, Rivers, Thomson being among the authors freely quoted from and duly acknowledged. That part relating to Grape culture in the open air is equally thorough, though not of great value to us in the Old World.

W. I.

GARDEN FLORA.

PLATE 1180.

ACALYPHA SANDERIANA.

(WITH A COLOURED PLATE.*)

This is one of the most distinct and ornamental of the now very numerous new plants introduced by Messrs. F. Sander & Co., St. Albans. It was discovered growing near the sea in the Bismarck Archipelago by M. Micholitz when collecting in that region. He described it as a vigorous shrub 12 feet to 18 feet high with large leaves and long tail-like flower-spikes coloured bright red. It first flowered in the St. Albans nurseries in the autumn of 1896, when Mr. N. E. Brown, of Kew, named and described it in the *Gardener's Chronicle*, calling it a very beautiful species, quite distinct from any other species in cultivation.

Most, if not all, of the *Acalyphas* are grown for their foliage, but the charm of this novelty is in its drooping female flower-spikes, which are dense and bushy, like a squirrel's tail on a small scale, and of a beautiful bright rose-madder colour, effectively contrasting with the rich green of the leaves. M. Micholitz states that it is a sun-loving shrub of strong growth, very free-flowering, and that the beautiful flower-spikes last a long time in perfection. Under cultivation the plant has exceeded the expectations formed from the collector's description, the specimens shown by Messrs. Sander at the Ghent Quinquennial and at the Temple show this year being really wonderful, whether viewed as examples of cultural skill or as decorative plants. I have seen the plant under cultivation ever since its introduction, and from its behaviour I should call it a gardener's plant *par excellence*, as it grows freely and is practically always in flower. The tails attain a length of 21 inches and the thickness of a man's thumb, whilst in colour they are of a vivid crimson, and in consistency they resemble the plush-like fabric known as chenille.

The genus *Acalypha* is a very large one, about 220 species being known. They are all tropical or sub-tropical herbs, shrubs or trees, with small flowers in axillary or terminal racemes, and in many species the sexes are on different plants, whilst in others they are on the same plant, but in separate racemes. So far only female flowers have been produced on cultivated plants of *A. Sanderiana*. The only species

* Drawn for THE GARDEN in Messrs. Sander's nursery by H. G. Moon. Lithographed and printed by J. L. Goffart.

* "The Pruning Book." By L. H. Bailey. London: Macmillan and Co., Ltd.

known to have any horticultural value beside *A. Sanderiana* are the ornamental-leaved *A. macrophylla*, *A. Wilkesiana*, *A. obovata*, *A. Macfeeana*, and others, including the new *A. Godsefiana*. In tropical gardens these plants play as important a part as the *Aucuba* does with us. They are of the easiest cultivation, and when well grown they are most effective stove plants. They have been tried as summer bedding plants in this country without success.

The cultural requirements of the plant are, briefly stated, a tropical temperature, plenty of moisture and as much sunlight as possible, avoiding actual scorching; a rich loamy soil, liberal root space, frequent syringing overhead and weekly washing of the leaves with soapy water to keep down red spider. There are plants at Kew which have been in bloom since March and are still flowering. Although new to European gardens and totally unlike all cultivated species of *Acalypha* known here, yet this plant has, as a matter of fact, been known as a garden plant in some countries in the East for nearly a hundred years. There is an excellent coloured drawing of it in the Kew herbarium dated 1812, and named *Caturus specitorus*, which is a synonym of *Acalypha hispida*, and this is the correct name of what is here called *A. Sanderiana*. Sir Joseph Hooker says of *A. hispida* that it is only a garden plant in India, although it is included in Burmann's "*Flora Indica*" and Roxburgh's "*Flora Indica*," whilst Rumphius described and figured it under the name of *Cauda felis* (cat's-tail). It is strange that a plant which has evidently been known and cultivated in Java, India, &c., for so long should have failed to attract the notice of collectors until M. Micholitz met with it. W. W.

THE WEEK'S WORK.

OUTDOOR FRUIT.

STRAWBERRIES—POTTING FOR FORCING.—This important matter is now upon us, and although the work in other departments may be pressing, every effort should be made to get this done during the next ten days or fortnight. Concentration of forces will help to conquer a difficulty such as this when it arises. With a small number, of course the labour involved is not so great. It is when it runs into the thousands that it becomes a serious inroad upon time and material too. Commence without delay to wash up the requisite quantity of flower-pots in order to have them ready beforehand and within easy reach. Six-inch pots I still find to answer the purpose best on the whole. For very early forcing a size smaller is in some gardens preferred, but this is often dependent upon the position for forcing, the variety employed, and other means as the locality as well as in proper preparation in the previous season. This season I intend to try some plants of *La Grosse Sucrée* in a smaller size, as I have noted that this makes but a moderate leaf growth under extra early forcing, and does not in consequence dry up so readily at the roots as I should like the plants to do. So far in my case no trial has been given to pots a size beyond the orthodox 6-inch pot, but I intend to experiment in this direction for late forcing to avoid, if possible, some of the watering during the month of May. If new pots be used, by all means see that they are well soaked beforehand; it is surprising what an amount of water they will absorb if fresh from the kiln, as they often are at this season of the year. It is somewhat of an old custom to use 8-inch pots, potting three runners into each pot, but for shelf work it is not advisable from point of weight alone. When done under this method I prefer to lift the runners when well rooted in the open ground.

PREPARING THE POTS.—Let this work also be well advanced, so as to cause no delay or the employment of labour which could be turned to a better purpose. The drainage employed should also be clean and sweet, being likewise used in a liberal manner. Just merely one crock and a few odd pieces are not enough; 1½ inches of drainage is not any too much. Over the crocks I prefer to use a light sprinkling of horn shavings or similar light material of a manurial character rather than any half-inch or crushed bones, which may possibly give trouble if in a green state. A light sprinkling of soot is highly essential; it acts as a deterrent to the worms when attempting to get into the soil, and at the same time assists the plants when becoming pot-bound. Do not use soot from the stoveholes as a makeshift, by reason of the presence of sulphur, but the best that can be got from coal fires only.

THE SOIL AND ITS PREPARATION.—It is not now a convenient season for the cutting and stacking of turf by most gardeners, but I will assume that a good reserve is on hand. In my own case the soil which I intend to use was carted in about midwinter, being the top 5 inches or 6 inches of an old and tough pasture. This was stacked in layers of turves or sods, with lime rubble and old Mushroom bed manure added alternately to each layer. As the soil is now being cut down for use, it all becomes well incorporated. Fortunately, when carted in, it was on the dry side somewhat, being now in the best possible condition for use, with the grass well decomposed. It is all-important in the storing of loam for future use to see that it is not carted in when too wet or soddened with rain. I shall add a light sprinkling of soot to this soil, but nothing else of a manurial character. Some growers may, perhaps, like to use more manure, which in due course will give a luxuriant leaf-development, but this is not everything, nor, indeed, is it to be desired for early forcing. Only when using poor loam or soil of a second-rate character would I advise the free use of manures, and even then it is better to employ an artificial rather than a natural manure, which is oftentimes of too forcing a nature by reason of the presence of a higher percentage of nitrogen. As the soil is chopped up and prepared for use it will be kept covered up should any rainfall be promising. To have the soil at all clammy, as when it adheres too freely to the hands, is not at all desirable; this indicates that the moisture is in excess. I do not advise that the soil be broken up too finely. Some even of the size of hens' eggs can easily be used. If the loam be heavy or close, with a tendency to solidify too much, then add either road grit or sand. The former will answer well, and it can usually be had for the carting.

POTTING THE PLANTS should be always done as carefully as if potting Cape or New Holland plants. The instructions I give are to pot firmly and evenly, and so long as the pots are not cracked during the potting I do not mind how firmly the work is performed. Guard against burying the crown, keeping it rather a little elevated than otherwise. Allow sufficient room for watering, a trifle more in fact than for most plants, as any short supply of water in a few weeks hence will check the growth. The work of potting is done much more expeditiously and more comfortably, too, by the use of potting sticks, as it is impossible to firmly compress the soil towards the base without such assistance. As soon as potting is done, let the plants be stood in their summer quarters and watered without delay.

POSITION FOR THE PLANTS.—Until last season I stood the plants upon a border which for a part of the day was shaded and otherwise retained too much moisture about them for too long a time. I found this encouraged mildew, to which *Royal Sovereign* in particular is subject. The growth that was made was vigorous enough—possibly excessive—the plants looking very well. Last year, for this reason and by force of other circumstances, a more open and breezy position was

selected, where from early morn to night every fraction of sunshine was obtainable. More attention as regards the watering was, it was true, found to be imperative, but the growth made betokened a sturdy constitution, and the after-results when forcing was on did not belie these appearances. I much prefer to stand the plants in quarters to that of single or double lines along the garden paths. It is then easy to damp them overhead after a hot day, and is otherwise more expeditious for watering. With a good bottom of ashes (cinder), which takes up largely the water from the pots and afterwards gives it off to the benefit of the plants again, there is not much to be feared from worms. As a preventive, however, against worms, it is safer to apply a dressing of lime to the ashes in advance.

VARIETIES.—These have been alluded to, and it only remains to be added that in giving a trial to fresh kinds do not enter largely into the culture of any one kind until it has been tested, otherwise valuable room and time, too, may be expended at a loss. When sorts are being added from trade sources, see that they are well watered immediately they are received and before potting takes place.

WATERING FRUIT TREES AND CROPS.—As we are now in most parts of the country passing through a period of drought, it becomes imperative to give attention to this important item of work. It is folly to allow the trees or bushes to actually suffer to a serious extent when water is at command, as in the end it nearly always involves the expenditure of more labour and of water also. If, however, the mulching was attended to as advised, a considerable amount of time will now be saved and there will be less cause for anxiety too. When watering, do it thoroughly and well; this also will be a saving in the end. I find that the serpentine spreaders now obtainable are a great saving of labour when there is a good pressure of water. All that has to be done is to keep them moved as occasion may require; one pair of hands can thus do the work of two at the least and quite as effectually. Take especial note now of all trees bearing heavy crops of fruit, such for instance as young Apple trees in the open, Pear trees on the walls (in the open the fruit is none too plentiful), and bush fruits also. Peaches and Nectarines will now be greatly benefited by a thoroughly good watering, and if need be apply a stimulus either in the form of liquid manure or of an artificial compound to meet the case. With this hot and dry weather there will be the possible danger of red spider becoming troublesome, and it will receive encouragement if there be drought at the roots. Do not now water Apricots too freely where there is any disposition to splitting; in some soils and localities this will occur, and watering now will tend to foster it. HOKRS.

KITCHEN GARDEN.

ROUTINE WORK.—The hoe should now be used freely among all growing crops. The haulm of all crops, such as Peas and Beans, as soon as gathered should be removed, and in the case of plants needed for seed only the portion required should be retained. Of late the weather has been dry, and seed beds or plants pricked out will need liberal supplies of moisture. Much better results will follow giving the moisture late in the day, and liberally instead of just watering the surface. Newly-planted Celery will require a liberal quantity of moisture; indeed, from this date the plants should never be dry at the roots. Any plants infested with the grub should be dusted over with soot after watering, or in very bad cases the leaves gone over and the portion affected removed. Marrows will now take liberal quantities of food in the way of liquid manure, and runner Beans that are podding will need water. Food also will be well repaid, and in light soils a mulch of litter or spent manure along the rows will be beneficial. Planting of all green crops should proceed apace; indeed, at this late period it will not do to wait for rain. Moisture must be given freely after planting.

ONIONS.—The spring-sown plants are much later than usual, so that feeding may yet take place. In a light soil I find soot and fish manure excellent, and given this there is no trouble with grub or disease. The food should be of a quick acting nature, and though it may be necessary in dry weather to give moisture to wash the food down to the roots the food is not lost, as the land will be in good condition for future crops, such as Cabbage or others that need a hard surface to create a sturdy growth. If desired nitrate of soda may be given, and I would advise two or three dressings at intervals of a week and if possible in showery weather. I use this at the rate of 2 ewt. to the acre. On the other hand few manures are better than liquid manure from cow-sheds for growing crops at the stage named, and these may be used freely. Autumn-sown Onions are now approaching maturity, and I never remember to have seen better bulbs. These will now be benefited by having their necks bent down when fully grown to assist ripening; the white varieties are the earliest to mature. These when ripe should have as cool a store as possible. The small silver varieties used for pickling should be dried and kept free of damp, another sowing may yet be made if these small kinds are liked for special uses. Land for the autumn crop should now be got ready. An open, well-cultivated quarter is best.

CUCUMBERS.—Preparations will soon be needed for an autumn supply. I find it much best to have two lots, one for the autumn and the other to provide the winter supply. In many gardens winter Cucumbers are not grown. They are by no means profitable, but the same cannot be said of the autumn supply, which I have grown in heated frames well into December. A house is best, as in wet, unless autumn mildew is troublesome. For use at the season named I have grown Tender and True and Sion House. One of the best new kinds is Rochford's Market Favourite, but this is not so good for winter as the kinds noted. Many growers retain the summer fruiter for autumn supplies. I do not advise it, as much better results are secured from young plants, new soil, and a clean house or pit. Plants raised now should not be fruited too freely at first. Much better secure an ample top growth and plenty of roots before taking much fruit. Treated thus there will be no difficulty in having a good supply from October to Christmas. Much the same remarks are applicable to plants grown for fruiting from December to March. I do not allow the plants to bear much till November, but lay in plenty of wood, as little is made in mid-winter. It is well to sow early in August for winter fruiting.

CUCUMBERS IN FRAMES.—Plants in frames that have been fruiting from May or earlier will now be exhausted. It will well repay the cultivator to plant at this season for an autumn crop. Frames are often empty now, and may be devoted to Cucumbers, and if heated there will be a good return. Market Favourite is an excellent frame Cucumber. Grown in frames the fruits are not always of the best shape, but for cooking it matters little, and the Cucumber is a charming addition to our autumn vegetables and grown at small cost. Under frame culture the most important detail will be to get a quick growth. To do this a couple of plants may occupy one light, one for the top, the other the lower part of the frame. Keep the plants close and warm, cover the glass at night and avoid draughts. A light rich soil will be best, with a liberal quantity of bone meal or old mortar rubble in the compost if the latter is heavy. I prefer early planting. I usually sow two seeds in a 3 inch pot and destroy the weaker plant. When the third leaf is showing I plant out.

TOMATOES IN SPRING.—These should now be sown for an early supply in the spring, and though many rely upon plants struck from cuttings, of late years I have obtained much better results from seedlings. Many may object to sowing in August for fruiting next March or April,

but it is impossible in most parts of the country to set fruits in midwinter; it thus behoves us to have plants of a fruiting size to flower at a season they will set. I find by sowing now or early in August in a cold frame, growing on as hard as possible till the end of October, the plants will early in the year grow freely and set a fair crop. With longer days the plants attain strength. I winter in low pits or shelves from October to early in the new year, when they are placed in their growing quarters, given more warmth, repotted, and grown on for fruiting. Sown now the plants may be wintered in 6-inch pots, and are fruited in 9-inch or 10-inch pots. I prefer pots to planting out, as the plants make too much leafage and the fruits do not set freely. I have plunged the 6-inch pots in soil well over the rims and got good results. There is a great gain in sowing now over sowing in November or December, as the plant, being grown as hard as possible, is sturdy and soon flowers freely. It is advisable to grow a free setter, such as Conference, Prelude, or a good form of the Old Red. Conqueror is also a good winter fruiter, but not a shapely fruit.

ENDIVE.—I briefly touched upon the value of this vegetable a few weeks ago, and I would now advise a full sowing for winter supplies. Few green crops are more useful. For winter supplies the best variety is the Improved Round Leaved Batavian. This is a very hardy variety, and when the Endive is used as a vegetable this is the best variety. The Green Curled is less hardy, but is a desirable variety for autumn supplies and salads, and where the plants can be given frame protection this variety should be largely grown. The Moss and White Curled are beautiful summer varieties, but not so suitable for autumn sowing. No matter what variety is grown, it is necessary to give good culture. I sow in land well manured, and keep the surface moist till the seedlings show through the soil. Thin sowing is a necessity, as the plants are best when lifted with a ball of earth, before they get large. If early autumn supplies are needed it is well to sow on a warm border and not transplant, merely thinning out. The thinnings will make a succession to the plants left for the earlier supplies.

MUSHROOMS.—The crop during the past three months has been obtained from beds in the open air, and so far the supply has never failed, but preparations must now be made for beds under cover. I would strongly advise those who may contemplate making a Mushroom house to avoid the old but much-followed plan of having a house at the back of glass houses heated, and with shelves or tiers one above another. Far better results are obtained in a cellar or underground structure with beds on the floor. Here Mushrooms may be grown all the year round, which is impossible in a heated dry house in the summer months. What is needed for the Mushroom is not so much heat as an equable temperature. During the past few months I have had the supply from beds under a north wall and covered with litter. Manure may now be prepared for an early autumn supply, but it requires much less drying at this time of year than in the winter months. I find it a good plan to make a bed for late summer supplies in a shed facing north, as the cooler the better, provided the rainfall can be kept clear of the beds. The Mushroom house should be thoroughly eleaned before placing new beds in the same, as woodlice and mice are most destructive. Many spawn the beds at a lower temperature than is necessary. If the heat is falling I never hesitate to spawn between 90° and 100°, and do not let the beds get too low before soiling. Another point is to secure good spawn. The cheapest is not always the best, and the best is not costly. New spawn should now be secured for this season's work, as it will run more freely and less will be needed. From now to the spring, if beds are made every month or six weeks, there will be no break in the supply. Old beds that have borne and are at all exhausted will give another crop if watered with warm water or liquid manure.

S. M.

KITCHEN GARDEN.

ENEMIES OF THE ONION.

In some localities Onions are troublesome things to grow, and it may be said without exaggeration that in places where they are liable to the attacks of fly they cause more anxiety than any other outdoor crop. Those who are troubled in this way should note what was said in a recent issue respecting the destruction of the perfect insect before it has had time to lay its eggs. It seems to me that if this practice were continued over a period of years the fly would be so lessened in numbers that its attacks would cease to cause much anxiety. Soot is no doubt a good deterrent if used at the right time and in sufficient quantity, but one application will not in a general way be enough to secure immunity from the attacks of this pest. I once lived in a district where it was said to be impossible to grow Onions; no one living there had ever seen a crop of them grown from seed sown in spring in the ordinary way. It happened that a man came to live there who had all his life prided himself on his skill in the culture of this vegetable, and he determined to show the natives that it was as possible to grow Onions there as in other places naturally favourable. The soil was pure sand to a depth of several feet, with gravel at the bottom. When once this soil became dry in the summer it never seemed to get thoroughly moist until the advent of the autumn rains. It would, I think, be impossible to find a soil naturally more difficult to deal with than this. In a dripping summer, with plenty of manure, vegetable crops came off very well, but in a dry time they of course suffered terribly. In spite of these natural drawbacks, an excellent crop of Onions was obtained. The ground was of course heavily manured to a depth of 18 inches, the seed was sown as early as it was possible to get it in, and the surface was then rolled so hard that no impression could be made by the feet when treading on it. Every two or three days during the breeding season of the fly the plants were lightly dusted with soot, the ground eventually becoming thickly coated with it, so that when the sun shone the odour from it was perceptible at a good distance away. Later on the beds had two or three good soakings of liquid manure. Although the season was very hot and dry and just favourable to the Onion maggot, very little trace of this pest could be seen and the bulbs came to a good size, the crop being what would be considered good even on ground naturally favourable to Onions. It is probable that the frequent dustings with soot kept off the fly. A single application is not likely to be efficacious where severe attacks from fly are to be apprehended.

I never knew until this year that wireworm was to be feared in connection with Onion culture, but an instance has come under my notice which proves that under certain conditions this pest is much to be feared. One of my neighbours, who, like many others, grows his Onions on the same piece of ground year after year, this season gave them a change of soil. The result is simply disastrous, for 90 per cent. of the young plants are destroyed. There is no mistake as to the cause, for wireworm can be found all over the bed. It is a curious fact in connection with the culture of this vegetable that a change of ground often does bring on disastrous results. I have known cases where Onions, having been cultivated with great success for some years, utterly failed when given the change that is of such

benefit to garden crops generally. Some of the finest crops of Onions I ever saw were grown in a farmer's garden. The man made a practice of putting on a heavy dressing of farmyard manure at the beginning of the winter. Early in February, weather permitting, it was dug in deeply, the seed being sown as soon as the ground was in good working order. The young plants made such vigorous growth that the maggot, although it generally made its appearance, never seemed able to make much headway. The grower asserted that putting on the dung early in the winter was one of the principal elements of success, as it not only came into a sweeter, more friable condition by the time it was necessary to dig it in, but that the soil, through the rain washing down the nutritive particles into it, became thoroughly enriched to the depth of some 18 inches. As soon as the roots began to travel they came at once into contact with nourishment in a form just calculated to suit their tender condition, the result being that they pushed away into growth at a much more rapid rate than is the case when the manure is given in a crude state. Judging from results, one would say that this theory was fully justified, for every year thinning was absolutely necessary. For some reason it was decided to give a change of ground, and the result was startling. The same culture was pursued, but the young plants never went away freely; the grub got among them, and the crop was a total failure. The following season the seed was sown in the old place, with the usual satisfactory results. The moral would seem to be that, having once found a position in the garden where this uncertain crop will succeed, the prudent way is to always grow it there. It would seem even in gardens of moderate extent there may be just one spot, and one only, where Onions will succeed. Why this should be and why Onions should thrive so well year after year in the same place is one of those things that has never yet been explained.

In several gardens in this neighbourhood a disease has lately appeared which is new to me. I say a disease because the roots die away up to the base of the bulb, and although with the lens I can discover no living organism, I think that this kind of dry rot must be caused by some minute fungus, which an ordinary lens is not powerful enough to discover. In any case it is not a desirable addition to the list of the enemies of the Onion, and should it become common will be a formidable foe to contend with. It is not indifferent culture that brings it on, for wherever I have seen it the ground has been well worked and manured.

Byfleet.

J. CORNHILL.

New Pea Thomas Laxton.—This is not unlike Gradus, but a larger Pea, and in quality not far behind Ne Plus Ultra. With me this year it was ready with Gradus and earlier than some of the second early kinds. I am pleased with its cropping and good qualities, and feel sure it will only need a trial to become a favourite. I note it was one of three at the Royal Horticultural Society's Chiswick Gardens that received an award last week out of a good number. Here it was not so prolific as I have seen it, but there can be no doubt as to its quality. I wish it was a little dwarfier. It is a 5-foot variety. I prefer a Pea 3 feet high for earliest work. It is an easy matter to top the haulm. The newer variety will make a splendid forcing Pea, as the plant pods to the soil, many of the pods being produced in pairs.—G. WYTHES.

—This new Pea, which was recently referred to by Mr. Wythes, promises to be a grand addition to the second earlies, indeed it has with me immediately followed the earliest-sown

Springtide and Chelsea Gem, and is a week or more earlier than Dr. Maclean, sown at the same time. From its parentage, which is said to be Gradus x Earliest of All, earliness is inherited, but the Pea partakes more of the nature of Gradus than of its other parent, the pods and Peas being large, the latter of a deep green colour and averaging eight to the pod. The haulm is robust, and with me has run to a height of 6 feet, but this no doubt is partly due to the dripping season we are getting, and which has helped Peas generally on light soils. The pods are borne singly or in pairs for the greater part of the length of the haulm, and there is every sign of its being a continuous bearer, a great merit in a Marrowfat Pea of the larger type, among which so many have only a short season. In quality and colour it is first-class, being very sweet. The stock as sent to me is well selected, and appears to be quite true to character. One hopes that this will be retained, and that the falling off which was noticeable with Gradus a year or two after it was sent out will not be repeated.—J. C. TALLACK.

Spinach as a catch crop.—In gardens where the soil is light it is a very good plan to sow any ground which falls vacant through clearing of early crops, and which is not wanted for other things, with Spinach, odd rows of which come in useful as long as they can be allowed to remain to provide supplies, which obviates the necessity of beginning on the winter Spinach proper until it has got strong. Such catch crops do good in more ways than one. The slight preparation the surface requires kills off multitudes of seedling weeds, and the Spinach itself keeps down later weed growth, while it tends also to neatness, as nothing looks worse about a garden than to see rows of spent Peas and other things standing about the ground accompanied by the attendant weeds, which have escaped the hoe in a busy time. When no longer wanted, or when the annual digging requires to be done, the Spinach can be turned in green, and is of great benefit to the soil. In closely-cropped gardens there is seldom any opportunity for letting ground lie fallow during any part of the growing season, but it sometimes happens that a plot has to lie idle for a time or be occupied with a catch crop such as I advise, and of the two the latter is preferable. Spinach seed is cheap, and it takes but little to sow quite a large plot. Probably on heavier soil the crop taken would hardly repay for the trouble of preparing the surface, and no benefit would accrue from digging in a green crop later, but where it partakes of the nature of a sand-heap, as it does here, its value is undoubted.—J. C. T.

SUMMER LETTUCES.

THE season in many respects has been a troublesome one for Lettuces, both spring and summer. In my case the greatest inconvenience was caused by the slugs. Frequent sowings were made in the ordinary course to meet the demands, which are continuous, but in many instances they had to be repeated on the same ground without even then getting a sufficient crop. But for the frequent sowings made the supply would have fallen very short of that needed. Lime and soot, dry wood ashes and burnt refuse were applied often without much effect, so far as concerned the number of slugs and their destructive work. I cannot remember another season when there were such numbers to be dealt with and their destruction so difficult to accomplish. For the early summer cutting Commodore Nutt and Early Paris Market were most useful. The latter is a fine Lettuce, both in size, appearance and quality, but, unfortunately, in hot spells of summer weather it soon runs to seed. Commodore Nutt, though small, is a most reliable little Lettuce and one I always sow for the early supply in frames. Cos varieties for a first crop in summer come from the autumn sowings, and the winter being mild, both the Bath Brown Cos and Hicks' Hardy White developed into very fine and well-blanced heads. The latter is self-fold-

ing. A very good sort, suited to the requirements of a large household or market snugly, is Sutton's Giant Cabbage. In good soil this develops a wonderful head and quite justifies its name. When matured, too, there is no loss of quality, such as sometimes comes from coarse vegetables. To get the heads full sized, the plants need plenty of room. Perfect Gem still maintains its reputation. So good was this considered last year, that I was requested to grow more of it this summer. It has a depth of colour quite its own. In the curled kinds, which are favourites with some, the old Neapolitan has a rival in New York, although the original still claims notice. These, beside being attractive in appearance, are good eating, and, unlike some of the smooth leaved sorts, remain a long time before running to seed, which in summer is such a trouble when the weather continues dry even for a short time. In soils of a dry nature these curled sorts should be more extensively grown. They would appear, however, to need a longer time to become fully developed than the smoother and compact-growing kinds. All the Year Round is too well known to need any special notice. Like the preceding, it will stand a good deal of summer weather before running to seed. Stanstead Park is useful for the autumn.

In summer Cos, Carter's Mammoth is, as its name implies, a large, and it may be said, an excellent Lettuce, and it is self-folding. Superb Cos, selected by all seedsmen as the mainstay of the summer supply, deserves particular mention. Any list would be incomplete without it. It is needless, however, to individualise, because all are so uniformly good. The White and Green Paris Cos are grown largely by some, the latter is particularly good for sowing in summer for autumn use, when there is sometimes a difficulty with others. It has a strong constitution and grows freely when some others make but little headway.

A long list of varieties is not needed by those having only a small supply to meet. There is an advantage, too, when a kind is proved in any particular garden and found satisfactory, in standing by it. It is only under trial that the merits or demerits can be known, and apart from the educational point raised by trials, there is an interest in noting the development and the time the kinds remain fit for use, once they have arrived at a matured stage. For a small garden three or four sorts selected from the Cabbage or Cos sections, whichever finds the greater favour by those for whom they may be required, would be ample for all seasons.

For sowing now there is an advantage in having firm soil: in this there is a greater reserve of moisture for the tiny plants to utilise, but a watering of the drills or beds in the evening of warm days ensures a greater success in seed germination, and a steady progress in the plants. Where there is not the time for this, mulching the drills, after they are sown and watered, will conserve the moisture for a few days, further additions to be made as often as there is the material and the need for doing it. Transplanting is not worth the time and trouble it takes to do at this time of year. Blanks occur sometimes in seed beds simply from the absence of moisture in and about the surface soil, which is often proved after rain showers. Artificial watering will bring about the same results if followed up daily and some means taken to lessen evaporation. Slugs must not be forgotten even in dry weather.

Road Ashton.

W. S.

Pea May Queen for autumn sowing.—Those who need an autumn supply of Peas will do well to make a sowing in July, and unless some care is taken in selection of variety the best results are not always obtained. May Queen is one of the best kinds for the purpose on account of its rapid growth, freedom from mildew, and fine marrow flavour. Though not a true marrow it is so good that no fault will be found as regards its quality. One advantage this variety possesses is its dwarf habit. May Queen will only need 2-feet

sticks and may be sown in rows 3 feet apart, and to gain time I find it well to soak the seed a short time before sowing.—S. M.

Potato Famous.—With me Famous is a failure, but this may be owing to the soil. Other kinds adjoining, such as Ringleader, Veitch's Ashleaf, and some American varieties are cropping well. I grew it last year and it was not so good as others—indeed, the crop was poor. I determined to give it another trial, and again the crop failed, so that this variety will not be grown again. I am pleased to note that it does well with "A. W." I liked this variety when it was first sent out. My best Potato this year—far before Victor as regards crop and earliness also—is Ninety-fold. I would ask "A. W." to give this a trial, and in addition to crop, the quality is good. I intend next season to plant this in quantity. Those who have a large family to supply will find it invaluable.—WEST MIDDLESEX.

Late Broccoli June Monarch.—In my note at p. 510 I did not refer to the varieties "Dorset" (p. 16) asks my opinion of concerning their lateness. This year I did not grow the two kinds he names, Latest of All and Methven's June. The latter I have grown in previous years and know to be an excellent Broccoli, but unless grown side by side it is impossible to give reliable data as to lateness. I referred to Medel and Late Queen, two splendid types of late Broccoli. Both these this year were earlier than usual and I had none left for early June supply; indeed, in a light soil very few after the third week in May. I think the two kinds named, both as regards quality and lateness, the best for general culture. The popularity of Late Queen and Medel will show they are appreciated, and June Monarch, being later, will be useful.—G. W.

Tomatoes outside.—The prospects for a good crop of Tomatoes on outside walls are fast disappearing, as we are now approaching the middle of July, and scarcely any fruit has commenced to swell away. The plants are healthy enough and look well, but cold nights and dull days have prevented development, and the most that one can now do will be to pinch out the leading shoots of plants earlier than usual this year and try to ripen up what few fruits may have set by the end of the first week in August. Summers like the present are disheartening to those with insufficient glass accommodation for a full supply of Tomatoes. We have here on many occasions during June and the early half of July had a minimum temperature of from 36° to 40° Fahr., and once or twice been within a degree of frost. The bigger varieties of Tomatoes will have a bad time, but as I grow very few larger ones than Conference I shall not suffer much through choosing those that take long in swelling up.—J. C. T., *Suffolk*.

Pea Boston Unrivalled.—After hearing and reading such favourable reports anent this Pea last year, I was induced to give it a trial this season, with the result that I find such reports were in no wise exaggerated. Two rows, each about 37 yards long, were sown with seed of this variety, the one on February 17 and the other on March 2, on a piece of deeply stirred and well manured ground. The seed germinated well, the plants grew away slowly at first, but made up for lost time as soon as the weather became warmer. The produce on the earlier row was ready for gathering on July 7, that on the other quite seven days later. Boston Unrivalled is described in seed catalogues as a heavy cropper, which is perfectly correct, for the haulm is literally hung with long broad pods, which by the way are produced in pairs, and contain from nine to ten fine Peas each. When cooked I find it to be quite as good as it looks, and the flavour is delicious. It is without doubt a first-rate Pea in every sense of the term, and one worthy of cultivation in private gardens where superior quality is desired in connection with quantity.—A. W.

Sowing Cabbage seeds.—The time has again come round for sowing one of the most important of all kitchen garden crops, for next

to the Potato I think the early spring Cabbage is the crop that will always hold its own against all competitors. Opinions vary as to how long the crop should occupy the soil, but there is no difference of opinion as to the advisability of getting spring Cabbages as early and fine as possible. In this locality I find the second or third week in July the best time to sow the seed. I do not think that better crops can be produced in any walled-in garden than are grown in the open fields on the south coast. If the soil is dry at the time of sowing the seed, draw the drills and soak them well with water, then scatter the seed thinly along the drills, draw in the dry soil, and cover the surface with mats or litter until the seed germinates. Artificial watering must be kept up as long as needed. Checks to growth are undoubtedly the most fruitful source of bolting or premature running to seed. Keep the plants growing from start to finish, and very few will fail to make good heads, especially if such as Ellam's Early, Wheeler's Imperial, Nonpareil, or Rainham are grown. Such kinds as Enfield Market, that grow into double the size of these, can hardly be classed with the early spring Cabbages, but do well for succession.—J. G., *Hosport*.

Parsnips and Carrots.—Both these vegetables seem to be severely attacked with

A seedling Amaryllis.

the injured portion of the leaf and burning it. Any course that destroys the grub so far tends to prevent the infliction of further injury next year. It is fair to say that in every case of superior cultivation, deep-worked, well manured, and early thinned breadths, the attacks of grubs are least in evidence.—A. D.

STOVE AND GREENHOUSE.

SEEDLING AMARYLLISES.

NEARLY all the plants usually met with in gardens under the name of Amaryllis belong to the genus Hippeastrum, but they have been so long known and have attained their popularity as Amaryllises, that such they are in a general way likely to remain. For some years they have now been growing steadily in popular favour, and a few of our nurserymen and private gardeners, too, make quite a speciality of them. Messrs. Veitch have been identified with the culture and improvement of the Amaryllis for years, and one of the finest features of their establishment is the Amaryllis display during the early spring months. Messrs. Kelway, of Langport, too, are large raisers, their speciality being a hardier section of this beautiful class of plants than is generally grown, while at the last exhibition at Ghent Messrs. R. P. Ker and Son, of Liverpool, were first in the competitive classes, in which, however, they were, I believe, the only English exhibitors.

Of private gardens the name of Westombirt has been long identified with the culture of the Amaryllis, and Mr. Chapman has raised numerous beautiful varieties. The members of this genus are readily increased by means of seed, and large numbers are obtained in this way. This is doubtless to a certain extent owing to the fact that crossing is readily carried out and the seed does not take long to ripen, while if sown at once, thrifty little plants quickly make their appearance. Thus, there is soon a show for one's trouble, but for the flowering it is necessary to wait for years. As with the raising of other plants there is always the pleasure of anticipation, and though the seedlings may not be superior to existing varieties, yet they are all good decorative plants, none the less useful because they do not exactly conform to an ideal flower. The seed ripens about the latter part of July or in August, and if sown at once it quickly germinates, whereas if kept till the spring, the results are by no means so certain. The seed may be sown in pots or shallow pans, these latter being the more convenient. A suitable compost consists of equal parts of good yellow loam and well-decayed leaf-mould, the whole being passed through a sieve with half an inch mesh. To this must be added a fair sprinkling of rough silver sand, which should be thoroughly incorporated with the rest of the soil. The pots or pans must be well drained and filled to within half an inch or less of the rim with this compost. At one time I used to scatter the seeds on the surface of the soil and then lightly cover them with a sprinkling of the same compost, but I was advised to insert each seed edgewise into the soil, which was left fairly light to facilitate the operation. After trying it for some years, it is, I think, on the whole the better plan, particularly if the seed has been kept for some time, as an excess of moisture is in this way guarded against. By some the seed is sown pretty thickly, the seedlings being pricked off as soon as the young

maggot in various places. It is strange that Onions which were so seriously injured by maggot a few years since have done so well, and do not seem to have been attacked in any way. Carrots have not suffered appreciably for several seasons. Parsnips are rarely attacked by grubs preying upon the roots, but this year I hear many complaints of the roots being perforated as those of Carrots are. Parsnip leaves show evidence of the leaf grub in a remarkable degree. Of course, by pinching, many of these pests may be destroyed, but generally a very large brown spot is manifest on leaves ere attention is drawn to them. Dressings with soot or other nauseous compounds are then too late. The time to apply these to both Parsnips and Carrots is when the plants are quite young and ere the fly deposits its eggs. Probably there is no better means of checking the depredations of the maggot at the roots than by giving rather strong waterings of soot in solution. I have noticed that both these root vegetables seem to be worse attacked when on soil that has been manured with cow-shed and pig-stye products. Those whose Parsnips are suffering from an attack of the leaf grub and find it is too late to apply a remedy will do well so far as possible to kill the grub either by pinching it or else by picking off

plants are large enough to handle, but where room is available the better way is to place the seeds in the pans at a sufficient distance from each other to allow the young plants to develop a couple of leaves or so before it is necessary to disturb them, and then they may be potted off into thumb pots, that is to say, small pots about 2½ inches in diameter. For this potting the same kind of compost may be used as that in which the seeds have been sown. If the seed is sown as soon as ripe and placed in the stove, the young plants will be sufficiently advanced to pot them off early in the autumn, when they should be again returned to a light position in the same structure and kept in a growing state throughout the winter, for it is not necessary to rest them at that period, as is done in the case of old-established plants, and indeed it is now pretty generally agreed that the better way is not to rest them till the autumn of the second year, by which time they will be good established plants in pots 5 inches and 6 inches in diameter. They may be rested altogether in a cooler structure than that in which they have been grown previously, and if dry and in good condition, a minimum temperature of 50° will suit them well. If the plants have made satisfactory progress, the strongest may be expected to flower in about two and a half years from the sowing of the seed, but most of them will be a year later than this; in fact, those that flower early will often improve as they gain strength. By some the seedlings are planted out in a prepared bed in a house or warm pit, and where large quantities are grown, a good deal of trouble is saved by treating them in this manner, but in many places there are no facilities for this, when, of course, pot culture is the more convenient. It also possesses this advantage, that any particularly choice forms can receive special attention. When grown in a mixed collection of plants, mealy bug must be jealously guarded against, as should it effect a lodgment on the bulbs it can scarcely ever be eradicated. The beautiful race of *Amaryllis* that we now possess has resulted from the crossing and intercrossing of many distinct species and the numerous hybrids raised therefrom. H. P.

Tecoma jasminoides.—For cool houses and conservatories, corridors, and similar places this makes a free-flowering and fine climber, the pretty *Dipladenia*-like flowers, hanging in profusion, making a fine show during the summer. A plant of it in the conservatory at Livermere is very beautiful just now, the long shoots wreathed with flowers, some fully open and hundreds to follow. *T. jasminoides* is an easily grown plant, thriving in any good soil, rooting freely from cuttings of half-ripened wood, and soon growing into nice plants. It is an old introduction from Australia, the flowers white, with purple rose in the throat.

Lavatera arborea variegata.—This was recently shown in good condition at the Drill Hall, and, judging by remarks then overheard, it was by some at least regarded as a new plant. This is, however, far from being the case, as it received a first-class certificate in the South Kensington days of the Royal Horticultural Society, viz., on May 23, 1882. It was exhibited by Mr. T. Smith, Lydney Park, Gloucester, with whom, I believe, it originated, and was distributed by Mr. Bull, of Chelsea, as one of his new plants in the spring of 1883. This variegated Tree Mallow comes true from seed, but, like some other subjects that can be so increased, the young plants at first show but little signs of variegation, but as they develop it becomes very pronounced. It should not be too liberally treated, otherwise the growth becomes very coarse, and the variega-

tion is not so effective as if its vigour is partially restricted.—H. P.

Two good Ivy-leaved Pelargoniums.—Many additions have been made to this class of *Pelargoniums* within recent years, and two of the very best are *Souvenir de Charles Turner* and *Beauty of Castle Hill*, both raised by the late Mr. Robert Owen, of Maidenhead, who also obtained some other good varieties. The most generally cultivated of the two is *Souvenir de Charles Turner*, a very large flower of a rich deep pink, feathered in the upper petals with maroon. For all purposes it is a splendid variety, and is in some places grown by thousands. *Beauty of Castle Hill* is a good deal in the same way, but the flowers are of a soft rose tint. An older variety, *Mme. Crousse*, is still extensively grown for windows, balconies, and similar positions. In all of the above-mentioned the flowers are double. A good white-flowered variety is still to be desired, for none of those that I am acquainted with exactly fulfil these conditions. *Jeanne d'Arc*, white, suffused with lavender, is good, and *Merimce* (raised by M. Lemoine) is almost pure white, but feathered with dark crimson.—H. P.

THE BERMUDA BUTTERCUP.

THE Bermuda Buttercup (*Oxalis cernua*) is one of the best of greenhouse *Oxalises*, and for freedom of flowering is hardly beaten by any other plant. Those who have only seen it in the semi-starved condition in which it is too commonly met can hardly realise its possibilities when given a little generous treatment. The bulbs are so small that they are generally crowded in the pots used, and starve each other. I find that one bulb in a 4-inch or three in a 6-inch pot is quite enough, and they will pay for even more room than this, if bigger sized pots are not objected to. Unlike many other bulbous plants they may be transferred to bigger pots while in full growth, so that there is no need to over-pot in the first instance, the better way being to look out the most likely plants and pot them on in spring before many of the flower spikes are thrown up. The first potting should take place in the autumn when the bulbs are dormant, treating them for the time being in the same way as *Hyacinths* are usually treated, care being taken to bring them to the light when the first signs of growth appear, and from that time ordinary greenhouse treatment may be given, or they may be forwarded by standing the pots in a light position in a vinery or Peach house just started. The little heat thus given will make a difference of a month or so in the flowering. A sandy and porous soil with manure or leaf mould added suits the plants, and in such soil manure water may be given freely. This will help to lengthen the stems and give size to the flowers. Many-flowered umbels of soft clear yellow sweetly-scented flowers are borne on stems from 12 inches to 18 inches long, and if care is taken not to let the plants become drawn the stems are strong and self-supporting, being then very useful for cutting, as the flowers last well in water. The bulbs may be bought cheaply enough from the Dutch growers who supply most of the demand for them in this country, but home-grown bulbs are just as good when once the stock has been obtained, if they are well grown and properly ripened. As the plant is not hardy in England there is no fear of its developing into a pest, as it has done in its native place, Cape of Good Hope, and along the shores of the Mediterranean, where, since its introduction, its spread has been quite wonderful, especially in a plant which forms no seed. There is a double form the flowers of which are fully double and large, but it has not the beauty of the single one.

J. C. TALLACK.

Crassula jasminea.—This forms a freely branched, dense growing plant, and in late spring or early summer every shoot is terminated by a cluster of white *Jasmine*-like flowers. Though

white when first expanded, the flowers after a time become suffused with red. They are of a somewhat thick waxy texture and remain fresh for a long time—that is, if in a greenhouse temperature and shaded during hot sunshine. It is easily increased either by cuttings or division, and all that the plants require is ordinary greenhouse treatment. Like most members of the genus, care must be taken not to over-water the plants, especially during the winter months. A soil principally composed of loam, with some well decayed manure and sand, will suit this *Crassula* well. It is a native of the Cape of Good Hope, from whence it was introduced in 1815.—T.

A good light-flowered Pelargonium.—In the case of *Pelargoniums*, as with all other plants, flowers of a decided tint are more popular than those in which the colours are less clearly defined, and varieties with white blossoms are always admired. Messrs. Hayes, of Edmonton, have been for so many years closely identified with the culture of the decorative section of *Pelargoniums*, that one originating from that establishment, and bearing the name of a member of the family, is sure to be of considerable merit, and the variety in question is no exception to the rule. It originated, I believe, as a sport from the well-known market variety *Dorothy*, of which in its desirable habit and freedom of blooming it is a counterpart. In colour, however, it differs widely, the flowers of *Miss Alice Hayes* being of a pure white with a clearly defined blotch and feathering of bright lake on the two upper petals. The edges of the petals are prettily crisped. As some of the most beautiful among the white-flowered kinds are of rather weak constitution, this variety, owing to its vigour and ample foliage, combined with the chaste and delicate character of its blossoms, should ere long become very popular.—H. P.

Metrosideros floribunda.—This New Holland plant is far better known by the above name than that of *Callistemon Salignus*, under which head it is now, I believe, included. It is one of the finest of the *Bottle Brush* plants, a name by which several different members of the *Myrtle* order are known, owing to the fact that the flowers are crowded together for some distance quite round the shoot, and as in common with many of their allies the most conspicuous feature of the inflorescence consists in the long prominent stamens, the entire mass greatly resembling a bottle brush, which, in many instances, is brilliantly coloured. When propagated from cuttings, this species will flower freely when little more than a couple of feet high and in a pot from 6 inches to 8 inches in diameter. It is, however, as a bush from 5 feet to 6 feet high and as much through that this *Metrosideros* is seen at its very best, as it is a most brilliant object when in bloom, and a succession of these showy brushes is kept up for some time. Its cultural requirements are simple, as it will succeed perfectly in a mixture of peat, loam, and sand if given ordinary greenhouse treatment. An excess of shading is detrimental to the production of blossoms, though the display lasts longer if they are shaded when open. As simple protection from frost is all that is necessary to its well-doing, this *Metrosideros* may with advantage be placed outside during the summer.—H. P.

NOTES AND QUESTIONS.—STOVE.

Begonia Gloire de Lorraine.—This makes a charming basket plant, its shoots falling down over the sides of the basket. As the flowering shoots decay they can be removed, and others will take their place. It will go on flowering until the latter end of November.—R. D.

Hydrangea Hortensia.—There are now some fine specimens of this useful old plant at Livermere, one especially good piece carrying a large number of magnificent flower-heads. It is easy enough to grow a large plant of this species, but, as a rule, though plenty of heads are produced, they are small, but these are remarkably good in

every way. It makes a capital plant for conservatory decoration, lasting a long time in good condition.

Streptocarpus Wendlandi.—I can confirm "J. C. T.'s" remarks respecting the improved appearance of this species when the plants are massed instead of being potted singly. I was at once struck by the handsome specimens, which gain greatly by contrast with the one-sided looking things the single plants are. The long season over which these *Streptocarpi* flower is a great point in their favour, the amount of bloom produced being remarkable. "J. C. T." is singularly successful with the white forms, which in many places are not conspicuously good. The plants are always full of flowers, and the strain being especially good, they must be very useful for cutting.

ORCHARD AND FRUIT GARDEN.

APPLE THE SANDRINGHAM.

This is an excellent solid, white-fleshed, late Apple that is not too well known. It is valuable for cooking from November onward to the end of March, and its good flavour and juicy, tender flesh make it when fully ripe a very refreshing dessert Apple when juicy Apples are scarce. I find it an excellent cropper, and young trees on the Crab stock bear freely in about five years from the graft. It has an excellent habit of growth, rather inclined to upright, and fairly strong, though not gross. Grown as a garden tree on the Paradise stock it bears very large fruits, but on orchard trees it is large enough for most purposes and well above the average size of Apples. One of the handsomest of fruits as to shape, it is sometimes seen rather deficient in colour, but as grown here there is nothing to complain of in that respect, as the fruits are mostly quite high coloured, of a deep purple-red hue on the exposed parts, and green, changing to yellow, at the base and on the sheltered side. A striking characteristic of this Apple is the heavy bloom with which the fruits are covered, and they are also thickly speckled all over with tiny dots, as shown in the illustration, which gives a truthful idea of the variety. J. C. TALLACK.

LEAF-CURL IN PEACH TREES.

CAN you tell me of any cure for leaf-curl in Peach and Nectarine trees, or management by which this disease can be prevented? The trees are on a south wall in a midland county, no protection is given, soil rich loam. The disease has only given trouble of late years, but now infects both old and young trees and every kind.—K.

* * * Blister or leaf-curl on Peach and Nectarine trees is caused by a fungus known as *Exoascus deformans*, and it is very prevalent this season, points of young shoots as well as the leaves being affected—badly in some instances. Although of an infectious nature, it is powerless against trees growing under glass, even if these were moved from an open wall in the autumn after a bad attack in the spring. Nor are trees so liable to it the first season after they have been transplanted from a house to an open wall as they are in after years. Spraying with strong fungicides is sometimes recommended as a preventive, and if tried, this should be done once before the buds burst and again soon after the fruit is set, but more harm than good may result unless the greatest judgment is exercised in the matter. Cold winds are largely responsible for the mischief done, and the best protected trees are the least affected by leaf-curl. Peach walls ought to be furnished with glazed copings and an arrangement of blinds and cords, using these on cold days as well as nights to ward off cutting winds. Thus care-

fully protected there will be very few blistered leaves, and the trees pay well for the outlay and trouble taken with them. I have a number of young trees in pots for forcing. They are arranged in an exposed position in a large bed, and it is worthy of note that only the rows of trees on the north and east sides are affected by leaf-curl. All the curled leaves should be kept gathered and destroyed and the swollen ends of shoots cut away. If this is done in good time, fresh growths develop quickly and mature sufficiently to flower freely the next spring.—W. I.

Apple Irish Peach.—Those who value really first-class dessert Apples can hardly afford to be without this, though it is claimed for Lady Sudeley that it beats the older variety in every way, but I find both valuable and the piquant flavour of Irish Peach much liked. I grant that Lady Sudeley is a better grower and cropper, but the flavour, if equal, is not the same. As regards cropping, Irish Peach is satisfactory if allowed to have its head, but will bear little or no fruit when close pruned, as its habit is to bear at the extreme points of the shoots, and these must not be cut back if fruit is expected. The fruits have a tendency to cracking on some soils, and it is rare to find a tree on which all the fruits escape this defect. The flesh is tender and strongly aromatic,

Apple The Sandringham. From a photograph sent by Mr. J. C. Tallack, Livermere Park, Bury St. Edmunds.

and the fruits are never better than when gathered fresh from the tree as they ripen in August.—J. C. T.

Strawberry Sir C. Napier.—When this is grown on a soil suitable to it I consider it a most useful kind. This was brought forcibly to my notice at the end of June when looking over the Strawberry quarter in the gardens at Dillington Park, near Ilminster. The soil here is a sandy loam, just adapted to this fine old kind. The gardener, Mr. Miles, showed me several long rows of plants which he put out early last September from runners layered into pots. They had grown magnificently and had an enormous crop of fruit on them. Although several other kinds are grown (including Royal Sovereign, which is thought highly of), Sir C. Napier claimed a foremost place. Some object to this kind, being somewhat acid. Personally, I appreciate it on this account. I well remember this doing grandly at Hedsor Park, in Buckinghamshire, both in the open and in pots for forcing, some thirty years ago. I am trying it in this garden, although I am afraid it will not succeed, as the soil, I fear, is too heavy. It travels well and is much lighter

in colour than many kinds, and, being somewhat late, is good for growing on west or east borders.—DORSET.

NOTES ON APPLES.

IT is difficult to account for the haste apparent in some places to get the summer pruning done. Harm in many cases follows not only by doing it too early, but by cutting the breast wood too hard in. Looking through a medium-sized garden the last week in June, I found that all the espalier Apples had been pinched in, or rather clipped in, and many of the shoots have only about three or four leaves at the base. As the season of free growth is certainly not more than half gone, a great many of these shoots will start again, and probably the number of eyes to prune back to in winter will be very small. With such treatment as this, espalier training, which is by no means satisfactory at best, becomes perfectly useless; the trees would be better left to run entirely wild. The only parts of such trees likely to bear any fruit next season are the leading shoots where extension is going on, but in the case of trees that have filled their space the chance of a crop is indeed remote. Had the shoots, instead of being cut hard back, been pinched, it would have had the effect of strengthening and swelling up the back eyes, all resulting sub-lateral growth being pinched to the first leaf to allow free ingress of air and light. Unless attention is given to this sub-lateral growth, summer pruning had far better be left alone altogether, for, no matter how far the spray would grow by the end of the year, it would keep out less light from the back eyes and leaves than would the thicket of young shoots caused by a glut of this. The trees here were badly infested in the earlier part of the season by blight of various kinds, but the heavy rains have washed off the greater part and both fruit and trees now look clean.

As I anticipated, the very dry winter, followed by one of the heaviest crops of blossom for years, has not been followed by anything like a full crop, the Apples forming and swelling slightly in immense numbers, but the trees apparently lacking the vigour to bring them to perfection, the consequence being that they have dropped wholesale. Old and partially worn-out trees, as may be expected, are by far the worst, but in a degree the same thing is apparent in young, vigorous trees.

King of the Pippins, one of the surest croppers here, is almost bare this season, while Peasgood's Nonsuch is carrying an immense crop, and young standard and pyramid trees will have to be thinned freely. As far as possible all trees on the grass here were mulched with good farmyard manure, and this with, of course, a double object in view. So far it has not been needed as a protection from the rays of the sun, but as a manurial agent its value is apparent in the deep, healthy green of the foliage and stems, which, so far from being gross, are quite solid and brown already on their lower parts. Many of the bush and pyramid trees here have had practically no pruning since they were planted, and the stubby shoots are all in favour of this. It is necessary to so thin the growth that sun and air can reach every part of the tree, and the earlier in autumn or late summer this is done the better, as the trees then receive no check, while, should small shoots appear, these may easily be rubbed off. Even now if there are any shoots not bearing fruit that are wanted

out of the way they may be cut out, and the probability is no sign of growth will appear, as trees allowed their head and not cut about have plenty of outlet for the sap.

Hand-picking now of all fruits attacked by the Codlin moth and the removal to the garden smother of all affected fruits that have dropped will greatly lessen the numbers of this pest, and if a boy can be spared for the work the time spent is well repaid.

Ripe Strawberries by post.—Few fruits travel so badly as Strawberries, no matter how carefully packed. Many growers send forced Strawberries by post, but the fruits do not always give satisfaction. Far better send by rail, as I find fruit sent thus arrives in good condition. I recently sent some Strawberries by rail nearly 300 miles. These arrived in excellent condition, whereas some of the same variety sent 20 miles by post and packed with equal care were quite smashed. I should never have sent them thus had it not been wished. Much depends upon the packing, but much more upon the treatment the boxes receive in transit. I never send over-ripe fruit by post.—S. M.

JUNE IN SOUTH DEVON.

ALTHOUGH May was backward, the frequent showers that fell towards the end of that month and during the early days of June entitled the latter to lay claim to the appellation of "leafy June." What struck one in the leafage of the mid-summer month was its spring-like freshness, despite its abundance. The tint of May was wedded to the plenty of June. Wherever one turns the landscape discloses lovely pictures. On a swelling hill the Poppies stain with crimson a field of green wheat. Along the river banks and in the wooded glades, among the growing Braeken, in rosy regiments stand the Foxgloves' spires. The straggling hedgerows of the lanes are wreathed with festoons of Dog Roses, white, flesh colour, and shell-pink. On placid brown waters, fringed by the sword leaves of the yellow Water Flags, the yellow Water Lilies float, while from the hanging bank, where a sleepy current joins the slow tide, the gold of the Marsh Marigold shines and glitters, doubled in the dark mirror beneath a colour-symphony of brown, green, and gold. By the seashore, looking inward from the wet sands, that the ebbing waves leave with reluctant murmurs, spaces of soft colour intervene amid the grey of the pebbles, for here the Sea Pinks are blossoming in their thousands, while further inland the blue-green foliage of the yellow Horned Poppy meets the eye. The air is full of scents from meadow and garden; the perfume of the Bean fields floats afar, calling to mind the charming "Bee Song," which the honey-bees

Sang softly as they wrought,
Telling of close and garden plot
To the queen bee that knew them not;

and of the bee that had laboured in such a field
and who sang—

I thrice have filled my honey-sack
Among Bean blossoms white and black.

The hedgerows here and there are spangled with Woodrill, with its faint scent of new-mown hay, and ere the month has waned the hay itself is down and permits no rival odour to live in its "sphere of influence." The Honeysuckle, too, is blossoming profusely, and near at hand a tall Fir is garlanded 30 feet high with its perfumed mantle.

In the flower garden *Achillea ptarmica* fl.-pl. The Pearl is white with its small double rosettes, and the tall Monkshood (*Aconitum Napellus*) is blossoming by the waterside, while the light blue of *Agathaea celestis* shows itself in many a border, the plants having lived unharmed through the winter in the majority of cases. The hybrid *Aquilegias* during the early part of the month

were a lovely sight, with their delicate gradations of tint and graceful form, those bearing the long outward curving spurs being especially effective in the latter respect. A breadth of the yellow *A. chrysantha* has also been a fair sight, and I noticed a plant of the beautiful *A. Stuarti* in bloom early in June. *Allium roseum*, when massed in the rock garden, proved very decorative, and now, late in the month, the *Alstromerias* are a wondrous sight. The hybrid varieties certainly bear the palm for ornamental effect, and masses 2 yards and 3 yards in length and half as much in breadth in full flower, the blossoms ranging in hue from crimson, through rose, pink and flesh colour to cream, with a faint suspicion of orange pervading the sheet of delicate colour gradations, are the admiration of all beholders. In the south-west these beautiful plants grow rampantly, many of the flower-heads considerably exceeding a height of 3 feet, while a few of the tallest attain a stature of over 4 feet. They grow so thickly that they have to be divided every two years, and even the first year after division show unbroken sheets of blossom. *A. aurantiaca*, which even exceeds the hybrid variety in height, is not nearly so attractive in appearance, and the beautiful Lily of the Ineos (*A. pelegriana alba*) seems less easy of cultivation, as it has disappeared from my garden, though I have seen it flowering well during the past week. The elegant *Anthericum*, *St. Bruno's Lily* (*A. liliastrium*), and its larger form, which is a very distinct advance upon the type and a valuable garden plant, as well as *St. Bernard's Lily* (*A. Liliago*) have been blossoming freely, while the deep blue of *Anehusa italica* is conspicuous among the coarser growing herbaceous subjects, while in sheltered situations *A. capensis*, with its larger flowers, is very effective. The white *Antirrhinum*, many large bushes of which have survived the winter, are in fine bloom, and of the Sea Pinks, *Armeria bracteata rosea* and *A. speciosa* are bright with flower. The Cape Poodweed (*Aponogeton distachyon*) is bearing the white Hawthorn-scented blossoms on many a still pool of ornamental water, round which the *Arum Lilies* were crowded with snowy spathes throughout the month. The quaint *Astrantia maxima* has commenced to bloom, and in shady spots there is a colour still on the *Aubrietias*. At Kingswear, on the banks of the Dart, the great bushes of golden yellow *Calceolarias*, some of them 6 feet in diameter, were sheets of brilliant blossom; there, in light, shaly soil, the reverse of that usually considered requisite for *Calceolarias*, they remain unharmed winter after winter and assume giant proportions, as does *Fuchsia Riccartoni*, which, if permitted, will form trees 10 feet and more in height. Some of the *Mariposa Lilies* (*Calochortus*) have been very lovely, especially those of the *venustus* section.

Many of the *Campanulas* have been brightening the garden with their flowers. Of the border varieties, *C. glomerata*, with its purple blossoms, was at its best in the early days of the month, followed by *C. grandis* and its white variety, *C. persicifolia*, *C. p. alba* and the latter's larger form, entitled *grandiflora*, the double white Peach leaved Bellflower (*C. p. alba plena*), the purple and white forms of *C. latifolia* and *Canterbury Bells* (*C. Medium*), diverse in colour and in the shape of their flowers, while in the rock garden many dwarf varieties were blossoming, among which were *C. caespitosa*, *C. carpatia*, *C. pulla* and *C. Portensehlagiana*. In some gardens *Carnations* have come into good bloom, but in most cases the old plants look in poor health, and doubtless, to attain the best results, new plants should be raised yearly and fresh ground devoted to their culture. The blue Cornflower is in evidence on all sides, self-sown seedlings having formed large bushy plants where they have been allowed room, while *Centaurea rubra* and *C. macrocephala* are also in bloom. The railway embankments and cliff ledges are in many places bright with *Valerian* (*Centranthus ruber*) pink, white and red, the white stars of *Cerastium* have thickly covered stone edging and rockwork, while the

blue-flowered *Convolvulus mauritanicus* and the silvery-leaved *C. Cneorum*, its white blossoms suffused with a pink flush, have been very attractive during the sunny hours, and the bright gold of *Coreopsis grandiflora* is daily becoming more apparent in the border. The tall *Delphiniums* lift their stately spires of bloom on high, the single pale blue varieties being most effective in the garden. Where these plants are well grown in deep, rich soil and well looked after in the matter of watering, they produce a grand display, many of the plants throwing up fifty or more flower-heads, some of which reach a height of 8 feet, while they are so long-stemmed, that they bear neglect and drought with greater equanimity than the majority of the denizens of the herbaceous border, although under such circumstances they give but a hint of the decorative possibilities which they are capable of producing under more generous treatment. The scarlet *D. nudicaule* is a pretty flower, which, however, appears more at home in light soil in the lower situations of the rock garden than in the ordinary herbaceous border. The *Dittany* (*Dietamnus Fraxinella*) and its white variety have been in profuse bloom, and the crimson flowers of *Dianthus Napoleon III.* glow in vivid patches of colour, while a few golden stars still remain on the clumps of *Doronicum plantagineum excelsum* Harpur-Crewe, that at the commencement of June were a blaze of yellow. The velvet flowers of the *Edelweiss* (*Gnaphalium leontopodium*) are at their best in rock gardens, and the Mexican Daisy (*Erigeron mucronatus*) is covered with its simple blossoms. This plant seeds itself freely in many gardens, and in one that I lately visited hundreds of self-sown plants were blossoming along the top of an old wall and in the interstices of the stones of its perpendicular face. The long-flowering *E. speciosus*, perhaps more generally known under the title of *Stenactis speciosa*, has expanded its mauve, yellow-centred stars, and the Sea Hollies (*Eryngium*) have produced their quaint flower-heads amid the spreading braets and leaves of steely blue. Very beautiful is the metallic lustre of these in the best varieties, of which *E. amethystinum*, *E. Bourgati*, and *E. Oliverianum* are of especial merit. In the early part of the month *Erysimum Peroffskianum* gave a most brilliant display with its bright orange blossoms, a colour that even the deepest-tinted *Eschscholtzias* now in bloom scarcely rival. Naturalised in the wild garden, the white Foxgloves with their tall bloom-spikes, whose flowers the burly humble bees ceaselessly rifle, make a delightful picture, while from the broad leafage of the Plantain Lilies (*Funkia*) the flower-stems rise, strung with drooping, pale-tinted blossoms. *F. Sieboldi*, with its bold cordate foliage of glaucous green, is a remarkably handsome plant, and valuable for associating with sub-tropical subjects. The early *Gladioli* were very decorative at the commencement of the month, and in some gardens where the soil is light, *G. Colvillei* The Bride increases at a prodigious rate; indeed, as rapidly as do the *Montbretias* in the same locality. Where The Bride shows itself so vigorous, the other early kinds, such as *Blushing Bride*, *delicatissima*, *Salmon Queen*, and others, the prices of which still remain high, should be tried. The *Gaillardias* are bright in their livery of crimson and gold, and in the sunshine the orange of the *Gazanias* blazes. *Geum coccineum* is producing its bright crimson flowers, the double variety being far more lasting than the single, while the blossoms of *G. montanum* are succeeded by the feathery seed-vessels. Many of the *Geraniums* are in flower, amongst which are *G. argenteum*, *G. sanguineum*, and the delicately pencilled *G. striatum*. Of the Day Lilies, *Heemerocallis flava*, with its scented yellow blossoms, was the first to flower, followed by the stronger growing *H. fulva* with its blossoms of tawny orange. During the opening days of June, the Sun Roses in the morning hours clothed spaces of the rock gardens with a mantle of flowers, crimson and white, pink and golden, while the coral-red flower-sprays of *Heuchera sanguinea* stood in graceful company.

Hypericum Moserianum has also been blossoming, as has the common St. John's Wort (*H. calycinum*), while of the *Inulas*, *I. glandulosa* has produced its orange, narrow-rayed star flowers in number, and the coarse growing *I. Helenium* in the wild garden has followed suit. *Telekia speciosa*, a plant very similar in appearance to the last named, is also better suited to the wild garden than to the border.

June was richer than usual in the matter of Irises, the ungenial weather of April and May having retarded the flowering of the earlier sections; thus the Spanish as well as English Irises were this year both June flowerers. In heavy, damp ground both these sections disappear after a few years unless planted in a position where there is ample drainage, such as above a retaining wall of rockery. Of the Spanish Irises (*I. Niphium*), Golden King, orange, Snow Queen, white, Canary Bird, bright yellow, and Celestial, blue, are hard to beat in their respective colours, but in the English section (*I. xiphoides*) there appear to be many named varieties of equal merit in the different colours, dark blue, white and pale French grey, but of the claret-purple, Leon Tolstoi is probably the best. *Iris sibirica* has bloomed well, as have some of the German Flags, while I have seen *I. Kämpferi* flowering finely, though my own plants have been destroyed by water rats. The tall *I. orientalis*, or ochroleuca, *I. Mounieri*, and *I. aurea* are now in flower and very handsome they are. From their similarity of growth it is difficult, if not impossible, to distinguish them apart when not in flower. This year I have again seen *Jaborosa integrifolia* blooming in a warm, sheltered border. *Lavatera trimestris*, in its three colours, white, pink, and crimson, is already very ornamental, and in a shaded bed the Lilies of the Valley lasted until well into the month. In the Lily bed, *L. pyrenaicum*, usually expanding its blossoms in May, did not come into bloom until June, followed by *L. davuricum*, varieties of *L. Thunbergianum*, *L. tenuifolium*, with its light scarlet flowers, *L. Martagon* and its pretty white variety, *L. M. album*, *L. pardalinum*, and now *L. croceum*, *L. excelsum*, and the Madonna Lily. The last, I have noticed, is suffering from the disease in some gardens, but I see no signs of it in the cottage gardens, and my own plants appear quite healthy. The finest plants I have seen this year are growing in a group on a sloping bank of light soil, where they have been untouched for several years. Some of these are 6 feet in height and are flowering grandly. *L. giganteum* is not flowering with me this year, but I have seen several plants coming into bloom. Where Marliac's Water Lilies are grown they are now very beautiful, the light yellow *N. M. Chromatella* being especially lovely. Herbaceous Lupines have blossomed profusely, as have the Tree Lupines, which, when they have grown into large specimens 6 feet or 8 feet high and as much through, and are covered with their pale yellow flower-clusters, are most handsome objects, while the less common white variety is still more attractive. Unfortunately, when these plants reach a large size, as they do in a surprisingly short space of time, they usually die, sometimes, seemingly, without cause. *Libertia grandiflora* has been in profuse bloom. Where it takes kindly to the soil it makes a most effective plant. Lately I saw in Dorsetshire a great number of plants in full bloom many of which exceeded 4 feet in height. The yellow *Linum flavum* is a bright spot in the garden, while *Linum narbonne*, bearing its light blue flowers on tall slender stems, creates a pretty colour effect. In sunny, dry gardens *Lithospermum prostratum* is a mass of deep blue, while of the garden Campions, *Lychnis Viscaria splendens* fl.-pl. displays its showy flowers, and *L. vespertina alba plena* is also in bloom, but the scarlet *L. chalcidonica* had not an expanded blossom on Midsummer Day, and barely qualified to be included in the list of June flowerers. The white Musk Mallow (*Malva moschata*) is now in flower. Its name suggests a far more powerful perfume than the faint scent emitted by its flowers. Very

different in this respect is the unattractive-looking Night-scented Stock (*Mathiola bicornis*), whose fragrance when the gathering twilight has cooled the air is of delicious sweetness. It is too inconspicuous a flower to be otherwise than rare in gardens, but is well worth growing by all who love sweet odours. The *Mesembryanthemums* at Kingswear were a gorgeous spectacle at mid-summer, all the varieties tried succeeding admirably. Crimson, scarlet, rose, orange, yellow and white are all represented, the scarlet *M. amicum* being the most vivid tint. I imagined this the brightest coloured *Mesembryanthemum* in existence until not long since I saw at Abbotsbury Castle gardens one, *M. tenuifolium*, that was a shade more brilliant. In these latter gardens, as well as in those of Tresco Abbey, Isles of Scilly, a very complete collection of these plants is grown, and in each place they are very successfully cultivated. Near the water the *Mimulus* is a cloud of gold and crimson, and the brilliant effect of *M. cardinalis*, or seedlings from this variety where these are grown, is very striking. In such places the pale blue of *Myosotis palustris* charms the eye, while in shaded spots *M. dissitiflora* is not yet flowerless. The old-fashioned Bergamot (*Monarda didyma*) is bearing its crimson blossoms, and the sweet-scented Tobacco plant (*Nicotiana glauca*) perfumes the night air with its white stars, while *Love-in-a-Mist* (*Nigella*) expands its light blue flowers amid a thicket of thread-like foliage. Many of the Evening Primroses have disclosed their beauties—*E. fruticosa* with its abundant yellow blossoms, *E. Youngi*, the white-flowered *E. speciosa*, the beautiful *E. marginata*, with large, perfumed, white cups, that flourishes in the rock garden, and the giant *E. Lamarckiana*, with its towering spire of yellow blooms. The Arabian Star of Bethlehem (*Ornithogalum arabicum*) was in flower at the beginning of the month, when the Golden Drop (*Onosma tauricum*) commenced to show its yellow bells and *Oxalis floribunda rosea* was a breadth of pink in the sunlight.

The Tree Peonies were in many gardens so badly injured by the cold winds of April, that their display was not up to the standard of former years, *Reine Elizabeth* and *Lactea* being the most satisfactory, while many beautiful flowers of the herbaceous section expanded, amongst the most delightful of which was the single white *P. albiflora*. Pansies are charming now, from the old bedding varieties that dwell in the cottage borders to the many novelties of the tufted section that witch the eye with their exquisite colouring. Paris Daisies are probably more decorative than they have ever been before at this period of the year, for the large plants left in the open ground passed through the winter unharmed and are now sheets of white and yellow bloom 6 feet and more in diameter, while many of the Ivy-leaved *Pelargoniums* are in like case, and there are already hanging masses of bloom on *Mme. Crousse* and *Souvenir de Charles Turner*. The Pentstemons are also bright with flower, and the white Pinks have filled the air with fragrance, *Mrs. Sinkins*, *Her Majesty*, and *Mrs. Welsh* being improvements upon the old variety in size, even if they are not in perfume. The blue and the white *Jacob's Ladder* (*Polemonium caeruleum*) are blooming in many a cottage plot, and gardens are gay with Poppies. The vivid scarlet of the giant Oriental flames afar, the yellow Welsh nods by the side of the shady path, while the Iceland Poppies, clad in orange, white, and yellow, hold their dainty crinkled heads erect. Each day *Papaver pilosum* sheds ere noon the fragile apricot-tinted petals that shimmer in the morning sunlight, the single white Opium Poppies, that stand apart with stately mien, dream with open eyes their short hours away, and the Shirley Poppies' brave attire is soon discarded. *Potentillas* are also in bloom, the golden *P. pyrenaica* and the velvety crimson *P. nepalensis* creating a pretty contrast, while the Fair Maids of France (*Ranunculus aconitifolius* fl.-pl.) are flowering, and the old double white *Rocket*, growing vigor-

ously in large patches, breathe their sweet perfume in the evening breeze. Old plants of *Salvia coccinea* are producing bloom, and the vivid ultramarine of *S. patens* already attracts the eye, while the Caucasian Scabious has commenced to bear its large pale blue blossoms. *Sedum album* and the pink *S. arvense* are in bloom, and early in the month many of the best Saxifrages were to be seen blossoming in rock gardens, where the pretty little white-starred *Silene alpestris* was also present. Of herbaceous *Spireas*, *S. aruncus*, *S. filipendula*, *S. japonica*, and *S. palmata* came into flower ere the month had ended, while *Stocks*, *Sweet Williams*, and *Sweet Peas* blossomed in the cottage gardens. Very beautiful are some of the new varieties of the latter flower, their faint tints of mauve, sulphur, and flesh colour harmonising exquisitely when arranged together in bowls for indoor decoration. The Meadow Rues (*Thalictrum aquilegifolium* and *T. adiantifolium*) have been in bloom, but the chief charm of the latter lies in its leafage. The purple blossoms of *Tradescantia virginica* show their deep colouring here and there, while *Veronica spicata* and *V. prostrata* are still in bloom, but *Verbascum phoeniceum* was at its best during the earlier part of the month. Of climbers, the early days of June saw *Clematis montana* still in bloom, while, later on, arch and trellis were covered with the great white and mauve stars of the earliest varieties of the large flowering section. *Cobaea scandens*, which has survived the winter in the open, has produced its purple bells. *Tropaeolum speciosum*, with its roots in the shade, covers a space of rough wall with vivid scarlet. Among the

SHRUBS

large plants of *Abutilon vitifolium* were pyramids of lavender and white at the opening of the month, and *A. vexillarium* was also in bloom, as were the Ghent Azaleas with their harmonious tints. The Strawberry Tree (*Benthamia fragifera*), every spray clothed with its greenish yellow blossoms, was thrown into high relief by a background of Elms. At Kingswear *Carpenteria californica* was in flower in the open, as was an Orange tree. *Cistus* and *Ceanothus* in variety, *Cytisus Andreanus* and the yellow Broom, with tall double *Deutzias*, have been or are still blossoming, while every other plant of *Dracena australis* has produced a scented flower-spike, some of which even on comparatively small specimens have been 4 feet in length. The pink flowers of *Escallonia macrantha* have appeared somewhat later than usual this year, and the Mountain Laurel (*Kalmia*) has produced its clusters of cupped, shell-pink blossoms. The ivory-white chalice of the great standard *Magnolia grandiflora* open with increasing frequency, and *Ozothamnus thyrsoides* is smothered with minute white flowers. Here and there a specimen of *Paulownia imperialis* was to be seen in bloom, and a charming picture was presented by the flower-sprays of the white and pink *Robinias* standing out from the dark foliage of the Copper Beech. *Spiraea flagelliformis* is in bloom, and I saw lately a specimen of *Solanum crispum* in full flower. Thorns, *Veronicas*, *Viburnum plicatum*, and *Weigelas* have also been in bloom. Among the many interesting plants in flower in Mr. Archer-Hind's garden at Coombefishacre were *Bloomeria aurea*, *Borago laxiflora*, *Brodiaea stellaris*, *Caccinia glauca*, *Coronilla iberica*, *Callirhoe Papaver*, *Campanula* G. F. Wilson, and a seedling somewhat similar in appearance raised by Mr. Archer-Hind a few years ago, but the colour of which is decidedly deeper than that of G. F. Wilson, while it is of more drooping habit than that variety. At Coombefishacre this seedling goes by the name of *C. pulloides*. Of *Geraniums*, the white variety of *G. suogineum* was blossoming, as was *G. Wallichianum*, while a clump of *Cypripedium spectabile* was in fine flower, as was *Hieracium lanatum*. The white *Ostrowia magnifica*, over 5 feet in height, had expanded the first of its splendid blossoms, while among the many Lilies in flower *L. Hansoni* was conspicuous. *Lindelopha*

spectabilis, Malva Munroana, Modiola geranioides, and several Triteleias were also blossoming, while the silvery foliage of Convolvulus Cneorum was thickly strung with the coral-red blooms of Tropæolum pentaphyllum. Large bushes of the pretty little single Cluster Rose (K. polyantha simplex) were in full flower, as were many Syringas, amongst which Philadelphus speciosus, with pure white flowers over 2 inches in diameter, was most noticeable. This Syringa is quite distinct from the form generally known under the title of grandiflorus, although the two are treated as being synonymous in some dictionaries. P. Gordonianus, P. grandiflorus, P. hirsutus, P. microphyllus, and the charming P. mexicanus with its small cupped blossoms were also in flower, to be followed shortly by P. inodorus. Honeysuckle and Jasmine are bearing their fragrant flowers, and the yellow Jasminum revolutum is also in bloom. Solanum jasminoides, that commenced to flower in April, is rapidly becoming white with bloom-clusters.

June is the month of the Roses, but this year their advent was later than usual. Early in the month Réve d'Or was in the zenith of its beauty; the Austrian Briers were bright canary-yellow and glowing orange-scarlet to the tips of their shoots; on a trellis the Carmine Pillar Rose opened its richly-tinted single flowers, the Scotch Briers were masses of bloom, white, sulphur-yellow, and light pink, and the charming little Rose do Meaux produced its pink blossoms. The single white Rosa laevigata blossomed throughout the month, as did Tea Rose Socrates, one of the most fragrant Roses that blooms; then before the close of the month the Musk Roses and Cluster Roses came. W. A. Richardson is of better colour this June than it has been for the last six years. Of the Hybrid Sweet Briers Lady Penzance is very taking, and Irene Watts, one of the China section, is of a beautiful colour, something between that of Ma Capucine and l'Idéal. S. W. F.

NOTES OF THE WEEK.

Hemerocallis aurantiaca major is the finest of all the Day Lilies, a strong grower, rich in colour, an abundant as well as profuse bloomer, and, in short, the very type of what a first-class perennial should be.

Carnation Queen of the Yellows.—We send a bloom or two of our Carnation Queen of the Yellows. We may be mistaken, but think it the finest yellow yet raised.—B. S. WILLIAMS & SON.

** A handsome, richly-coloured flower.—Ed.

Strawberry Trafalgar.—By post to-night we are sending you a few fruits of Strawberry Trafalgar (new) (Waterloo x Elton Pine). In constitution and cropping qualities it is much better than Waterloo and some days later.—LAXTON BROTHERS.

** Very promising in various ways.—Ed.

Galega officinalis variety bicolor.—I send you a few blooms, knowing that you have not seen the bicolor form prior to this, as it has originated from seed at Ard-Cairn. I know the white, and the blue of gardens are well known. The bicolor form is, I think, a great beauty.—W. BAYLOR HARTLAND, Ard-Cairn, Cork.

Galega officinalis alba is a very pretty, if not, indeed, elegant, border plant, forming a perfect bush and producing throughout the summer months a most useful lot of flowers. The foliage also is neat and elegant, and supplies by its freedom of growth ample material for vase decoration without having recourse to Fern or other foliage.

Calochortus venustus albus Vesta.—This is well-nigh unique, not only for the purity of the flowers, but also for its vigour and freedom of flowering. It is, however, somewhat rare at present, though, owing to its vigour, it may be encouraged to seed, and in this way increase the stock of one of the most beautiful of the race.

Coreopsis grandiflora superba is one of the most beautiful of border plants at the present time and one well deserving of its varietal name. The tone of yellow is one of the most pleasing, and the flowers, produced in great numbers on thin and very wiry stems, are especially useful for cutting. It is,

moreover, a plant that will endure a cut-and-come-again principle.

Aplonium divaricatum.—This was one of the most distinct in Mr. May's recent group at the Drill Hall, the entire fronds being of a pale golden green tint that rendered it very striking among the many dark-leaved varieties brought together on the occasion in question. The plant has an elegant and graceful habit of growth.

Lilium candidum.—This unique garden flower appears to have been well suited this year by the continued drought that has prevailed, with the result that the snow-white heads appear abundantly in many cottage gardens, towering away to 5 feet and in some instances 6 feet high. In many wayside gardens in the districts of Feltham and Hareton this Lily is flowering freely.

Sweet Pea Butterfly is one of the most charming of these flowers, at least in the edged class. Unfortunately, there are many varieties bearing the name, and we saw quite recently as many as eight varying stocks in the seed trial grounds at Reading. A selection made by Messrs. Sutton has a lovely Picotee-like edge of blue, which is very fascinating among its fellows.

Tropæolum Fairy Queen.—This is one of the most beautiful of the trailing Nasturtiums, and specially well suited for covering a large space quickly either on the level surface or for climbing fences and the like. Fairy Queen possesses the peculiarity of having lemon-coloured flowers at first, these changing presently to a decided buff, and finally, with age, to orange, the varying shades apparent at one time on the long shoots.

Ostrowskia magnifica alba.—So much has been said, and not without some reason, in disparagement of this plant in its ordinary colour, that I am induced to send you a bloom of the white form, which is very lovely. My plant is from 5 feet to 6 feet in height, bearing six large flowers at the top, pure white, each 5 inches across, and delicately scented; in form, with the large pistil, not unlike a Hibiscus.—T. H. ARCHER-HIND, Combefishacre, Devon.

Tufted Pansy Masterpiece.—Of the many excellent white kinds of recent introduction few are equal to this variety. It is now literally covered with blossoms of good size, of almost circular form, and of the purest white, with a neat yellow rayless centre. The growth is compact, not spreading, as in many other Tufted Pansies, and growers will find in this variety a distinct gain to this class of plants, especially for massing in the hardy flower border.—D. B. C.

Tufted Pansy Virginianus.—For the last fortnight this new sort, which is said to be a cross between Florizel and Niphetos, has been flowering most profusely. The colour may be best described as a very pale bluish-lilac, somewhat like Rosea pallida in colour, but from careful observation it appears to be a distinct advance upon that variety. The flowers are of medium size and stand up on stiff, though rather short foot-stalks, and from a beautiful procumbent style of growth.—C.

Two good light-coloured Roses.—Mme. Gabriel Luizet and Mrs. J. Laing are amongst the very best light-coloured Roses, and this year they are in better form than for many years. I noticed in the reports of some of the most important Rose shows that the latter appeared in almost every winning stand. In this garden these two are amongst the most reliable kinds I grow. La France and several others are useless compared to these, although growing side by side.—DORSET.

Self-coloured Sweet Peas.—I am sending you several bunches of self-coloured kinds. From a garden point of view or for cutting these are far the best. Now there are so many really good kinds no one need grow the poor splashed and weakly-coloured forms. I recently cut some of the kinds I send you with stems each 15 inches long.—DORSET.

** A beautiful gathering, embracing all the various shades of colour now found in the Sweet Peas, from pure white to the richest carmine.—Ed.

Carnation Lord Rosebery.—Speaking generally, yellow Carnations are somewhat tender and will not bear rough usage. The one I am sending you under this name is a border or semi-border kind. Grown in pots it does well, flowers freely and does not burst its pods. It was sent to me by a friend in Ireland. From a plant in a 7-inch pot I cut from two and a half to three dozen good blooms.—J. CROOK.

** A very promising kind; flowers pale yellow, without the least sign of bursting.—Ed.

Frœbel's Water Lily.—Messrs. Frœbel, of Zurich, have sent us by post blooms of a beau-

tifully coloured Water Lily of their own raising, which we hope to flower ourselves this year. Lilies travel such a very long distance so badly by post that we cannot describe it fully, but it is a very highly coloured one, something like ignea, and will, we hope, be a valuable addition to the Water Lilies.

Brodiaea stellaris.—Brodiaeas are deservedly coming into greater favour among those who like variety in their gardens. Among the prettiest here is B. stellaris, a rather dwarf species, with flowers of the deepest purple, but showing a white centre, which forms an effective contrast to the dark colour of the segments. It is only about 6 inches high as grown here, in a rather dry position in the rock garden, with a southern exposure. B. stellaris is a native of California.—S. ARNOTT, Carslhorn, by Dumfries, N.B.

Rose Mme. Alfred Carriere.—One so seldom sees a reference to this Rose that it may not be amiss to remark how beautiful it is in the neighbourhood of Dublin. At Carton it is a great favourite, and Mr. Black, the gardener there, considers it one of the best. At Hamwood, Co. Meath, the delightful garden of Mr. C. R. Hamilton, some exquisite blooms were to be seen on the walls about the middle of June. The flowers were almost pure white and were free from the lumpiness and heaviness of outline to be found in many Roses.—S. ARNOTT.

Swainsonia galegifolia alba is an old and in past years a popular plant, though one not frequent by any means at the present time, notwithstanding its beauty and its freedom of flowering. It is indeed to greenhouse flowering subjects what the well-known Galega officinalis alba is to the herbaceous border, and it is to be regretted it is not more often seen. Treatment similar to that given Genista or Coronilla will be found to suit this beautiful and free-flowering plant, some capital examples of which appeared at the Drill Hall last week from Mr. May, of Edmonton.

Lilium Humboldti magnificum.—A very handsome Lily of much better form than the type, the recurring segments broader and heavily spotted. It is, indeed, a superior form to L. H. Bloomerianum. These Lilies are especially happy in a soil composed equally of peat, leaf soil, and loam, with some sand and about one-fifth of thoroughly decayed manure well incorporated with the bulk. Depth of soil is also important with these, as indeed many Lilies. This handsome Lily was included in Messrs. Wallace's group at the recent meeting of the Royal Horticultural Society.

Eremurus Bungei.—The handsome spikes of this species constitute a very agreeable change among these very striking flowers in the open. Instead of the usual white or delicate flesh-pink of some other kinds we have here the same bold spike densely set with flowers of a clear citron-yellow shade. Such an one will undoubtedly be not only valued in the garden, but should prove useful to the hybridiser. As it is, there is no doubt as to its beauty or extreme worth, and those who saw the handsome spikes that Messrs. Barr brought to the Drill Hall last week could not fail to admire them.

Veronica Zanichelli.—Can anyone tell me the origin of this name, which is that of a Speedwell, distributed from Chiswick to the Royal Horticultural Society's Fellows? It is now in flower here and differs little, if anything, from forms of V. Teucurium often seen. It does not appear to me to be worth retaining under a separate name. The Veronicas are notoriously confused in nomenclature, and a study of various so-called species and hybrids followed or accompanied by that of the names in the "Kew Index" does not tend to enlighten one much. The name here given does not appear in that work.—S. ARNOTT, Carslhorn, by Dumfries, N.B.

Lilium speciosum album novum.—Whether for the open garden or for pot culture, this lovely Lily has no equal among the members of its group. Although pure and beautiful in the chaste and handsome flowers, it does not enter

into competition with the lovely Madonna kind, as unless forced very early it cannot be got into flower till the Madonna kind is on the wane, the above keeping up a succession for some weeks. Some magnificent flowers of it appeared in the hardy plant cut-flower group from Messrs. Collins at the Hampton cottage garden show quite recently, the flowers individually large and very pure.

Rose Gustave Regis.—In my garden I have had La France in magnificent bloom, while Gustave Regis has been remarkably fine. This Rose I find greatly admired by my lady friends; the long pointed buds, of the loveliest shade of pale primrose-yellow, slightly tinged with red, are charming. The flowers when fully open are not very double, but very large and elegant. It is a stout robust grower, with splendid foliage. I hope some of your correspondents will favour us with notes on some of the new Roses you mentioned a week or two ago—I mean Queen Mab, Mons. Cadeau Ramey, &c.—J. L. (*late Hon. Sec. Woodbridge Horticultural Society*).

Exacum macranthum.—Those who have only seen in small plants the unique colour which this lovely plant provides can realise nothing of its marvellous effect when seen with fine heads 18 inches across or perhaps more. Some such examples of it resplendent in the rich royal purple hue that renders it absolutely unique were at the Drill Hall a week ago, the exhibitor being Mr. H. B. May, of Edmonton. The examples in question, a mass of rich blossoms, were upwards of 2 feet high, with an immense corymbose panicle of flowers. It is at once a conspicuous object, of which but too few are seen. As a stove annual it should be grown quickly and freely from the first. The lovely colour and bright yellow stamens should commend it to all.

Iris Kämpferi.—This lovely Japan Iris comes as a fitting finish, so to speak, to the handsome and useful race that has given flowers of indescribable beauty from the earliest days of the year till now. Quite apart from the colour point of view there is a charm in their informal and waving petals that can only be seen in the garden, and best perhaps where the greensward is not too far removed. Moisture during growth they certainly appreciate, but the margin of a lake or pond is no longer a necessity for these gorgeous flowers of July. Given good and deep, thoroughly enriched soil, there is not the slightest reason, if planted in due time, why a considerable measure of success should not result. On quite dry soil with heavy dressings of manure I have grown and flowered this Iris in great numbers and variety.—A GROWER.

A fine Daffodil bulb.—We are sending you a bulb of *Narcissus Emperor* taken from a batch of some 5000 growing here in our grounds. Though we cultivate annually many thousands of *Narcissi* and are familiar with Irish, English, Guernsey, and Dutch grown bulbs, we believe this crop exceeds anything that has ever before been seen here or anywhere else. The bulb sent measures just 1 foot in circumference, and is one out of three which turned the scale at 2 lb. Similar results in the same grounds are obtained with bulbs of the varieties *bicolor Empress* and *Sir Watkin*, which, though yearly very large, this year have increased to mammoth size. Judging from their broad and rich foliage whilst growing and the immense blooms, we expected to see some fine bulbs, but nothing like so phenomenal as is this year the case.—LOUIS VAN HOUTTE, Ghent.

Acantholimon venustum.—This charming alpine is now gay with its pretty pink flowers, the latter much later than usual this year. In very gritty loam the plant offers but little difficulty to the cultivator so far as growing it is concerned, but it is quite another question to talk of increasing it by the usual methods of "cuttings, division, or seeds." I have many times tried to save seed and failed, and am this year taking special precautions in this direction. Fertilisation in the ordinary way appears to be

rendered void by the curious manner the petals have of folding up and recoiling within and deep down into the calyx. The only way of avoiding this is to draw out the petals at an early stage, but in this way also you sacrifice the stamens and of course the anthers, the pistil also at times being either withdrawn or injured. So far I have only succeeded with a very small proportion of cuttings.—E. J.

Salvia cadmica.—Among the seeds sent to this country by our generous friend Mr. Edward Whittall, of Smyrna, were some labelled *Salvia cadmica*. According to the "Index Kewensis" Boissier is the authority for the species, and I think it probable that the plants produced by the seeds sent are quite correctly named. Mr. A. K. Bulley, of West Kirby, Cheshire, flowered this species a year before my plants came into bloom, and was much pleased with it. It has flowered here fer, I think, three summers, and although rather large for the position in which I have it, this Sage is pretty enough to be worth retaining. On rockwork it forms a spreading bush of hoary green leaves with a pronounced, but, to me, not exactly pleasant, odour when touched. The flowers are arranged in long, loose spikes, and are pale lavender in colour with white markings. It is more suitable for the border than for the rock garden. *S. cadmica* comes from Asia Minor and is quite hardy with me. It grows about 2 feet high.—S. ARNOTT, *Cursorthorn, by Dumfries, N.B.*

Notes from Carton, Co. Kildare.—I was at Carton the other day. The Roses, Water Lilies, and the great pergola, built by the late Duchess Hermione, are lovely now. The pergola is 100 yards long, 10 feet wide inside, 14 feet high, and well built and paved with brick. It is topped with peeled Oak and covered with *Spiraeas*, *Roses*, *Vines*, *Clematises*, &c., and the narrow borders inside are furnished with hardy plants in pots. The whole thing is a fresh and beautiful open-air conservatory, and I have seen nothing like it outside of South France and Italy. Its position is good on grass near a row of fine Yews. Every year will see it more beautiful, and it really forms a fitting memorial of one who loved all things beautiful and knew how to grow her flowers. The Rose garden at the cottage is lovely, *Crimson Rambler*, *Brunonis*, *Austrian Copper*, *white ragosa*, and the garden hybrids being very free and bright as backed by the red-tiled roof and the fine old Cedars and Beech trees.—F. W. B.

A note from America.—I wish you could have seen the *Trilliums* in May when they were in bloom. There was literally a bed of them three miles long, and a more beautiful display I doubt if you ever saw. The south sides of the hill are covered with *Bloodroot*, and where the *Trilliums* grow there are acres of *Dicentra cucullaria*. *Rubus odorata* is in full bloom now and will continue flowering until autumn. The foliage and flower of this *Raspberry* are both extremely effective. *Sambucus pubens*—I think you know it in England as *Sambucus racemosa*—although a scarce shrub in this country, is very plentiful just across the river, and is very effective now and will be for some time with its plentiful crop of crimson berries. The common *Elderberry* (*Sambucus canadensis*) is just coming into flower, and often the two species can be seen growing together, the crimson berries of the one contrasting prettily with the white flowers of the other. Wild *Azaleas* we have and *Kalmia latifolia* by the acre, and a week or two ago I discovered large patches of the daintiest of all our wild flowers—the trailing *Arbutus*. Notwithstanding the shyness of this retiring beauty, I have succeeded in establishing a large patch of it in my garden. *Mertensia virginica*, *Phlox divaricata*, *Silene virginica*—in fact, almost all our wild flowers—are very plentiful hereabouts, excepting the *Cypripedium*, of which there does not seem to be any in this neighbourhood. The crowning glory of our spring woods here is the large-flowered white *Dogwood*, and I wish you could have seen about 100 acres of it when it was in

bloom in a wooded ravine about a mile from my house. This ravine is an open wood, and all the undergrowth is *Dogwood*, bushy little trees ranging from 8 feet to 10 feet high up to 20 feet.—J. W. ELLIOTT, *Pittsburg, June 15.*

PUBLIC GARDENS.

Prince George's Ground, Raynes Park.—The Clothworkers Company have given £100 towards the £10,000 which the London Playing Fields Committee are trying to raise to purchase Prince George's Ground, Raynes Park, as a permanent playing field for Londoners of the poorer classes. The total sum secured up to date, including contributions promised conditionally on the purchase being completed, now amounts to nearly £5000.

The Physic Garden at Chelsea.—Mr. Whitmore (Chelsea) asked the hon. member for the Thirsk Division of Yorkshire, as a Charity Commissioner, whether he was aware that the Society of Apothecaries had resolved that it could no longer maintain the Physic Garden at Chelsea; and whether, in view of this decision and in order to preserve this ancient garden, the Charity Commission would be willing to sanction its acquisition by the governing body of the City parochial charities and its subsequent maintenance by them as a botanical garden. Mr. Grant Lawson (York, N.R., Thirsk) in reply said that the Society of Apothecaries as trustees of the Physic Garden at Chelsea have applied to the Charity Commissioners for the establishment of a scheme for the future administration of the trusts regulating the garden, which is now maintained at the charge of their corporate funds, and they desire to be relieved from the trusteeship. The Commissioners have received from the trustees of the London parochial charities an offer to undertake the trusteeship of the garden and to make a provision for its maintenance for the purposes of botanical study, which appears to be sufficient for that purpose. The Commissioners accordingly propose to publish a scheme giving general effect to these proposals.

Foyal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, July 26, in the Drill Hall, James Street, Westminster, from 1 to 5 p.m. Bamboos will be a special feature at this show, and at 3 o'clock Mr. A. B. Freeman-Mitford, C.B., will lecture on the "Economic Uses of Bamboos."

The weather in West Herts.—The past week was the warmest as yet experienced this year. The night temperatures were, as a rule, but little warmer than is seasonable, but on two days the highest readings in shade exceeded 80 degrees. On the 14th the difference between the lowest and highest readings in the thermometer screen amounted to as much as 32 degrees. At the present time the soil both at 1 foot and 2 feet deep is about 2 degrees warmer than the July average. A tenth of an inch of rain fell during the early morning hours of the 19th, but previous to this none had fallen for more than a fortnight. No rain water at all has come through the 2½ feet of soil in either of my percolation gauges for nearly a week. During the five days ending the 18th the sun shone brightly on an average for over eleven hours a day.—E. M., *Berkhamsted.*

Clematises dying off.—I bought a full collection of *Clematises* early in the year from one of the houses most famous for them, and I am sorry to say they are all dying off one by one, sometimes quite suddenly. They are planted in newly-made and deep soil, in the best situations, against walls and corners. Can any of your readers kindly tell me what they think is the cause of this?—V.

Names of plants.—*J. Crook*—*Clematis recta*.—*Hugh White*.—*Oncidium crispum*.—*A. K.*—*Serapias cordigera*.—*W. O. H.*—*Lathyrus sativus var. ceruleus* (see *THE GARDEN*, p. 40).—*F. M. B.*—Looks like *Helianthus decapetalus*, but would like to know height.—*W. O. H.*—1, the common Bugloss; 2, *Cotyledon umbilicus*.

ORCHARD AND FRUIT GARDEN.

STRAWBERRY FORCING.

FORCED Strawberries are much valued here, and I grow about 1000 plants. For the first lot I grow La Grosse Suerce and Royal Sovereign. The latter I use for succession, including a batch or two of Laxton's Noble, the fruit of which is handsome, but lacking flavour and substance. Royal Sovereign is a much superior fruit, as we get size, flavour, good colour, firm flesh, and it is a splendid cropper. It is very important to have strong and well matured plants. I layer into small pieces of turf about 3 inches square which has been stacked long enough to kill vegetation. The best runners are obtained from plants put out the previous year. If the soil is kept moist the runners will be ready to be detached from the parent plants in three weeks, when the bits of turf will be well filled with roots. If placed in a shady place and syringed every morning and evening in dry weather, they will be ready for potting in a week. Six-inch pots are employed for all plants, good drainage being given, with a small handful of half-inch bones over the drainage. The soil consists of loam of a friable nature. To one barrow-load are added a 6-inch potful of soot, an 8-inch potful of fine bones and a sprinkling of wood ashes. A few rough pieces of the potting compost are placed over the crocks, using the potting stick freely. When the plant is potted, the base of the crown is 1 inch below the top of the pot. It is well to be particular over the state of soil as to its proper moisture and to keep the plants well up, the base of the crown showing clearly. It is very important to grow the plants fully exposed to all sun possible and shelter from the strong winds, also to have a good depth of ashes or loose gravel to stand them on. Watering is well attended to, but judgment should be used at all times, as too much soon causes an unhealthy appearance. My plants are watered twice daily in fine weather. I commence feeding slightly when

the pots are well filled with roots by giving soot water about twice a week. Two or three weeks after, they have liquid manure from the cow shed twice a week if fine weather, and occasionally a pinch of guano, which I find an excellent manure for Strawberries. Great attention is paid to all side buds that appear. When they become prominent enough they are rubbed out, which is generally about the latter end of August or beginning of September. This will lead to the development of the entire centre crown, and good strong flower-spikes will result when the plants are introduced into heat. About November I have all the plants plunged to the rims in ashes in some sheltered spot under a wall. I do not believe in wintering plants in cold frames or stacking them on their sides. Light is the most important of all things, especially when the days are short. I have no Strawberry house proper, but have shelves fixed in vinerics and Peach houses, in three-quarter span-roofed houses, about 3 feet from the ridge. These houses give plenty of light. The plants grow sturdy and throw up strong spikes of flower.

Before bringing the plants into heat (first batch January 1) they are thoroughly overhauled. The temperature of newly-started vinerics is very suitable for starting the Strawberries into growth—40° at night and from 45° to 50° by day. This temperature is continued for about a fortnight, then gradually raised to 50° by night and 55° by day. Increase the heat after the fruit is set by 5°, after about a fortnight increase till you reach 65° by night and 70° to 75° by day; sun 85° to 90°. I find it very necessary, to finish the fruit, to have a drier and more airy house than it is beneficial to allow a vinery to become. As soon as the fruit is partially coloured the plants must be moved and given more air and a fairly dry warm atmosphere, say 60° by night and 70° by day; this adds very much to the flavour of the fruit. Strawberries, like many other kinds of fruit, require very careful ventilation, otherwise mildew is sure to appear. I allow a little air on

all night, according to the weather. The syringe should be used cautiously, never syringing in dull weather. Twice a day is quite sufficient on bright days, early morning and closing time. Should the foliage be wet from the morning syringing, avoid wetting it again at closing time; damping the floor will suffice. Discontinue when the plants are in flower (unless very sunny weather, when I believe in syringing occasionally at closing time) and when the fruit commences colouring. I do not believe in feeding too soon. I give weak soot-water once or twice a week only until they have set their fruit; after, I feed more liberally by giving liquid manure twice a week with a pinch of guano once a week. I discontinue when I see signs of colour. I always allow on each plant fourteen or sixteen fruits, and plants well treated will swell this number off to a good size. Green fly and mildew are the worst enemies. For green fly I fumigate. If troubled with mildew, dip all plants directly the fruits are set in a mixture of lime and flowers of sulphur—one pound of each boiled in 2 gallons of water and allowed to cool down. Use half a pint to 4 gallons of water.

Gardiner, N. Wales.

W. COATES.

Melon Diamond Jubilee.—In appearance this Melon bears a striking resemblance to Countess, which is really one of its parents, the other being Best of All. Like the Countess it is a wonderfully free cropper, very lateral showing a fruit. It is an oblong-shaped sort, golden yellow in colour, and although stated to be a netted variety, all the fruits produced here have been quite smooth. It has white flesh, which is of good average depth, is very tender, and the flavour is excellent. It also ripens quickly, a great desideratum in a private garden, while it is well adapted for growing in cordon form either for early or late work.—A. W.

Strawberry Lady Suffield.—I am sending you a sample of my last new Strawberry, Lady Suffield. I have also included Lord Suffield for comparison. The new Strawberry was obtained from Empress and Lord Suffield, combining, as I think, the high flavour of the Empress with the

delicious sweetness of Lord Suffield. It ripens before Lord Suffield by a week, thus taking after the Empress in earliness. It is a very firm fruit and a most profuse bearer. I think in Lady Suffield I have taken a decided step in combining the high, fine flavour of Empress with the delicious sweetness of Lord Suffield. It is a most profuse bearer, fruit very firm, and travels well.—W.M. ALLAN, *Guntton Park, Norwich.*

NOTES ON STRAWBERRIES.

THIS has been far from a good Strawberry season here, as many of the first blossoms went blind through want of sunlight and the miserably dull, wet, and cold weather which obtained most of the time while the plants were flowering, and also when the early fruits were ripening. For a fortnight or so we hardly saw a glimpse of sunshine, consequently no bees or other fertilising insects were flying, and the pollen being almost continually wet and cold could not act. Out of the older varieties grown, only Auguste Boisselot, President, Vicomtesse H. de Thury, and Latest of All have been really good. The last mentioned, having benefited by the change for the better experienced in the weather, is now excellent, as, too, is Dr. Hogg. Royal Sovereign has disappointed me much, or rather it has confirmed the note of warning which I wrote last year as to extensive planting for outdoor work, for the fruits have rotted wholesale on the plants and the flavour has been poor, want of sun having intensified the natural acidity of the fruit and prevented the rich flavour from developing. I believe that Royal Sovereign is better for a very open situation than it is for a closed-in garden, the leafage made in the latter position being altogether too rank and overpowering, even on year-old plants, to allow of the proper ripening of the fruit in a dull and wet season. Probably the very best place for the variety in question is under glass, and for forcing it has been found first-rate.

Some considerable space has been given to year-old plants of many varieties, and most of these were planted out on a wall border exposed to the south, the plants being well rooted and planted early in August, so that they had every chance of doing well. Well in front of all others has been Laxton's Leader, and to this I can give unqualified praise from all points of view. It bore a big crop of fine fruits, many of the latter running to 2 ozs. weight each, beautifully coloured and the flavour first-rate. I was not quite prepared to find it so good, as I had read of its being inferior as to flavour, but on this light soil nothing could be much better, and I place it on a level with President in this respect and well before it as to size and cropping, while the leafage is not nearly so ample, though the plant is hardy and robust enough. I am fully expecting that this will turn out a standard variety, good enough for anyone to eat at any time, and one that can be grown with a certainty of a good paying crop, which is more than can be said of many of the best flavoured varieties. Of Monarch, I can give no such good account. I found it very shy indeed, and many of the plants went blind: the few fruits borne were of good shape and colour, very glossy and firm, the flavour only moderate. It will be grown again as a two-year-old. Laxton's No. 1 was the earliest grown. The fruits were small and soft, of a Keens' Seedling flavour and shape, but far behind those of that old variety in quality. It makes ample leafage that well protects the blossoms, but in spite of its earliness it will not be grown again. Countess gave but a poor crop of rather small fruits; these were well

shaped, firm, and of good flavour, but not so good as some others, and it will have to make room for something else which will give a better return. Among those which gave a good crop was Cumberland Triomphe. This is a big round Strawberry of excellent flavour, rather early, but very soft and woolly in texture. Baron Brisse is very similar to the foregoing in general appearance, excellent in flavour, of fair texture, and rather late. It did not give a big crop, but will get another trial as a two-year-old, and until then I must reserve judgment on it. Frogmore Late Pine, an old favourite, is far from a good cropper at any time, but its excellent flavour keeps it a place; as a one-year-old plant, however, it is found by me next to useless.

J. C. TALLACK.

Peach Exquisite is, I think, not so generally known and cultivated as it deserves to be, as it is far superior in quality to many other late varieties, and in my opinion the best of all the yellow-fleshed Peaches. The tree possesses a good hardy constitution, is a vigorous grower, and a free setter. It is an excellent kind to grow, either in a mid-season or late house, coming into use, as it does, between Princess of Wales and Walburton Admirable. It is, however, of much richer flavour than the two kinds just alluded to, while it equals them in point of size, the fruits attaining very large dimensions. The skin of Exquisite is pale yellow, mottled with red next the sun. The flesh is also pale yellow, streaked with red, more particularly next the stone, and it is tender, juicy, and richly flavoured.—A. W.

Strawberry Leader.—Those who force Strawberries should give Leader a trial, as it is a grand fruit and not lacking in quality. Its size cannot be complained of, as it may be termed large, and, what is so desirable in a forced Strawberry, it has firm flesh of a dark scarlet colour with good flavour. It forces well and sets very freely in a moist house; indeed, it is not unlike Royal Sovereign as regards its growth. Growers may ask, Why grow Leader when Royal Sovereign is so good? Leader is later than Sovereign, and being so distinct in flavour it is well worth room in all gardens. It is excellent for open-air culture, as it comes in just at a time the earlier ones are on the wane. As a mid-season Strawberry it should find favour. This season I am much pleased with the good quality of its fruits.—G. WYTHES.

Strawberry Latest of All.—This produces enormous fruits of the richest and most exquisite flavour, but the name is misleading, as I gathered ripe fruits of it the first week in July this somewhat late season. But, whenever they come, such splendid fruits are welcome and are bound to command admiration. Not being a particularly vigorous grower, Latest of All may be planted rather more closely than the majority of kinds, and as runners are not very freely produced until somewhat late in the season, the lines, if planted too far apart, have a rather bare appearance. But there is no question as to its value here on a heavy strong soil. The fruit is very firm and travels well. The points of the fruit are occasionally somewhat pale in colour and are all the better for a night in the fruit room before being eaten. Its pale green foliage is very distinct.—H. R.

Strawberry Monarch.—Last season I wrote rather disparagingly of this variety: not that the fruits were not large enough, or that the plants had any fault of growth, but simply owing to lack of flavour. It is little short of remarkable that, in such a season as we had here, with drenching rains right up to the time the fruit was ripening, the flavour should have improved; but it is none the less the fact, and in all probability Monarch will be best in wet seasons. Since the first fruits were gathered we have had

more reasonable weather, and the fruit has been splendid, not only from young beds—though these were naturally the finest—but also from two-year-old plants. With good culture and plenty of room it is doubtless a very fine strawberry, and, according to the present year's experience, of far better flavour than Royal Sovereign.—H.

RASPBERRIES.

WHILE no fruit pays better for good culture than the Raspberry, the fair results produced by an amateur or beginner with a few old stools or rows at his command show that it is easily grown. The let-alone plan, in fact, is so satisfactory to a certain extent that no fruit is more likely to be neglected year after year, the gathering of the fruit and thinning out of the old canes being all the attention they get in many places. The soil in which they are grown has a lot to do with continued success, and a fairly heavy yet well-drained soil cannot easily be beaten. Even in gardens of some pretensions there is a disposition to fight shy of disturbing old Raspberry quarters and planting new ones, yet if gone about in the proper way and at the correct season the work is as easy and the result as sure as making a new Strawberry bed. The suckers that spring up at some distance from the older stems are the most easily detached and best for planting, and the safest time for the work is early autumn while there is plenty of warmth in the soil and yet little fear of long-continued drought.

For private gardens there are many suitable methods of training, but I question if any give less trouble than a wire at about 3 feet from the ground, the canes being planted a foot apart and tied to the wire. Where much exposed, two wires are best, one at 2 feet from the ground, the other at 4 feet, this steadying the canes, which may be allowed to run higher than the top wire if the lines are set at a good distance apart. The land of course will have been in order long enough to have got nicely settled, and planting must be followed by a mulch of short manure.

The depth at which the roots are set depends a great deal on the nature of the soil, but shallow rather than deep planting should be the rule. This because the Raspberry roots deeply with the lower tiers of roots, and seems by the nature of the upper, more fibrous, parts to delight in running just under the surface. The long thong-like roots steady the plants in position, while those nearer the surface collect food and moisture. For this reason they should be kept up, well spread out and as far as possible kept always moist. In early spring these planting canes should be cut down to within a few inches of the surface, and as soon as strong sucker-like growths appear from the base the little lateral shoots may be rubbed quite out, even from the few joints left. The care of the grower will be by all reasonable means to ensure a strong, healthy, and clean growth, that in the succeeding season will carry a fair crop of fruit. The second season, if properly treated, a very heavy crop will be gathered, and after this the plants should go on improving for several years. Pruning consists, of course, in taking out the old wood after fruiting, and so thinning the number of young shoots annually that there is no crowding on the trellis. The old canes are best removed directly the fruit is taken, the additional room being useful, allowing sun and air to enter freely and thoroughly ripen the young canes. A heavier crop of fruit may in some instances be gathered by topping the young canes to different lengths

in spring, not indiscriminately as they come, but leaving the stronger canes a foot or even more longer than shorter or imperfectly ripened ones. A more regular supply of fruit down the trellis and a heavier crop, owing to each separate cane being taken at the most suitable height, result. Perennial weeds are a great nuisance in Raspberry quarters, as they run in and out among the canes where they are difficult to get at. It is worth while on this account being at a little trouble in cleaning the land before planting, and, by frequent stirring of the surface, keeping all such as wild Convolvulus, Twitch, and Thistles in check.

As mentioned above, the Raspberry pays for good feeding, and a liberal dressing of the surface annually is well repaid by the improved yield of fruit. The mulch need not be all farmyard or stable manure. There are many things that are useful, such as potting-bench refuse and the soil from the decaying of garden refuse and a little lime.

Melon The Czar.—A short time ago I had occasion to mention in these columns that I had three new varieties of Melons on trial, the above being one of the trio. Since then the fruits have matured, and when tested proved to be all that one could desire. The plant is a strong grower, but not perhaps quite so prolific as some other sorts I am acquainted with. The fruits are, however, of fine proportions, round in shape, and averaging about 5 lbs. in weight, while the skin is pale yellow and slightly netted. The flesh is white, of great depth, edible quite up to the rind, and very rich and deliciously flavoured. I do not know its parentage, but it certainly is a first-rate sort and one worthy of cultivation. Having to meet a large demand for Melons, I always give new introductions a trial as they are sent out, some of which prove satisfactory and others quite the reverse. The above, however, possesses all the good qualities claimed for it by the vendors, and will therefore be grown again and in quantity.—A. W.

Peach Salway.—I am glad to see that Mr. Iggulden, in his note on "Peaches and Nectarines for Market," has a good word to say in favour of this much-maligned Peach. Owing perhaps to the situation here being a good one for outdoor Peaches, Salway generally does well on a south wall. By this I do not wish to infer that the flavour is first-rate, because it is not; but the fruits grow to a large size, they are very handsome, and it certainly is a valuable Peach for late work. It ripens with me outdoors about the middle or third week in October, and, as Mr. Iggulden justly remarks, it keeps well, and at that season of the year is invaluable for dessert. For some reason my tree has missed bearing this season, although it blossomed well and had apparently set a good crop. The blooms, however, dropped in a wholesale manner, a thing I have never known to happen before. What makes it more remarkable is the fact that other trees near by on the same wall and grown under precisely the same conditions are carrying good crops of fruit.—S. E. P.

Apple Cox's Pomona.—This richly coloured and handsome Apple may justly be termed as "accommodating," so well does it submit to being cultivated in any form of tree, while it is also exceedingly prolific. Another point to be advanced in its favour is the fact of its being a very consistent bearer, as it but seldom misses fruiting. The fruits are of medium size, but most abundantly produced. It is a very profitable sort, and one on which dependence can be placed for market work, the rich, highly coloured fruit always meeting with a ready sale either privately or otherwise. When grown for private use it is equally good either for the table or cooking. The smallest and most richly coloured fruits should be reserved for table use. They form a

handsome dish, and are much admired for their beauty. The flavour is also rich, and the soft flesh is much appreciated by many people, or by those who are unable to partake of firm, crisp eating Apples. When grown entirely for private consumption the fruits should not be gathered until they part readily from the tree, otherwise they will lack flavour and be dry-eating. For marketing it is necessary to gather the fruits before they become tender for reasons which are only too obvious.—A. W.

Cherry Elton.—This Cherry succeeds remarkably well as a standard, as it seldom fails to produce a full crop of its large luscious fruits. In an orchard the fruit comes into use about mid-July, but when grown on an east wall it is quite a fortnight earlier. It hangs well, so that if not required at the time it ripens, wall trees can be netted over to secure the fruit from bird attacks. If allowed to hang until they are on the point of shrivelling the fruits are delicious. It is a vigorous and hardy grower, and standards soon form good spreading heads. Intending planters should make a note of this, as it is a sort which can be planted with confidence. A few days ago I had occasion to pass through a Cherry orchard in which several trees of this variety were carrying good crops of fruit. This orchard occupies a high and dry situation, it having been formed on the side of a hill, and is so well elevated above the surrounding country that it is free from fog and almost wholly so from frost effects. The upper portion of the hill forms a fine protection to the orchard, and effectually shields it from the north and east, while the land slopes rather abruptly towards the south-west. The soil is a shallow loam, overlying limestone, and with its small particles of the decayed rock are freely commingled. In spite of the situation and the weather being hot and dry, the fruit borne by the trees was first-rate in every respect and not at all dry eating, as I quite expected to find. This shows that Cherries do not need the same amount of moisture as many of our other hardy fruits, as rain drains away quickly in such a position as that occupied by the orchard described. My chief object in mentioning the matter, however, was to draw attention to the fact of Cherries succeeding so well in such a position, and there are, doubtless, many more such positions, not only in this county, but in others suited to hardy fruit culture, which might be profitably utilised.—A. W., *Hereford.*

NOTES AND QUESTIONS.—FRUIT.

Melon Countess of Derby.—This Melon was, I believe, the result of a cross between William Tillery and Knowsley Favourite. The progeny has green flesh and is richly flavoured. The fruits are not unlike those of Diamond Jubilee in shape, but the colour is paler and the skin is also netted. It is a vigorous grower, a good cropper, and the fruit matures in from fourteen to sixteen weeks from the time of sowing, a fact which should be noted by all who have to produce early Melons.—A. W.

An early Strawberry.—My earliest Strawberry this year was Early Laxton, and though the fruits are small they are of excellent flavour. A few persons object to large fruits, and these may with advantage grow the above variety, as it produces a great quantity of fruit, but none large; indeed, the later gatherings are small and just the size for preserving. The fruits are of a rich crimson colour, and being firm travel well. This variety was ripe ten days earlier than any other kind. Early Laxton was gathered in the middle of June, and in quantity the third week, when other early kinds were only just turning. For market I do not advise its culture, as its size would be against it. On the other hand, it forces well, doing grandly in a cold frame. Of late we have paid a good deal of attention to mere size; here is a break in the right direction, and in

Early Laxton will be found good quality and earliness.—G. W. S.

Strawberry Louis Gauthier. This is doing grandly this year in anything but a good Strawberry soil, and being a late cropper will prove of great value in gardens where these fruits are needed for a long period. Some growers may object to the colour of the fruits when ripe, this being of a peculiar blush shade or a very pale pink; indeed the nearest approach in colour is the White Knight, but superior to that variety. Louis Gauthier is a good cropper, a strong grower, and as it produces an early crop at the end of June or early in July and another in two months' time, it will be a distinct gain in gardens of limited size where many varieties cannot be grown. The second crop is borne on the new growths made now. It is not advisable to cut away runner growths; they may be thinned, and will bear fruit freely in the autumn. Mr. Hudson, Gunnersbury House, grows this variety and speaks highly of its qualities. It is of continental origin and does well in light soils.—G. WYTHES.

Apple Crimson Queening.—I can never understand why this Apple is not among the best known varieties, but one rarely sees a note on it. It is excellent for cooking at any time while in season, and selected fruits are first rate for dessert, handsome in colour, crisp, juicy, refreshing, and highly flavoured. The tree is a very healthy, spreading and robust grower and a sure cropper. The fruits are medium to large sized, conical, with high crown and well-defined ribs, crimson striped on a bright yellow ground when ripe. It is unfortunate it comes into use with the bulk of early Apples and not early enough to give it an especial value on that score, but it remains in season for at least three months, and I use it largely for dessert during the latter half of September and in October before commencing on the Ribston Pippin. If confined to a small orchard and a very limited number of varieties, I should certainly give this a place, with the assurance of having a free-bearing and healthy-growing tree.—J. C. T.

THE MARKET GARDEN.

PEACHES AND NECTARINES FOR MARKET.

PLANTING THE TREES.

TRAINED trees or those that have been pruned about three times and duly trained are too often preferred under the impression that they are the cheapest in the end, owing to their attaining to a productive state the most quickly. No greater mistake in connection with Peach and Nectarine culture can well be made. Trained trees rarely, if ever, produce fruit during the season following planting. They might do so if previously growing against sunny walls and extra pains were taken in transplanting before all the leaves had fallen. As it happens, the trees are principally raised in the open ground and the wood is not of a fruitful description. According to my experience, trained trees are apt to be slow in attaining to a productive state, and are most liable to lose their branches prematurely and piecemeal owing to their gunning badly where so much severe pruning of rank, immature wood took place. Maidens, or trees that have made one season's growth from the bud and not been pruned in any way, are much the cheapest and by far the best to plant. These may be planted during winter or early in the spring and fruited the second summer after. To be plain, if I planted maidens in February or March next—and that I hold to be a good time to do this work—I should expect

them to form fairly large heads during the following summer capable, say, of producing a dozen fruits in 1900, the trees benefiting rather than suffering injury from the early cropping, as it prevents grossness. Strong, well-ripened maiden trees should be bought always from a reliable source, paying the best (trade) price for them. If received in the autumn they may be planted then, or they can be laid in by their heels, taking care to well cover the roots with fine soil and to mat over the tops whenever a severe frost is anticipated. Just when top growth commences is about the best time to plant, and this delay admits of the house or houses being utilised to their full extent for Chrysanthemums and the preparation if need be of many thousand Tomato plants. I ought, perhaps, to have pointed out that expensive curvilinear wire trellises are what answer well in private gardens. Wires strained through eyes screwed into the sash-bars lengthways of the house 9 inches apart and 9 inches or rather less from the glass is, however, the cheapest, simplest, and best arrangement. My trees are about 13 feet apart, but a portion would soon occupy double their allotted space if I could make up my mind to sacrifice the other half of them. For quick returns, plant nearly or quite as thickly as I have done. They can be kept within bounds by judicious stopping and shortening. If large trees are desired, either allow more room in the first instance, or else plant more thickly and transplant some of them to another house when they are nearing each other. There is yet another alternative. Cordons may be grown between fan-shaped trees, and these gradually cleared out as more space is required. I have been advised by an expert that cordon Peach and Nectarine trees planted 2 feet or so apart are very profitable. I hope to be able to say more about that some other time, as my three dozen cordons are only just beginning to bear fruit. Trees "worked" high or with a clear stem are expensive, and, to tell the truth, the shorter the Plum stock the better pleased I am. The best stems are formed by the scions, and if Peaches and Nectarines were all either on their own roots or budded on seedling Peaches there would be fewer failures owing to the stock not swelling properly. We want free, not dwarfing stocks. Stems reaching to the lower wire or from 2 feet to 3 feet high can be had by planting strong dwarf maidens. Top these to the desired height and trim off all lateral growth, leaving nothing but so many "sticks," as a gardening friend once termed my newly-pruned maidens. If the trees are properly planted, taking care not to bury the collars deeply, are kept uniformly moist at the roots and not submitted to hard forcing at first they will break strongly, and what the grower then has to do is to remove the worst placed of the shoots, reserving four or six for laying the foundation of the tree. If these shoots grow strongly, as they usually do, top them when about 18 inches long, thin out resulting shoots and lay in those best situated for the purpose. In this way a fair sized head is formed during the first season, and the wood not being too gross will flower freely the following spring. Gentle heat, with a daily syringing to keep down red spider, is all that is necessary for these young trees. If Tomatoes are grown with them—and no market grower could well resist the temptation to thus turn the space to a good account for at least two seasons—the syringing should be done in the morning after a little air has been given, and there must be no early closing to box up sun-heat, as this means a sudden bad attack of Cladisporium and a light crop of Tomatoes. The Tomatoes ought also to be studied during the

second season, the Peach and Nectarine trees making good progress unless neglected, also fruiting well in the hot and comparatively dry atmosphere that suits the Tomato plant.

TREATMENT OF OLDER TREES.

I believe in thinning out crowded shoots, pruning or shortening those reserved requiring strengthening, and those already tending to grossness lightly. Older trees should be shortened freely to keep them within bounds and to strengthen the centres, as these ought to be as well furnished with bearing wood as the rest of the trees. A close look-out should be kept for fastenings becoming too tight, as I have seen much harm result from a neglect of this precaution. There ought to be no necessity for winter dressings with insecticides. Applying these occupies too much time, and besides the only insect pest that, as a rule, proves troublesome in the case of market growers' trees is red spider. If these have been in the ascendant during the summer previous, thoroughly wet every part of the dormant tree with water to every gallon of which a good-sized handful of sulphur has been added. If the trees are kept properly syringed and the borders constantly moist, red spider will make but little headway, and after the crops are gathered, syringing with sulphur and water, wetting as much of the under side of the foliage as possible and discontinuing the daily syringing, with clear water, effectually checks red spider. Flowers of sulphur mix readily with water if squeezed through a muslin bag. Large trees bearing heavy crops of fruit should be assisted by frequent applications of liquid manure to the roots, and in no case ought the borders to become dry either during the growing or resting periods. Neglecting the borders after the trees have matured their crops is anything but sensible. It is during the next few months that they recoup their strength and the foundation for another crop is laid.

MARKETING THE FRUIT.

If any of my readers have left such numbers of fruit on the trees that many of them refuse to swell and ripen properly, dropping prematurely, the chances are the remainder will not realise high prices, and the trees will have been much crippled into the bargain. Leaving large numbers of fruit at thinning-time with the idea that some will always drop prematurely is the surest way of bringing about this misfortune. Do all the thinning necessary before the stoning period, and if the trees are in good health there will be no premature dropping to complain of. What constitutes a good crop is somewhat difficult to define, but if the fruits are left 9 inches apart each way all over the trees there will not be much wrong either way. If left much closer together there will be many more "seconds" than "firsts." If Nectarines are smaller than Peaches, it does not follow that the fruits may be left any closer together on the trees. It is my belief each Nectarine takes as much out of a tree as a Peach, and if this view were generally acted upon, very many more fully developed Nectarines would be met with in both market and private gardens. I believe half the Nectarines grown in this country are uneatable, owing to the trees producing them being over-cropped. When thinning Peaches or Nectarines, as many as possible should be left on the upper surface of the trees, and all ought to be well exposed to light, air and sun to colour them—pale fruit not pleasing buyers. Some there are who grow good fruit only to spoil it in packing. It should be borne in mind that Peaches and Nectarines ready for

the dining table when packed would be comparatively worthless by the time fruiterers get them, and that however well they may be packed. The time-honoured, but in all instances foolish, plan of suspending fish-nets under the trees to catch falling fruit should never be adopted by market growers. No fruit ought to be left on the trees till ready to drop, as this militates against the quality as well as travelling. Once or twice every day the trees should be gone over, and every fruit just commencing to soften at the base (they must not be pressed anywhere else) ought to be at once carefully, yet forcibly, removed. They may be packed at once or kept resting on a bed of paper and wood wool till they can be packed. If quite firm when started, they will soften somewhat during the journey, and a few hours in a shop window will do the rest. The sender will also do well to grade all his fruit. Never spoil a good gathering by including a few second or undersized fruit with the prime, as this may end in a low price being allowed for all sent. Faulty grading and packing tell their own tale to the commission agent, and advantage may be taken of the inexperienced sender as a consequence. On one occasion this season I had occasion to make three grades, and the returns were respectively 18s., 12s., and 6s. per dozen, or the respectable average of 12s. per dozen. If all had been sent without grading, 9s. would have been the most per dozen returned. Cheap, fragile, or makeshift boxes ought never to be used. Those who send to salesmen should apply for their boxes and pack in these. Home-made boxes ought to be equally as deep and strong, fruit frequently coming to grief in shallow boxes particularly. Nothing hard should press against the points of Peaches and Nectarines, and they ought to rest on a soft, springy base. A box 19 inches long, 14 inches wide, and 4½ inches deep, outside measurement, answers well for two dozen large Peaches, and will hold half a dozen more smaller-sized fruit or Nectarines. Wood-wool has largely superseded cotton-wool for packing, but I do not pack wholly in this, for the simple reason that Peaches and Nectarines are apt to shift in this material, sometimes arriving at their destination resting on their points instead of their base, where, if slightly bruised, it does not greatly detract from the value of the fruit. A layer of cotton-wool may well be placed in the bottom of the box as a foundation only. Each fruit should be placed in the centre of a square of tissue paper, bringing the ends up to a point on the top. Cotton-wool, unbleached, but of fairly good quality, pulled or cut into lengths of about 12 inches, and each width divided into three strips, folded so as to have the skin side outwards, should then be wound round each fruit, and, the cotton-wool being deeper than the Peaches or Nectarines, serves as a rest for the base and a protection for the point. The fruit ought to be packed closely and tightly together, and may, further, have a thin or thick layer of cotton-wool, as the case may be, over the top, the lid shutting down tightly on this. Thus packed not much harm should result, even if a railway porter did drop the box in handling. There ought to be no nailing down of the lids, as it is uncalled for. The fruit may, and very frequently is, damaged in trying to force open nailed-down lids, and packers are far too fond of driving in those wire nails. It is well to paste printed labels on the boxes, showing what the contents are, or intimating that the fruit is soft, and the number and quality of the fruit should also be stated openly for the benefit of salesmen.

W. JAGULDEN.

TREES AND SHRUBS.

PIERIS FORMOSA.

THE genus *Pieris* is represented in gardens by some half-a-dozen species, the best known of which are *P. floribunda* from the South United States and *P. japonica* from Japan. Both these are well-known evergreen shrubs, but are generally called *Andromedas*. The genus also contains two or three deciduous species. *P. formosa*, the species now figured, is one of the rarest: it is evergreen, and comes from the mountains of Northern India, where it is found at altitudes of 7000 feet to 10,000 feet, and from China. There it grows some 12 feet high, and is a wide-spreading bush or even a small tree. In England, unfortunately, it is not really hardy except in the south-west, or in localities with a similar climate. It has been grown outside at Kew for many years, but now it is only

diameter; they are nodding, a quarter of an inch wide at the base, tapering towards the narrow mouth, where are five small reflexed lobes. The colour is a porcelain-white. For gardens ordinarily situated near London and further north this plant is of no value as a hardy shrub; it requires the protection of a cool greenhouse; but wherever *Rhododendrons* of the stamp of *Falconeri*, *grande*, &c., will thrive outside, it ought always to be planted. Its general character as well as its great beauty when in bloom are admirably shown in the accompanying engraving.—W. J. B.

Mr. John D. Nauscawen, Whiteway, Chudleigh, Devon, who sent us the photo from which the illustration was prepared, sends us the following notes on the plant:—

I enclose a photo of *Andromeda* (*Pieris*) *formosa*. It is 17 feet high and 28 feet through. As you see, it is one mass of bloom, and certainly one of the loveliest plants for the shrubbery that ever

was *Philesia buxifolia*, which was bearing a quantity of its red *Lupageria*-like blossoms.—S. W. F.

Tree *Elaeagnus*.—Generally speaking, the different kinds of *Elaeagnus* that are hardy in this country can be divided into two groups, by far the better known being the shrubby forms of an evergreen or sub-evergreen character, which are natives principally of Japan. Besides these there are others which attain quite tree-like dimensions. They are all natives of South-eastern Europe and Asia Minor and are deciduous. The principal species, *E. Hortensia*, though very uncommon, was introduced into this country over two centuries ago. The variety *angustifolia*, which is one of the very best, has the leaves particularly long and Willow-like; indeed, all of them bear a certain amount of general resemblance to a Willow. The one prominent feature of these *Elaeagnus*s, or *Tree Olives*, as they are also called, is the beautiful silvery character of their foliage, and on this account they stand out conspicuously from other trees, more especially when the slender branches are stirred by the wind, as then the intense silvery under sides of the leaves are brought into view. These *Elaeagnus*s are well suited for dry, sandy soils, for not only do they resist drought well, but the silvery character of the foliage is more pronounced than where the soil is moister and of better quality.—T.

***Robinia hispida*.**—We have in our gardens a great wealth of spring-flowering trees and shrubs, but after they are past the number of subjects in bloom is far more limited, and consequently any that flower then are additionally valuable. Such an one is the *Rose Acacia* (*Robinia hispida*), which, although far less in stature than the other cultivated species of the genus, occupies the first place if regarded from a flowering point of view. It is of a loose, shrubby style of growth. The rich rosy purple pea-shaped blossoms are borne in considerable numbers, and being so distinct in colour from those of any of their associates they are particularly valuable. This *Acacia* is nearly always met with grafted on to the common *False Acacia*, hence it is very rarely seen in its natural bushy shape. If so grown, rough winds would have less effect upon it than when grafted on to a clear stem, as is usually done. Under these latter conditions it must be planted in a fairly sheltered position, as the branches being brittle they are easily broken by rough winds. The specific name of *hispida* is derived from the stiff hairs with which the young branches and flower-stalks are thickly clothed, but all the individuals do not possess this character to the same degree—indeed, there is a form—inermis—in which it is altogether wanting. A group consisting of a few plants of this *Acacia* on its own roots and thus showing its natural habit, should form a most attractive feature in a garden, but it is doubtful if such plants can be obtained.—T.

Pieris formosa at Pentillie Castle, Cornwall. From a photograph sent by Mr. John D. Nauscawen, Whiteway, Chudleigh, Devon.

3 feet high, and this growth has for the most part been made during the last two years, the winters having been mild enough to allow the shoots to survive. The winter of 1894-5 had completely cut it back to the ground. In a word, *Pieris formosa* stands on the same footing as regards hardiness as the tenderer species of Himalayan *Rhododendrons*, except that it has the faculty of sending up growths when killed down to the ground. In Cornwall a few years ago I saw fine specimens of this evergreen, and it is in some such locality, no doubt, that the magnificent specimen shown in the illustration has grown.

The leaves are somewhat like those of the *Portugal Laurel*, although slightly firmer; they are each 3 inches to 5 inches long, from 1 inch to 1½ inches wide, tapering towards both ends, of a dark lustrous green, perfectly smooth, and have the margins very minutely toothed. It blossoms during April and May, the flowers appearing in great numbers on a compound panicle 6 inches or more in length and in

was introduced. The plant is growing in the grounds of Mr. W. Coryton, Pentillie Castle, Cornwall, where there is a grand collection of Indian *Rhododendrons*.

***Crinodendron Hookeri*.**—There have of late been several references to the above Chilean shrub as an open-air subject in Great Britain. It is generally looked upon as too tender for outdoor culture in this country, and is in consequence most often seen as a denizen of the greenhouse, though in the southern counties there are instances of its doing well in sheltered positions in the open, I myself having seen a healthy plant in blossom during the past month in a well-known garden in Dorsetshire. That it should flourish without protection in a garden as far north as *Ross-shire* is, however, certainly surprising. In all probability the site that it occupies is naturally protected from cold winds by rocks or evergreens or it could hardly be expected to endure Scottish winters with impunity. Another Chilean shrub that I noticed in bloom in the garden I have already referred to

NOTES & QUESTIONS.—TREES & SHRUBS.

***Ribes speciosum*.**—A note on the *Fuchsia Currant* growing in bush form appeared some few weeks ago. Naturalised on the grass in a fairly open but sheltered position, its arching shoots thickly set with pendent blossoms of glowing crimson, it was a beautiful sight during the past spring in South Devon and remained in bloom for many weeks.—S. W. F.

***Ozothamnus rosmarinifolius*.**—On July 5 a pretty branch of this valuable plant was shown at the monthly meeting of the Scottish Horticultural Association. The spray was grown and bloomed near Edinburgh with such plants as *Buddleia globosa*, which flowers freely in the district. The spray shown was a foot long and 4 inches across at the base, tapering into a beautifully moulded pyramid of tiny Daisy-like flowers an inch across at the top. It is described by Nicholson as hardy in the south of England, but until the meeting I was not aware it would thrive in the open air so far north as Edinburgh. This

species is said to thrive in almost any soil, and to be readily propagated in summer by means of cuttings made of the half-ripened young wood.—D. T. F.

Abutilon vitifolium.—Mr. S. Arnott's note on the decorative value of large specimens of this Abutilon when grown in the form of tall bushes in sheltered situations should lead those who possess warm gardens in the south-west of England and in Ireland to plant this beautiful subject more freely. As he says, description fails to give an adequate idea of the charming picture presented by such plants when in the zenith of their beauty. There are, I am glad to say, not a few gardens in South Devon where they are thus grown, both the porcelain blue and the white varieties being represented.—S. W. F.

Escallonia langleyensis.—This is a decidedly pretty addition to hybrid shrubs, among which the genus *Escallonia* has not, as far as I am aware, previously figured. It was raised by Messrs. Veitch at their Langley nursery, and obtained from *E. Philippiana* crossed with the pollen of *E. macrantha sanguinea*. The little open bell-shaped flowers are borne in as great profusion and much after the same manner as those of *E. Philippiana*, but instead of being white, as in that kind, they are of a pleasing shade of pink. It received an award of merit last year on June 15, and was recently exhibited in good condition at the Drill Hall.—T.

Philadelphus Lemoinei.—I was certainly surprised that this charming little shrub had not up to the Royal Horticultural Society's meeting on June 28 received any recognition from the floral committee, but on referring to the published lists such proved to be the case. An award of merit was bestowed upon it on that occasion, and but for the fact that it is now well known and generally distributed, it would, I venture to think, have received a first-class certificate. These different hybrid forms of *Philadelphus* obtained by the intercrossing of the little new Mexican *P. microphyllus* with the European *Moek Orange* (*P. coronarius*) are really charming shrubs, remarkable not only from their profusion of bloom, but also for the grace and elegance of a well-developed specimen. One particularly desirable feature possessed by *P. Lemoinei* is that the blossoms have for the most part the agreeable fragrance of *P. microphyllus* rather than the heavy, unpleasant smell of its other parent. There are now several varieties belonging to the *Lemoinei* group, one at least of which (*Boule d'Argent*) has double blossoms.—H. P.

Magnolia pumila.—This species of *Magnolia* is but seldom met with, and certainly, as far as the ornamental qualities of its blossoms are concerned, it has no very strong claims to extended cultivation, but the flowers are so fragrant as to at once attract attention. It is, as suggested by the specific name, quite a small-growing plant—at least for a *Magnolia*—and will flower freely when not more than 18 inches high. The ovate leaves, which are each about 6 inches long, are of a dark glossy green on the upper surface and slightly glaucous beneath. The flowers, which do not expand widely, are about the size of a pigeon's egg and of an ivory-white, tinged with green. The fragrance of this species is even more pronounced during the evening than it is in the daytime. It is a native of Java and was introduced towards the latter part of the last century. It succeeds perfectly in a mixture of loam, peat, and sand in a warm greenhouse or intermediate temperature. This species will strike readily from cuttings of the half-ripened shoots put into sandy soil and kept close till rooted. Plants so obtained flower when quite small, and I have had them when but a few inches high, and in 2½-inch pots each bear a comparatively large globular bloom.—T.

Magnolia Watsoni.—This must certainly be assigned a place among the most desirable shrubs that have been introduced within the last ten years. The flowers, which are freely borne, are nearly 6 inches in diameter, and ivory-white in

colour. A very conspicuous feature of the flower is a broad ring of crimson filaments that surrounds the pistil. When first expanded the flowers are very agreeably scented. This *Magnolia*, though it is as yet but little planted, has proved hardy in this country, at all events in fairly sheltered positions. *Magnolias*, as a rule, do not readily establish themselves, particularly if they are planted in a bleak or exposed spot. All of them succeed best if sheltered from the wind, and a good plan is to plant them when small in a clearing where there is a shelter belt of trees and shrubs sufficient to break the force of the wind, but not near enough to rob the soil or to shade the *Magnolias* to any great extent. A soil that is not too much parched up at any time is also necessary to their well-doing. Another species nearly related to *M. Watsoni* is *M. parviflora*, but the former is the better of the two. There are now so many *Magnolias* that differ widely from each other in stature, flowers, season of blooming, and other particulars, that a most interesting garden feature might be formed of *Magnolias* alone.—H. P.

FLOWER GARDEN.

EXHIBITING TUFTED PANSIES.

THERE is a danger of missing the mark altogether by the encouragement given to the production of florists' flowers such as are met with at exhibitions of the Tufted Pansy, especially where these beautiful hardy flowers are set up in sprays. The exhibitor stages blossoms partaking of all the points of a florist's flower regardless altogether of the plant's habit of growth. It is a fact that many of the finest varieties met with at shows, both in competition and in the exhibits of the trade specialists, are quite unsuited for the flower garden. The question therefore arises, What useful purpose does the present method of exhibiting these flowers serve?

In the first place it must be admitted that a number of sprays, neatly arranged with their own foliage, more especially if a wise selection of varieties be made, is effective, and there is little doubt that many visitors to the shows are captivated by what they see there. This result, most people will readily admit, is satisfactory so far, but the great mistake is made in ordering plants of the handsome kinds exhibited, and which in the succeeding season rarely give the results anticipated. A large number of the sorts, instead of being beautifully tufted and compact in their habit of growth, are coarse, and instead of flowering freely and continuously, are only to be seen in good form during a somewhat limited period, after which the flowers are puny and unsatisfactory. To this rule, however, there are several exceptions, the blossoms being equally valuable for exhibiting as well as for garden decoration, and it is to the raising of such sorts that the enthusiast might well devote more attention.

Beautiful though the last-mentioned class of flowers may be, and greatly admired by the public when arranged in sprays, their excellent qualities for the flower garden can never be properly appreciated until growing plants can be exhibited, showing at once their free-flowering properties and their habit of growth. The type of plant alluded to here is well represented by *Florizel*, a lovely bluish-lilac, wonderfully free flowering on somewhat short, stout footstalks, and of a splendid tufted growth. If the public could only see plants such as this staged growing in pans, baskets, or any suitable receptacle, they would at once be convinced of their great value. There would be no deception if this rule of exhibiting were

carried out, as visitors could see for themselves the class of plant they were ordering, and quickly appreciate their value for certain forms of garden decoration. The craving by exhibitors after the formal flowers of the florist checks all progress, and the sooner less regard is paid to this and more attention given to the raising of pretty free-flowering varieties, combined with the essential of a good habit, the better it will be. At the present time, as with other flowers, owing to the orthodox system of exhibiting the Tufted Pansies, there are many very beautiful medium-sized flowers which are rarely, if ever, seen, and among these are some of the most valuable of our garden plants. Then, too, the rayless miniature sorts, the progeny of the sweet-scented *Violetta*, could not very well fail to interest many gardeners, and a few two-year-old clumps of such sorts in full flower are among the prettiest and daintiest things imaginable. If some of our specialists would only lead the way in this direction, there is good reason for believing that an impetus would be given to the cultivation of the best sorts, and many flower gardens be considerably benefited. Raisers of these flowers, too, would feel there was some scope for their efforts, and would be stimulated in their endeavour to introduce novelties of the best, as for some time past, plants of the loveliest description, but developing blossoms somewhat under the recognised standard of size for arranging in sprays have been discarded, or else retained solely in the raisers' own gardens. D. B. CRANE.

Campanula celtidifolia, which I received a few years ago from Mr. Carrington Ley, is conspicuous in the border with its large clusters of bright blue flowers. It is perfectly hardy and easily propagated by division. This genus is so very extensive that it is a boon sometimes to have one of special merit brought under one's notice.—D.

Lilium Lowi.—I have just flowered a bulb of this beautiful and very variable species. It is a native of Upper Burma and is said to be perfectly hardy; the colour is white, spotted with violet in the inside of the bell-shaped tube. Some of the plants have pendent and others erect flowers. Mine are pendent, and so much so that one has to lift the bloom to see the interior. It is too scarce as yet to trust it in the open ground, and mine has, therefore, flowered in a pot.—D.

Lilium Henryi.—Certainly for vigour of constitution there is no Lily that can compare with this. My bulb of it now bears a flowering stem upwards of 6 feet high, and I hope by-and-by will be a grand sight. It has been truly described as an orange-yellow specimen, and it does not seem to care whether the season is dry or wet, cold or mild. In a few years it will doubtless be more plentiful, and will occupy a conspicuous place in all Lily borders.—DELTA.

Eryngium Oliverianum.—This is one of the prettiest Sea Hollies I have seen, and is in good condition on the herbaceous border at Livermere Park, where the light sandy soil apparently suits it well. Here on a much heavier soil the *Eryngiums* are only a partial success, *E. amethystinum* being the best grower. The plant above named has the segments of the flower very beautifully cut and frimbriated; it opens a very pale greyish-blue, but when fully developed is of a lovely tint. It makes a fine show and should become very popular.—D.

Hardy plants.—This has been a very trying season for gardening generally, and herbaceous borders have amongst other things suffered from the long spell of dry weather. Some gardens are abundantly supplied with water, while in many districts it is a luxury. The effect has been seen in the disappearance of some plants and in the dwarf character of others, while some seem to have done especially well. I have never, for instance, had *Lilium testaceum* so tall and full of flower, but I see a manifest deterioration in some of the clumps of the specimen varieties. The

plants in the rock garden have on the whole done well, and even now there is a considerable amount of bloom.—D.

CROCUS IMPERATI AND CROCUS VERNUS.

IN gardening books the Crocus used to be called "the harbinger of spring," but the many kinds of Crocus now in cultivation have various seasons of flowering, so that they may be said to last for eight months in the year; in fact, in Edge Garden *Crocus vallicola*, the earliest of the autumn kinds, comes out in August, and

Crocus vernus leucorrhynchus. Engraved for THE GARDEN from a photograph sent by Miss C. Wolley-Dod.

spring Crocuses last into March. *C. Imperati*, which is here figured, may be called a link between autumn and spring kinds, flowering generally in midwinter. After a wet and warm autumn, such as the autumn of 1897, several were out before Christmas, and they arrived at their best before the end of January, which was unusually dry and fine. February, however, is generally their best month, and, of course, in a climate like that of the midland counties of England winter flowers must take their chance, and take advantage of any fine interval frost and storms afford them. *C. Imperati* is named after a naturalist of Naples, Imperato, who lived in the seventeenth century. The species is local, being found only in those parts of Italy which are within about 100 miles of Naples, north and south. It is a very beautiful species, the outside of the flower being pale fawn colour, striped with brown, and the inside rich purple. When the sun is bright the flowers open very widely, as represented in this engraving. The shades of colour vary much. Maw, in his monograph of the genus *Crocus*, gives a coloured portrait of several varieties. The most distinct varieties which I have come into bloom later than the ordinary type, having the outside of the flower without stripes, and the inside very deep rich purple. It also has the tube much shorter, the expanded flower lying nearly flat upon the ground. There is an albino variety, but the flowers are not very pure white and it is somewhat more delicate than the type, the bulbs often dying when they ought to be renewing themselves. This variety comes tolerably true from seed, but as it is rather late flowering, it is not of more value, except as a rarity, than some of the pure white forms of *Crocus vernus*. A fine mass of *C. Imperati* in February is a sight to encourage, and it is worth while using bell-

glasses to protect the flowers from snow and bad weather.

Crocus vernus has a wide native range in the south of Europe, extending from the Pyrenees to the Carpathian Mountains and nearly through Italy to the south. It is included in the flora of the British Islands, but only as a naturalised foreigner. In my boyhood I lived near Nottingham, and I recollect nearly seventy years ago what a sight the purple Crocus used to be there in early spring. Driving into Nottingham by the Derby road on a clear day in March, and looking down across what was then open park attached to the castle, the meadows below seemed to me to be covered by sheets of water reflecting the blue sky, such was the abundance of purple *Crocus vernus* extending over many acres; but the Midland railway station and sidings, as well as new streets, now cover what was then a clear area for flowers. Later in the year an autumn Crocus, *C. nudiflorus*, was nearly as plentiful in different parts of the same meadows, reaching to the Trent side where Wilford Ferry then was. The variety of *Crocus vernus* in the accompanying engraving is one figured in Mr. Maw's monograph (plate 26) under the name of *leucorrhynchus*, called also Pheasant's Feather. It is purplish white, feathered near the tip with bright purple, but, as the name implies, having the extreme top of the petals pure white. I have cultivated this

Crocus Imperati at Edge Hall. From a photograph sent by Miss C. Wolley-Dod.

variety for many years, and find that these very marked characters are reproduced in the seedlings. It is one of the earliest of the varieties of *C. vernus*. C. WOLLEY-DOD.

Edge Hall, Malpas.

Ostrowskia magnifica.—I have grown a few plants of this. This year they have flowered with me; one of the plants has given pure white blossoms and the other light shades of mauve. In a letter just received from Mr. Fremlin, in whose garden this plant does so well, he tells me that white-flowered seedlings are not uncommon, and his plants are doing well. There is no doubt that it well deserves its specific name of *magnifica*, for it is the grandest of all Campanulas or allied plants. The flowers are fully 6 inches across and very stout in substance. It seems to be perfectly hardy, coming as it does from Turkestan and other parts of Central Asia. There is no doubt that it will find a place when better known in all gardens where hardy perennials are cultivated.—DELTA.

Epilobium angustifolium.—In Hyde Park good use is made of our own native Willow Herb (*Epilobium angustifolium*), with which one large circular bed is completely filled, thus forming quite a dense mass of stems, crowned with

myriads of its pretty blossoms. Associated with other plants it is of far too aggressive a nature to prove an agreeable neighbour; hence it should be planted with care, but with an entire bed given up to it, as in Hyde Park, no objection can be taken on that score. The soil, too, being fairly dry, it reaches a height only of 4 feet or 5 feet. For the last two or three years this particular bed has been most striking, and attracted a larger share of attention than many of those filled with tender exotics, which need protection during the greater part of the year.—T.

NOTES ON THE EARLY SAXIFRAGES.

No group of alpine is calculated to create a more widespread interest than the many beautiful species and varieties of early-flowering Saxifrages. I refer more directly to the crested section and to other beautiful kinds, such as *Bursleriana* and the like. Beautiful and interesting as these early kinds undoubtedly are, many of them are by no means of easy culture, or, at least, this sort of impression gains ground because anything like large examples of them are rarely if ever seen. Of course, among the trade growers examples of extraordinary size are not to be expected, simply because the slow-growing character of the plants on the one hand with the demand on the other prevents the retaining of plants for specimen size. In a large number of instances progress is very slow, but in others, as, *e.g.*, *S. apiculata*, *S. sancta* and a few others, progress is quite rapid, and of these a lovely carpet may be formed in two or three years if the proper position be selected. It is quite a different matter with such diminutive gems as *aretioides primulina*, *Boydii*, *Boydii alba*, *Bursleriana* and its varieties, *calyciflora*, *squarrosa*, *diapensoides* and others near akin. Of these, all of which are either slow growers, or comparatively so, the well-known *Bursleriana* is the freest grower, though oftentimes rather disappointing just when success would appear in sight. Frequently the beautiful silvery grey tufts of this kind become patchy and disfigured during winter from a cause I cannot explain, but which is as prevalent when the plants are placed in frames for the winter as when wintered in the open. Once or twice lately I have seen tufts of large size similarly affected, wherein rosettes each one and a half inches across have been destroyed. Singularly enough, a solitary tuft may be thus affected in perhaps two or three places, not necessarily so large as the above, but large enough to create disfigurement all the same. All the forms of *S. Bursleriana* at times are subject to this attack, the older plants as a rule being more liable to it. The only other species I recall suffering in the same or similar way is the spiny-tufted *S. juniperifolia*. In some winters this species is very badly attacked, the past mild winter being no exception, some very large patches being now greatly disfigured. This kind, however, quickly recovers if taken in hand early in the year, the brown portions pulled or cut away and repotted closely and firmly up to the green portion again. The *Bursleriana* forms do not so quickly recover, and these also require considerably more care in dividing than the other species just mentioned. At the same time I am convinced that the tufts of this species are not divided sufficiently often to ensure continued health and vigour in many instances. Indeed, it is no unusual thing for a plant of this to be one year covered with flower buds and the next season to be almost barren. My theory is that the rosettes of flowering size all performed this function in the one season, and perished as a result of that flowering, the remaining rosettes composing the tuft being too small and too crowded to attain to flowering size in the year following. This, however, is most likely to ensue with pot-grown plants rather than with plants possessing greater freedom in the open rock garden.

What I suggest as a remedy for this flowerless condition is that the plants should be divided immediately after flowering, unless seeds are

required. A good way to divide *S. Burseriana* or its varieties is to wash away all soil in a vessel of water, and, with the root fibres in view, carefully pull to pieces, cutting away any disfigured portions afterwards. Cuttings of this kind root quite freely in pure sand kept moist, and though the process is a slow one it is quicker than raising by seeds. By the latter means, however, quite a numerous progeny may be raised with care, which latter is essential always, more particularly as the seedlings are appearing. Seeds of these should be sown as soon as ripe, but not covered with soil, a piece of darkened glass being sufficient. Well drain the pots, nearly fill with gritty loam made firm, and well soak before thinly scattering the seeds. Place a saucer containing water beneath each pot, and sustain moisture by this means or by plunging in water two-thirds the depth of the pot from the time of sowing. These remarks on seed-sowing may be followed throughout, and if carefully pursued some nice stocks of the choicest gems this race contains may be added to the collection. Of *S. Burseriana* it is scarcely possible to possess too many, and by filling some large pans a lovely display of this may be obtained. Permanent patches of this on rockwork are benefited by a free mulch of sand and soil each year when not divided, by way of imitating the abundance of grit annually washed into the tufts in their native habitats.

The lovely *S. Boydi* and *S. B. alba* are in their requirements almost identical with the beautiful species above named, though slower in growth and possibly more difficult to cultivate in English lowland gardens. Of their worth and beauty, however, there need be no two opinions, while in point of excellence the flowers are not surpassed by those of any kind at present in cultivation. Both kinds are deserving of the greatest care and attention, and when in flower repay it. It is, however, possible to improve even these lovely kinds by a more free spreading habit of growth, for the flowers of each would be very difficult indeed to improve upon, particularly in form of petal or substance. It is, however, no easy matter to cross-fertilise these early kinds unless the matter has been well thought out and the flowering anticipated. To cross-fertilise any kind with the early-flowering *S. Burseriana*, for example, would mean that this species would require retarding or another kind forwarding to meet the case. But any attempt at forwarding such things should be made a matter of time and very gradually done, otherwise a weakly flowering may result. Again, where hybridising is thought of the best results will be secured later on when greater sunlight prevails. Another lovely kind and by no means plentiful is the pretty free-flowering *S. aretioides* *primulina*, a hybrid raised, I believe, by the late Mr. James Atkins in his famous hardy plant garden at Painswick. This garden, small though it was, was literally crowded with the choicest plants, and among them hosts of the most beautiful of the Saxifrages. The above variety of *S. aretioides*, with its pretty yellow flowers, is among the most profuse flowering and quite easy to manage, though naturally, like the type, very slow in growth. A solitary tuft of this forms a perfect half-circular mound, and attracts frequently even when not in flower by its symmetrical form. In the matter of soil, I treat this, in common with many other kinds, to richer soils than many growers of these beautiful alpines, and not only in respect to its quality, but also in quantity, with more than usual liberality. Too frequently such things are virtually starved by being long kept in a 2½-inch or a 3-inch pot, which with requisite drainage and the small stones usually added to the soil, leaves all too little of the latter for the host of root fibres present in a good tuft of one of these plants. Even a cutting of, say, *S. Burseriana* which is not more than a quarter of an inch high will in pure sandy grit send down root fibres from 4 inches to 6 inches long in the course of three or four months, while growth or progress above ground has been of the most meagre description. And if we assume that such roots are in anything

like a similar proportion in a large plant, it will be seen that the scrap of soil usually given in pots is all too limited. The soil I generally use for the small kinds referred to is about three parts loam, and to this is added very old and short manure finely sifted—the manure already of a crumbling nature—with sand and old mortar or broken brick rubbish.

Very firm potting I regard as one of the essentials to success, and I consider it equally necessary to closely gather the tuft in the fingers of the left hand before placing in the soil. Many Saxifrages root freely from the stems directly below the rosettes of leaves, the more so where the soil is near at hand. By thus collecting the rosettes in a cluster as it were, a tuft may be formed of a previously ragged, spreading plant, though such is not likely to ensue with any of the dense-growing kinds as *S. squarrosa* or *S. aretioides*, &c. During summer it is a good plan to gather together the pot-grown examples of these Saxifrages to a little shade, where also they may receive frequent copious waterings overhead. Indeed it is surprising how they thrive with this abundant summer watering, and, if in good soil also, the result will be even more marked. Where a collection of such things is grown, a sand bed for plunging the pots to the rim is excellent, and this, with frequent watering overhead, will greatly assist growth, provided all overhead covering be discarded. Many of the choicest kinds do admirably thus treated, and those lovely white kinds, *S. Rocheliana* and its variety *coriophylla*, form really beautiful patches if grown in this free and generous manner.

Hampton Hill.

E. JENKINS.

TUFTED PANSIES AT TRENT PARK.

THE value of these useful plants has been fully recognised at Trent Park this season. A recently constructed terrace-garden with a north-western aspect was looking at its best with a bright display of many excellent subjects, but none were more pronounced in their effect than the pleasing varieties of Tufted Pansies which Mr. Lees has employed for the purpose. These were not planted out in long narrow lines, but in masses in triangular form, and most artistically disposed in regard to the association of colours. As viewed from the upper terrace this arrangement was pleasing. As the plants appeared to be thriving so well in this position, it may be interesting to mention the varieties which were best represented. A very pretty mass was *William Niel*, which was flowering profusely; a short distance removed was a dark velvety blue-black sort named *Isa Ferguson*. *Princess Louise* here proved its value as a grand yellow, in most cases represented by rayless blossoms, with short stems on a charming compact habit of growth. *Rosea pallida*, too, with its pale blush blossoms made an effective display. Some growers consider this variety washy in colour, but here it was constant and of a particularly pleasing shade. A fine bold mass of *Duchess of Fife* was much admired. This was a striking proof of the lack of effect which some of the margined flowers give when massed when compared with the selfs under the same conditions. Another fancy flower was *Sunset*, a soft yellow, with a rich orange eye, but with crimson upper petals. This has a nice habit of growth. To those who know the old variety *Countess of Kintore* it may be interesting to learn there is a much handsomer variety with similar markings to that sort and named *Mrs. C. F. Gordon*. This plant produces quite freely much larger flowers than its prototype, and the habit is all that can be desired. A grand batch of a variety named *Bella* was much admired. The flowers are large, rayless, and have long footstalks. The lower petals are white, the upper ones shaded pale blue. *Ardwell Gem*, the freest of the sulphur yellows; *Ethel Hancock*, the purest of the whites, and many others each assisted to make a charming display.

D. B. C.

NOTES ON HARDY PLANTS.

Gunnera monoica is a pigmy of the genus. The leaves are almost round and crenate; the florescence has the effect of pale Sphagnum nestling among the short leaf-stalks. The whole plant is scarcely 2 inches high. It may be employed as a creeper for the moist nooks of rock-work, and a mixture of live chopped Sphagnum in loam and leaf-mould, forming a spongy compost, seems to suit it.

Silene acaulis grandiflora.—The third name most fittingly represents a special feature, which renders it superior to the type. The original plant was said to have been found wild on the Glyder, N. Wales. The flowers are of a rich deep colour, larger than those of its parent. It is less liable to turn into black patches, and in all ways more amenable to garden uses than the type.

Malvastrum lateritium, or *Malva lateritia* of Hooker, has flowers each 1½ inches across of a pleasing shade of cinnabar-red, with a densely tasselled mass of orange-yellow anthers. The perfume resembles that of a newly crushed Peach. Being an Uruguay species, its cultivation in our climate will need to be special in the way of winter protection, but it is certainly worth all this and more, as it is only the strong specimens that can do the species justice.

Meum athamanticum.—As we learn the uses and better features of our plants—and many of them, perhaps, very common plants—we shall come to admire this for its charming foliage, which from March to October is ever changing its colour. Just now the sunnier side of the specimen has the richest effect from a blend of sombre green, finely-cut, Fennel-like leaves, touched off with purplish brown, mahogany, and bronzy yellow. The early March herbage is the palest apple-green, getting deeper as the summer advances. I ought to say that the colour results of the foliage are not of these pleasing kinds unless you take off all the flower-stems as they push—the whole stem whilst young—and, of course, these (the flowers) are of no garden value, being but of the plainest type of an umbellifer. The strong smell of the leaves, of course, has to be taken into account when one picks them for indoor use. The scent in this case is liked by many; by others I know it is considered too strong. Anyhow, the smell is not given off only by contact, and so you may enjoy all the rich leaf tints on the plant as a purely garden object without the strong aniseed scent.

Veronica lycopodioides.—It may be as well to say a word more on the question of the name, because I believe I have since in the Botanic Gardens, Edinburgh, seen the plant under another name, and I asked if the second name would be sure to prove the more correct one, and was answered that nothing could yet be certain about these dwarf New Zealand species, being at that time only just introduced. I said I would stick to the first name until we got a well authorised change and have done so. I have met with nothing since to show me that my plant is wrongly named, or if it is, that it is only wrong in common with others. The present kind is now blooming beautifully, hence this note, because this and others of the Whipcord section rarely flower. This plant is scarcely a Whipcord kind; the leaves are just showing a rudimentary effort to attain the more common form of a leaf, hence the appropriateness of the name *lycopodioides*. The flowers in this case are charming. They are small, starchy, of the purest white, with black anthers, being compacted in clusters of four to eight flowers. This form of blossom bedecking the sombre and dense little bushes of but 4 inches or 5 inches high, as may be readily imagined, is just the sort of material for the rock garden. One can scarcely plant these pigmy shrubs wrong; in dry or moist soil they thrive, and, provided they are not deprived of sunshine, may favour us after mild winters with some flowers. I personally never count on flowers, as the peculiar and

pleasing form and habit of the plants are highly decorative without bloom.

Woodrille, Kirkstall.

J. Wood.

NOTES AND QUESTIONS.—FLOWER.

Pelargonium Eleanor.—This zonal Pelargonium is of good dwarf habit and free flowering, while the blossoms are of a kind of orange-vermillion tint, a peculiarly bright and effective shade of colour. It is a very good variety either for pots or outdoors.—H. P.

Lilium Browni.—I have been very successful in the cultivation of this beautiful Lily this year. On no less than four of my plants there have been three blooms on one stalk. As I have neither seen nor heard of more than two before, I write to ask you if you can tell me whether three is very exceptional or not.—J. B. M. CAMM, Bournemouth.

Lythrum roseum.—A large bed of this richly-coloured variety of the native purple Loosestrife (Lythrum Salicaria) is particularly effective just now in Hyde Park. It forms quite a close mass, bristling with flower-spikes, the blossoms on which are rather later in opening than those of Epilobium angustifolium, a large circular bed of which is in close proximity thereto.—H. P.

Codonopsis ovata is a somewhat curious and pretty bell-shaped flower from the Himalayas. The flowers are prettily marked, the outside having a slight metallic blue lustre, and the inside veined and blotched with white and yellow. I received this plant under the name of Codonopsis ovata, but do not find the name in Nicholson's "Dictionary of Gardening," but I hear from Kew this is the correct name. The plant grows about 1 foot high and is apparently very free flowering. Unfortunately, it has an unpleasant odour, the stalks especially emitting it.—D.

AN ADDRESS TO GARDENERS.*

It is the natural taste, the secret relationship between man and a corner of earth more especially appropriated, enclosed, cultivated, sown, watered, harvested by the hands of the gardener, which have made of the history of gardens in all ages and in all countries a part of the very history of nations, and also a part of the dreams of future life or of popular theologies. Study all these theogonies, all these religions, all these histories, all these fables, not one of them but makes man begin in an Eden, that is to say, a garden; not one but makes him finish after death in an Elysium; not one but mingles that image of a garden, abounding in waters and fruits, with the images and reveries of primitive or future felicity in heaven. What does that prove? That human imagination, in all the paradises it has created for itself, has not been able, to dream of anything better than an earthly or heavenly garden; waters, shade, flowers, fruits, lawns, trees, a fair sky, serene stars, fertile land, a secret intelligence, a mutual friendship, as it were, between man and soil; so true it is, too, that in his fairest dreams man has not been able to invent anything better than Nature: a place in the sunlight, sheltered from trespassers, made beautiful by vegetation, enlivened by the birds of the sky and animals, friends of man, sanctified by the labour of the hands, made divine by the felt presence of the Creator, inhabited, finally, by the family, love, friendship, and by a succession of eternal generations! It is there humanity has placed happiness; and is it not there, too, that you persist in seeking it? In seeking it, not unchangeable and complete as in our dreams, but seeking it at least in the imperfect and brief images, in which we have been permitted to have a glimpse of it now and then for an instant, here below. You do well to seek it there, for if your occupation is the happiest of occupations, your science is at the bottom the least chimerical, the least problematic, the least deceptive, the surest of all sciences.

Yes, independently of the other considerations, which ought to unite the gardener with his art, there is one which has often occurred to me, and which must far more often have occurred to your-

selves: that of all the arts, of all the sciences, I mean, your science is still the one which most truly deserves this name, which the least deceives him who surrenders himself to it, which least distracts the mind in the chimeras of systems, and which in its application restores him most directly and most forcibly to truth. And why so? It is because in your science you are ever in direct touch with, you lay your finger upon, Nature and its visible, palpable, mysterious, but evident laws. Now the divine law of vegetation does not bend to your vain caprices. God, in his immovable works, does not lend Himself to our chimeras. Nature has no indulgence for our false systems. She is sovereign, absolute like her Author; she resists our foolish experiments; she dispels, and sometimes roughly, our illusions. She seconds, aids, rewards us if we handle her fairly and if we work in her true direction; but if we deceive ourselves, if we try to do her violence, to fetter her, to falsify her, she at once violently contradicts us in her acts by sterility, by decay, by the death of all we have tried to create in spite of her and in disregard of her laws. We may deceive ourselves with impunity and for several centuries in succession as to history, philosophy, religious or social systems, even astronomy; we can invent the most absurd chimeras in all these and long foist them on the world for truths. Cultivators of fields and gardens cannot do this. Your longest mistakes cannot endure beyond one season, the period of one vegetation, a spring, a year at the outside. That is the limit of your errors, for that is the limit of your experiments. Beyond this term Nature herself sets you right. She reveals her will to you, for you to harmonise your own work with it. You question her thus unceasingly, respectfully, experimentally, and she answers you always accurately and always speedily. You register your answers in your memories, in your books, in your manuals; and out of this incessant dialogue between questioning man and answering Nature, you compose those catechisms of agriculture or gardening which become the science of vegetation. Thus in elementary books, in the agricultural congresses of the kind you are founding here, this science is propagated, enlightened, extended. Thus it has been since Pliny made the catalogue of all the plants of the Roman Empire in his day; since Charlemagne himself pointed out in his Capitularies, which were his Charta, the name and number of the vegetables which he commanded to be cultivated in his gardens; since Cato, the most inflexible statesman, imposed upon each Roman citizen, however poor, the duty of cultivating flowers in his enclosure, that his culture and elegance might also impart some culture and elegance to the manners of the people (for in desiring to repress the excessive luxury of the republic he did not at any rate desire to impose a sumptuary law upon vegetation), until the time of those maritime and horticultural expeditions of the Crusaders, of the Dutch, of the English, to seek and gather in from the ends of the earth, one by one, those ninety-eight leguminous plants, or those flowers with which your present kitchen gardens and your flower-pots are this day enamelled; the art of gardening, first sketched out by the Romans, universalised and brought to a prodigious state of perfection in China, enlarged in England to the proportions of an aristocratic luxury, depreciated and strained in Holland to the point of adoration of the Tulip, raised in Italy to the dignity of a splendid art, in association with statuary, sculpture, and architecture, utilised in France by its alliance with high agriculture of which it is the enlightener—at last, thanks to your efforts, reaches in several parts of Europe the condition of an industry, employing millions of hands, and importing and exporting millions of fruits and flowers. Thus, observe, for the first time, gardening, which was hitherto a recreation, a domestic luxury, a decoration of the earth, is becoming a new and magnificent subject of commerce at a time when work fails man rather than man work, at a time when the notion of an industry is the invention of a source of wealth, is the invention of an occupa-

tion, of a salary, of a livelihood for thousands of workmen.

And do not think that is an exaggeration. I have just arrived from the South. I have seen upon the littoral of the Mediterranean a considerable coasting trade of flowers. Tuscany and the State of Genoa cultivate and export to the value of several millions the produce of their flower beds! But one art has begotten another. After the art of their cultivation has come the art of harvesting, assorting flowers, colours, shades, scents. This art has made such progress at Genoa, for instance, to such an extent have Roses, Carnations, Dahlias, Tulips, Ranunculus been studied, combined interwoven, plaited, that bouquets intended for the table at festivities, often more than a yard in circumference, resemble Smyrna carpets, vegetable fabrics, perfumed velvets, mosaics of vegetation. Veritable weavers weave these perfumed tissues. The bouquet-makers there, as at Athens, form a profession by themselves. The bouquets you admire at the fêtes of Toulon, Marseilles, Bordeaux, even Paris, have often been woven at Florence or Genoa. Thus luxurious gardening becomes more and more an industry. Go on perfecting it, and it will become a new art, a painting of which the palette will be a garden. But whatever the merit of this industrial garden in the eyes of the economist, let us be frank and to the point. This is not the principal and the eternal attraction of gardening. No; what has in all ages fascinated men in this fine art, and especially the most sensitive, studious, lettered men, poets, sages, writers, philosophers, even statesmen and warriors, is the closer communion with Nature, the charm yielded by the study of her phenomena, that pious contemplation of vegetation, those ecstasies endlessly renewed at the sight of this universal life, of this dumb intelligence diffused over and visible in the vegetable creation; these vague boundaries between the animal and vegetable kingdoms, which seem to unite all the organised elements into one mysterious unity athwart their apparent differences and divisions. It is this conviction of the divinity of Nature which has often made me accuse myself of pantheism. I am not a pantheist. No, I am not like the child who, seeing a face reflected in the glass, thinks the face and the glass are but one, and stretches out its hands to seize the image. Nature in my eyes, as in yours, is only the immense infinite luminous mirror in which its Creator is reflected. These are the seductions which have in all ages drawn the souls of thinkers to the spectacle of germination, flowering, and fructification in gardens. Shall I quote you Pythagoras, who enjoined upon his disciples, as a maxim of wisdom, to adore the echo in rural spots? Scipio at Linternum? Diocletian renouncing the sovereignty of the world to go and cultivate his Lettuces? Horace at Tibur? Cicero at Tusculum or under his Orange trees at Gaëta? Pliny, describing for posterity the plan of his alleys "framed in Box," and giving the catalogue of his trees shaped into vegetable statues? Old Homer, recalling, no doubt, his own paternal enclosure, in the description of the little plot of Laërtes, shaded and enriched by his "thirteen Pear trees?" Petrarch at Vaucluse or on his hill of Arqua? Theocritus under his Sicilian Chestnut trees? Gessner beneath his Zurich Pines? Madame de Sévigné, in her garden of the Rochers or in her park of Livry, immortalising her gardener in the touching phrase of one of her letters, which is as good as a mausoleum to him: "Master Paul, my gardener, is dead; my trees are saddened by his loss!" And closer to us, Montesquieu, in the broad alleys of his château of La Brède,* evoking the shades of empires and the spirits of legislators, like

* His latest biographer, M. Albert Sorel, writes of the great legist: "He returned to La Brède after more than three years' absence (of travels over Europe), rejoined his family, devoted himself to his affairs, cultivated his Vines, drew up his genealogy, and transformed his park into an English garden."—A. F. S.

* Translated from the French of Alphonse de Lamartine by Albert Forbes Sieveking.

Macchiavelli, before him, and greater than him in his rustic hermitage of San Miniato, on the hills of Tuscany? Voltaire, in turn, at the "Delices" or at Ferney, framing Lake Lemano and the Italian Alps in the horizon of his gardens? Buffon, at Montbard, like P'ny at Rome, skilled to enjoy in the magnificent living museums of his park the splendours of Nature, which he described? Lastly, Rousseau, whom I had almost forgotten, who desired that his ashes should rest under a Poplar on an island in the centre of a last garden?*

Ah! that man, born of a working class, and almost educated in a servile class, doubtless felt more closely than another the retreat, the consolations of solitude. How often in my first youth, in the first fervour of the imagination and of the soul for great names and sensitive genius; how often have I visited alone, or in the company of a friend whom I have lost on the road, his dear Charmettes, that little house, that narrow garden, hidden in a ravine rather than in a valley, of the hills of Chambréry, but in the shadow of the beautiful Chestnuts of Savoy! How many hours, how many whole days have I not passed under the little creeper-clad arbour which he loved, dreaming of him, reviving his life, looking at the evening rays filtering through the Vine leaves yellowed by autumn, as though still seeking there the most sensitive and most eloquent contemplator of Nature, of the vegetation of God! It should never end if I tried to quote to you all the famous men who have stamped their memory upon gardens. In truth we could re-write the history of all great minds by that of the rural retreats which they have inhabited, loved, or made famous by their steps: to such a degree is man mingled with the earth, either in the cradle, during life, or at the grave of its possessor. And so far does Nature resume her place in the very existences which appear most remote from her, and most estranged from the simple and pure delights of the soil and its cultivator.

And believe me these delights are not reserved for the great ones of the earth, for the rich possessors of parks. No; there is no need of walks of magnificence, of vast spaces, to enjoy all the happiness God has hidden in the culture or the spectacle of vegetation. There are pleasures that fortune may not appropriate or monopolise to itself alone. Nature is never aristocratic, in the sense at least that she has given powers for the enjoyment of natural pleasures, to the rich different from the poor, to the man of leisure different from the man of labour. Whatever the size of the space man dedicates to his enjoyments, there enters into his soul through the senses exactly the same measure of sensations and of pleasures. The human soul is thus constituted because it is infinite. The human soul is endowed with such a power of compression or extension, it is endowed with such elasticity, with such a faculty of contraction or expansion, that it may overflow the universe too narrow to contain it, and cry out, like Alexander, for more worlds: or it may concentrate, fold itself, contain itself entirely in an imperceptible point of space, and cry out, like the sage of Tibur, from the bottom of his half-acre sown with Mallows and watered with a tiny stream, "This small corner of the earth is worth all the world to me."

You may be certain that there was as much pleasure, as much intensity of enjoyment, of sensibility, of contemplation, of tenderness in the soul of Rousseau gazing at the sunset behind the Vine of the little plot at the Charmettes as in the soul of Buffon watching the day break above the Cedars in his park of Montbard. You may be sure that the possessor of thousands of acres planted, laid out, irrigated into gardens on the hills of England, Scotland, or the environs of

* Rousseau was buried on the Isle of Poplars in the garden of Ermenonville, designed by his friend and last host, the Marquis de Girardin. The latter was the author of a work on the "Composition of Landscapes," translated by Malthus, which ranks high in the literature of landscape gardening.—A.F.S.

Paris does not own a feeling more delicious, more overflowing, more pious towards Nature than you when you rest on Sunday in your little plot of Hawthorn, or at the foot of a few trees in blossom that you have grafted near your two or three hives humming in the sun, by the side of the bed where you have laid down the spade you will pick up to-morrow. And who can better experience this than I? For if you knew Latin as well as you know the universal language of vegetation, I could cry out in your midst, like Virgil's shepherd, *Et in Arcadia Ego!* "I, too, have been a gardener!" Yes, I, too, have had as my first cradle a little rustic garden, hemmed in by a wall of unmortared stones, upon one of these parched and sombre hills which you see from here to the limits of your horizon; there were to be found (for the mere than modest mediocrity of my father's fortune did not allow it) neither vast tracts, nor majestic shade, nor gushing waters, nor rare flowers, nor precious fruits, nor costly plants; a few narrow alleys strewn with red sand, edged with wild Carnations, Violets and Primroses, and bordering plots of vegetables for the nurture of the family. Well, there, and not in the gardens of Italy or of the great proprietors of the parks of France, Germany, or England, I have experienced the first and most poignant delights that it is given to Nature to inspire in a soul, in a child's or youth's imagination. I dwell now in gardens vaster and more artistically planted but I have kept my predilection for that one. I keep it as a precious possession, in its ancient poverty of shade, water, flowers, and fruits; and when I have a few rare hours of liberty and solitude snatched from public affairs or labours of the mind to give to vague self-communings, it is to this garden I go to spend them. Forgive me these intimate details, these allusions to domestic life. They are not out of place here; we are all fellow citizens, all friends, all of the same flesh and blood. Let us for a moment have but one soul, as we have but one country. Yes, in this poor enclosure, long since deserted, emptied by death; in these alleys overrun by weeds, by Moss, and the Pinks from the beds, under these old trunks drained of sap, but not of souvenirs—on this unraked sand my eye still seeks the footprints of my mother, of my sisters, old friends, old servants of the family, and I go and sit under the fence opposite the house, which is buried year by year deeper under the Ivy, by the rays of the setting sun to the hum of insects, the sound of the lizards of the old wall, whom I seem to recognise as old garden guests, and to whom it seems I might gossip about old times. Just these first joys of man entering upon life, these first habits, these first raptures of contemplation, these early emotions of life in this rustic and solitary spot, in this domestic hearth, now cold and extinct, gave me this early predilection for gardens, and the simple and intelligent men who cultivate them which brings me back so naturally and so deliciously to this annual intercourse in your midst. The spade, the pruning hook, the rake, the watering-pot, the mere flower-pot in the window of the poor workman are inseparable in my heart from these remembrances of my young existence in the country amidst the labours and occupations of a country house and a modest garden. Forgive me, then, for speaking to you about them from my ignorance. You are gardeners by the hand, by science, by study, by practice. I am only a gardener in heart and sympathy. And now let us go, each to our own calling. Go you, encouraged by this competition of your fellow-citizens, by this unanimous interest, which is witnessed by the crowd filling this theatre fuller than at any representation of a fictive art, by this heartfelt share which women take by their presence at your institution; go and cultivate these flowers, those fruits, those vegetables, those marvels of scientific culture in your rows, in your greenhouses, in your open-air laboratories. I, for my part, return to cultivate in this old neglected garden of my fathers, of which I spoke to you just now, what we poor labourers of the mind

cultivate, and, often as wearied as yourselves, study letters, books, philosophy, history, politics, the art of governing men, of improving society, of sweetening the lot of the people, to carry to civilisation and liberty riper and more perfect fruit. But I return there to cultivate especially those images of things and persons loved and lost, those memories of vanished affections, those living, often bleeding, traces of a life already half spent. I hesitate, I hesitate—shall I go further? There is a shame in all deep feeling: we must not withdraw the last veils from the human soul; there are tears which should only fall in silence and the secret of the heart. I go then, I was saying, to find again in that asylum of my childhood charms more powerful for me, for us all than the richest, the most odorous blossoms of our exhibitions—the perfume of memories, the scent of the past, even the pleasures of that melancholy which is the autumnal flower of human life—all things which are to us, so to speak, the emanations of earth, a distant perfume, as it were, a fore-taste of those Elysiums, those Edens, those eternal gardens, where we all hope to find again in happiness those whom we have loved and lost in tears. All things which cause a man of Nature, at whatever distance, in whatever abyss, or at whatever height fortune may have cast him, to desire to return and end his days on the soil which has witnessed his birth, and at least to find his grave in the garden which held his cradle.

GARDEN FLORA.

PLATE 1181.

TRITONIAS.

(WITH A COLOURED PLATE OF TRITONIA CROCATA.*)

For effective grouping in the garden in the early summer months it would, perhaps, be difficult to name anything so beautiful and at the same time so useful as these. This is undoubtedly due as much to their grace and beauty as to their ease of culture or hardiness when properly treated. I purposely use this qualification because it is only rarely that good established masses of them are to be seen. Still less frequently are they grown in pots, while the various species and varieties of which the genus is composed are especially well suited to both these uses. By far their greatest worth, however, is in the garden, where in good soil they not only flower freely, but increase with wonderful rapidity at the root. This is especially true of them when planted in fairly light and well-drained, though well-enriched, soil, the plants spreading out into large patches that surprise many who grow such things for the first time. In short, in the majority of rich light loamy soils Tritonias give but little trouble. In some clay soils where the drainage is less under control these plants in a year or two are apt to fail, and here may be treated differently, mainly, however, by lifting them each year or even every second year and allowing them to remain out of the soil during the winter. In badly drained soils it is best perhaps to raise the bed by an addition of soil of a lighter nature than to undertake its improvement at the original level. By raising the bed the drainage is at once secured, while should the plants need the moisture or more holding soil below, they are at hand should a long season of drought ensue. It is, however, not the summer moisture that does the harm, if harm there be; it is rather the winter wet, which if stagnant is calculated in some instances to promote an enfeebled growth in the year

* Drawn for THE GARDEN by H. G. Moon. Lithographed and printed by J. L. Goffart.

ensuing. All this of course can be avoided by lifting, though some authorities incline to the belief that the lifting is attended by weakening consequences. This is, however, not the case when the plants are in the keeping of those who know their likes and dislikes, and, indeed, it may prove of considerable help when properly treated if only by prolonging the season of bloom in the open ground. If we remember that it is well-nigh impossible to have too much of these things during the summer and early autumn months, whether for cutting or the general embellishment of the garden, it will not be regretted if a portion of the stock is each year reserved for the purpose. The success which has invariably attended the planting of dry stock of these things during the early spring months frequently as late as April is the best proof that the harm result-

those gardens where, so far as the soil and other local conditions are concerned, there is no real need to lift the roots the above plan should be of value for the lengthened display of flowers it provides. With such quick-growing and plentiful kinds as Pottsi and *Crocsmiiflora*—so generally referred to *Montbretia*, but now included under the above name—the above plan may more freely be adopted than with perhaps the more recent hybrids, which are as yet not so abundant.

Another beautiful and popular member of this race is the well-known *Tritonia aurea*, more generally referred to by its synonym of *Crocsmia aurea*. There is a giant form of this known as *C. a. imperialis* with handsome orange-scarlet flowers fully 4 inches across. It is somewhat taller in growth, though most attractive on account of the large size and brilliant colour of the flowers. *C. a. maculata* has deep orange-red flowers blotched with brown on the lower petals.

In planting all such things a depth of 4 inches or 5 inches will be found ample, the soil being previously deeply dug and well manured. Manure may be used somewhat freely if well decayed, but at the same time immediate contact with the roots should be avoided. Where annual lifting is indulged in, a less depth for planting will suffice, and if given a mulching later on the plants will not suffer through long drought. With permanent beds or groups the above depth of 5 inches will be enough without the usual orthodox winter mulch, the latter often causing an earlier growth, which is liable to be injured by the keen and biting winds of spring. In instances of deterioration a good time for replanting is during February or early March, before much top growth is made, when a little sorting of the larger roots may be indulged in to advantage, giving the weakened plants a fresh position. Where these beautiful subjects are grown in pots, annual potting or shifting to pots of larger size will be found neces-

Tritonia aurea.

ing from drying such things is of very small moment. Where both systems can be pursued in any one garden it may safely be predicted that a long succession of bloom will be the result. This in itself is an important item, not only for increasing and prolonging the season of flowering, but if pursued systematically should be the means of retaining the stock in its fullest vigour. The spring-planted stock of this year may remain through the coming winter in the soil to give an earlier bloom in the following year, while the batch that had flowered and remained in the ground the winter previous would be the one to be lifted this coming autumn. In this way little loss would be sustained in a single year by deterioration, and the corms if harvested at the right time and well kept, *i.e.*, cool and dry, will more than repay the labour and trouble this lifting in alternate years involves. Even in

sary, employing good rich soil. In pots, however, *Tritonias* require a plentiful supply of moisture, and may be plunged in ashes or other material to modify this as much as possible. Liquid manure may also be freely given till the spikes are well advanced. In pots, as in any position in the garden, these plants attract by their infinite grace of habit as much as colour in the flowers, while in the garden there are no untidy elements to be seen—no dead or decaying flowers on the plants when flowering is over. As the blossoms pass from the early flush of beauty they fall to the ground, leaving the flowering spike and seed-pods as free and as clean as in youth.

By reason of the somewhat numerous and recent list of hybrids mostly belonging to *T. (Montbretia) crocsmiiflora* (said to be a cross between *Tritonia aurea* and *Montbretia Pottsi*), one of the most valuable garden plants

grown, the numbers of beautiful things in this group are greatly increased, a few of the most worthy being *Etoile de Feu*, rich orange and yellow; *Gerbe d'Or*, golden; *Soleil Couchant*, a very free variety, golden yellow; *Transcendant*, orange-vernilion shade, one of the most showy; *Aurore*, orange-yellow, very large and effective; and *Phare*, reddish-crimson. These, together with *Crocsmiiflora*, *Pottsi* and its variety *grandiflora*, make up a very beautiful set of equal hardness and usefulness in the open garden.

The lovely species in the accompanying plate, *T. crocata*, is a charming plant from the Cape of Good Hope, better suited in this country to frame culture; or by starting it early into growth each year it may be transferred to the open when well established, selecting a warm and sunny position where perfect drainage is secured. Of the beauty of this little-grown species, and particularly its exceptional colour, the coloured plate in the present issue amply testifies. E. J.

THE WEEK'S WORK.

KITCHEN GARDEN.

MULCHING AND WATERING CROPS.—After a long period of sunless weather we now have in the southern parts of the country drying winds and heat, so that the vegetable crops are quickly affected. To get a fair return it will be necessary to water freely and mulch also. I pay more attention to mulching, as water, no matter how well applied, is so soon lost on a hard surface, that when crops can be mulched, a thorough watering once a week will suffice, indeed, be better than several waterings. It is not always an easy matter to mulch growing crops, the material not always being at hand. Unless such crops as Peas and other surface-rooting crops are mulched in light soil the crop soon fails and there are serious losses. I am obliged to use various kinds of materials. One of the best is spent Mushroom manure; this conserves the moisture and keeps the roots cool. Of course litter of any kind will suffice, but in light soils cow manure is a splendid mulch, and after its purpose is effected it may be dug into the land for future crops. In heavy soils I have found leaves partially decayed an excellent mulch for quick-growing crops, and these retain the moisture. Salads and other quick-growing crops soon suffer from drought, and the flavour is affected if growth is arrested. I would advise filling in between the rows with short litter, and to such crops as French or runner Beans a liberal coating of short litter each side of the rows will be beneficial, and if possible copious supplies of liquid manure given once a week will keep the plants in full vigour. With crops that make a strong top growth it is well to sow in rather deep drills or trenches, as water or food may be given more freely. In the case of Peas in full bearing a few days' heat and drought soon make the pods shrivel, but if the roots can be kept going there will be a full return. In gardens where water is none too plentiful I have found it a good plan to damp growing crops overhead at sunset. French Beans, salads, and Vegetable Marrows are much benefited, as the moisture on the foliage wards off attacks of red spider. I am not in favour of giving water in small quantities at any time if it can be avoided, but I would advise watering overhead to keep the foliage clean. Newly planted autumn and winter crops such as Brassicas will need moisture, and a thorough watering that will reach the roots should be given weekly. In most soils it will be found that the crops will be greatly benefited if the hoe can be kept going, this preventing the earth drying and cracking.

SPRING CABBAGE. I advised a later sowing some three weeks ago. Though the earlier sown plants will be none too large in certain soils and

localities, I am aware many growers think the end of July quite soon enough for this crop, and I would add it is not well to defer sowing the same, as in seasons of heat and drought the seed does not germinate so quickly. I advised Ellam's Dwarf for first spring crop, and I do not think it can be beaten. For a later sowing I have found Flower of Spring and April splendid varieties. These are compact growers, dwarf, and of just the size for a private garden. They closely follow the earlier sown, are of splendid quality, and their dwarf habit makes them hardy. In sowing at this date I would urge the importance of ample room in the seed-bed, a rich soil to promote rapid growth, and an open quarter to get a strong plant. I place much importance on the autumn growth of the plants as to wintering well. Seed sown earlier in the month should not suffer from want of moisture, which should be given freely in the evening, and in the case of newly sown beds the surface soil may be covered to assist germination.

EARLY POTATOES.—These from the early part of June are lifted as needed, but at this date I do not think there is any gain in leaving ripe tubers in the soil, as the hot sun in thin, sandy soil dries up the sap too rapidly and causes loss of flavour. For seed I have found most of the first earlies ready to lift. Of course, the skins may be hardened by exposure, but I do not advise too much exposure to the sun. I prefer a north border to a south one, turning the tubers over frequently. Of course, these remarks apply to a sheltered garden and in a warm locality. In the north and on heavy clay soil growth will not be so far advanced. My best early Potato this year has been Ninetyfold. This crops grandly, and is the earliest. As regards the keeping of the Ashleaf and early kinds, when lifted they should be given a cool store; an underground cellar is suitable, as here is an even temperature. There is a great advantage in early lifting, as now there is no sign of disease, and the land can be utilised for green crops, such as late Kales, Broccoli, and Spinach. For the Spinach it will be well to give the surface soil a dressing of lime, or failing this, burnt refuse and soot, to clear the ground of insect life.

LATE CELERY.—The planting of this in this part of the country has been delayed owing to drought and the lateness of the early Potato crop. In many gardens Celery follows the early Potatoes. For the latest Celery I am not in favour of placing a great quantity of rank manure in the trenches, as I find the best-keeping Celery is that grown with only a small quantity, giving the foot in the way of fertilisers when in active growth. Grown thus there is no need for deep trenches, and there is less labour in preparing the soil. Of course, late plants in a dry hot July or August need liberal supplies of moisture at the start, in fact, they should never be dry at the roots during the growing season. I find soot, salt, and liquid manure splendid fertilisers, and these given weekly from September to the end of October will cause a good growth. I plant direct out of the seed bed into shallow trenches. The plants are grown thinly from the start. If large quantities of Celery are needed for flavouring or soups, it will be found advisable to plant for this purpose. I plant in deep drills in rows 2 feet apart, 12 inches between the plants, and mould up with a hoe. This makes splendid flavouring material, and keeps sound well into the next spring. For planting now I have found Standard-bearer the best. This is a medium grower and an excellent keeper.

WINTER GREEN CROPS.—Since my last note on the cropping of the land there has been unavoidable delay, and I fear in many gardens where double cropping is a necessity few have got in their winter crops as early as desired. The advantage of thin sowing and transplanting or pricking off into beds was never so patent as this season, and I fail to see why green crops needed for July planting are often sown early in March. It is impossible to get a good fibrous-rooted plant after being so long in the seed-bed. I could not plant the bulk of the Kales and Broccoli till I had cleared a large quarter of early Strawberry

plants, and this year I am quite three weeks later. Much depends upon the plants. If at all weak or drawn from crowded seed-beds, they will have a difficulty in making up lost time. In planting at this date I would advise drills for the plants, as moisture will be needed, and unless it goes down to the roots it does little good. I have not been able to wait for rain before planting, and have been obliged to puddle in the plants, as the season is so far advanced. I find it advisable to plant the earliest varieties of Broccoli on a piece of land that can be cleared before the winter, as a large portion of the crop is cut in November—I mean Protecting Broccoli, reserving special quarters for late kinds, not planting all in one place, as it is well to make two or more plantings of Model, Late Queen and such kinds. Savoys may with advantage be planted on an east or north border, as these are more valuable when late. If planted early they split badly in severe weather. The same remarks apply to Kales, such as the Cottager's or Dwarf Curled Scotch. A much later supply will be secured from plants on a cool border, and this is a strong point, as in April green vegetables are getting scarce. All kinds of early planted green crops should be gone over, making good all blanks in case the club has attacked the plants. Far better destroy and make another plantation of another variety, and in clean soil, giving the affected quarter a thorough cleansing and good cultivation previous to planting, or, if possible, a rest, turning up roughly to sweeten and pulverise the soil.

PARSLEY.—Having a great demand for Parsley, I always sow a liberal quantity at this season, taking advantage of the first rainfall to get in the seed. To get the best results thin sowing is a necessity, also rapid germination. By sowing now the crops winter better than when sown several months earlier. I admit the leafage is not so fine, but a medium growth is much harder than a larger one. If sown thinly, the roots will give a fair return next November. It is well to use soot freely previous to sowing; indeed, in a light soil, I am sorely troubled with wireworm, one of the worst pests the plant is subject to. For this I use gas-lime and soot, and am free for a couple of years. Plenty of manure and good cultivation promote rapid growth. If the seedlings are too thick it is well to thin early, then give a good watering to settle the soil round the plants. Older plants that have produced seed-stalks should be cut over and given liquid manure, soot-water, or a dressing of soot in rainy weather. In many cases old plants are not worth keeping another year, as much better crops will be secured from seed sown now. S. M.

HARDY FRUIT GARDEN.

SUMMER PRUNING, NAILING AND TYING, &c.—In many instances summer pruning is frequently done too soon in the season, with a view, no doubt, oftentimes to promote an orderly appearance, but at the same time not so conducive to the development and formation of fruit-buds as of secondary growth. My own ideas of this particular work were confirmed only last year in a conversation with a well-known and expert fruit grower in the trade whose experience of the evil of secondary growths was the same as my own. This work will be attended to in my case now and during next week, and as it does not take long when set at with a determination to push it through, it will soon be finished. In summer pruning due regard must be had for future extension and allowance made as to length of shoots to be left, &c. Another important point also is that of non-fertility in any particular fruit or variety, as in some cases by extension better crops can be had. I have noted this in the case of horizontally-trained Pears, in which by depressing the shoots instead of cutting them off better results were obtainable. The regular methods of procedure when they do not give results should be departed from without any hesitation. Do not

when adopting the usual course of summer pruning cut back too close, but rather leave a bud or two in the event of a slight woody growth again pushing. A good rule is to note the condition of the shoots on such as Pear trees, and when it is seen that the growth has ceased extending, then set about pruning. When afterwards attending to nailing or tying, guard against the laying in of too great a number of shoots. At the same time do the work well, paying especial attention to all trees still in the process of formation by equalising the shoots as far as possible so as to secure well balanced examples. Avoid the retention of as many foreright shoots as possible: these oftentimes look unsightly. If cut away carefully now the wounds will be more likely to heal over in a satisfactory manner. Such as Peaches and Nectarines in my case are already tied in, nailing being dispensed with, preference being given to wiring instead. A few more leading shoots may have to be secured, but all lateral growths will be nipped out in quite early stages. The growths on these are now perfectly clean and healthy, whilst the crop, all things considered, is not at all a bad one. Guard against tying too tightly to wires, more especially to galvanised wires, from which more injury need be apprehended. With the shoots all in their places the work of syringing will be an easier matter. Do not cease this until each respective variety commences to show colour, which in the case of the earliest may already have begun in favoured localities. When dealing with pyramid, horizontal-trained or other forms of espalier, and with any other dwarf method of culture, do not be unduly severe in pruning at this season, looking rather for some further extension if it be possible, otherwise in the case of non-fertile trees root-pruning will have to be resorted to later on. I shall now soon go over a young orchard of Apples on the Paradise stock and pinch the points out of the shoots where growth is still active and the trees bearing good crops of fruit at the same time. These trees are being watered freely, owing to the dry weather. Before the last application a liberal dressing of fish manure was applied and at once watered in. Since that, the dry and hot weather still continuing, a mulching of farmyard manure has also been added. The next watering will send an additional manurial stimulant down to the roots. Avoid, if possible, the watering of Cherries with ripe fruits on the trees if there be any indications towards cracking. Morellos will not often show this tendency, at any rate not yet for some time; hence they may be safely watered when in need of it, and that greatly to the benefit of the crop as regards size. Cherries on walls from which the crop has been picked should be nailed or tied, taking out at the same time any superfluous shoots, but bear in mind that this is not done too excessively. Rather lay in all the wood possible if there be any indications of canker apparent. Where the trees have borne a good crop of fruit and the growth is none too luxuriant it will be an assistance to the trees for another season to immediately apply a dressing of artificial manure or of bone-meal. The foundation will then be laid for next year's crop, and a safeguard be in store against the all too frequent failure to get through the stoning process safely. Do not, on the other hand, either manure or water trees that are growing vigorously, but use every endeavour to starve them into subjection. The thinning of such fruits as Apples in order to obtain fully-developed examples, although not frequently done, is a matter well worthy of notice. The present is a good time for doing it, so as to relieve the trees of the smaller and badly-formed fruits. Early Apples, too, in this way may be taken for kitchen use, such, for instance, as Lord Suffield, Lord Grosvenor, and Eeklinville. This is done by the expert market growers, and it will pay in the private garden too. In the case of Plums bearing heavy crops (not this year possibly) the same process of thinning is recommended. Plums even when green and hard make a good preserve, but if gathered with the first tinge of colour upon them they are excellent. The trees

that are bearing heavy crops will thus be greatly relieved in good time.

BUSH FRUITS. A partial pruning of Gooseberries now will help to arrest a late growth, which may otherwise be possible. The cordon or any other fence form of training the Gooseberry makes it a necessity to do a moderate amount of pruning. Currants in the open will soon be all cleared of their fruit unless it be a few late bushes, as of Late Rivers, which keeps well if secured against birds. Where the growths are seen to be unduly thick it will pay to thin them out now or to adopt a general process of stopping as soon as possible. See that both Gooseberries and Currants against walls are well protected from the depredations of birds, and at the same time give an eye to any appearance of caterpillars, which afterwards will very likely escape notice.

NEW PLANTATIONS OF STRAWBERRIES.—Give attention as speedily as possible to the preparation of sufficient ground for making new plantations. If it be the custom to still retain the beds for two years, part of the work at any rate has to be done every year, or at least it should be. As far as practicable let the position chosen be free from the shade of trees. If for first early varieties, choose the warmest spots; if for late kinds, preference should be given to cooler borders, whilst the main crop may be on open garden ground. If the ground were trenched for the previous crop, say for Peas, Cauliflowers, or the like, that rather tedious operation can now be dispensed with and bastard trenching be done instead, *i.e.*, digging the top spit and forking up the trench, which will give a depth of at least 18 inches. All new Strawberry beds should be made if possible by the middle of August. See that a good proportion of manure is added. If farmyard manure be scarce, then a good substitute will be found in fish manure, which if immediately dug in cannot be complained of as a nuisance. The young plants will soon find a benefit from this manure.

OLDER BEDS.—If kept for another year these should be cleaned off as soon as possible after all the fruit is gathered, all useless runners and possible weeds too, and if need be watered as well. These beds to be destroyed should be disposed of without delay, and the ground be brought into use as speedily as possible for a vegetable crop. **HORTUS.**

Iris Kämpferi.—Whether known by the above name or that of *I. levigata*, this Japanese Iris again asserts itself as one of the most beautiful plants that we have in flower at the present time. Some of the varieties have the flowers striped and splashed in quite a startling manner, but to my mind the self-coloured flowers are far more pleasing than these. Considerable numbers are sent here from Japan every winter when dormant, and among them is generally a fair sprinkling of a form with large double flowers of a rich Tyrian purple, and a counterpart thereof in size and shape, but in colour pure white. These two are, I think, the finest of all, but a great variety of different shades occurs even among these self-coloured flowers. In a Japanese catalogue before me, fifty varieties of this Iris are named and described. They are, of course, increased by division to keep them true, but at the same time if seed is saved from a mixed collection, the progeny thereof will yield blossoms exhibiting a great variety of colour and markings. This Iris is essentially a moisture-loving plant, and is seen at its best on the margins of lakes or streams, but where there is no such spot available, it may be grown in a satisfactory manner in the open border if the plants are well watered when necessary. To facilitate this they should be planted in a little hollow, when watering is an easy matter. Even then the flowers never attain the dimensions of those grown by the water-side, but as a rule they expand sooner than those that are in wetter spots. During a hot and dry season the border plants are very liable to be attacked by unusually large black thrips, which soon dis-

figure the leaves. Those imported from Japan are generally sent here in the masses of clay in which they have grown, and, being packed in boxes, the interstices are filled with soil. In this way they mostly reach here in fine condition, and planted out many of them will flower the first season. Some fine flowers of several varieties were shown at the last meeting of the Royal Horticultural Society.—T.

ORCHIDS.

LELIA ELEGANS.

THE origin of this plant is without a doubt clear enough, being a bi-generic hybrid between *Lelia* and *Cattleya*. *Lelia elegans* has been so long known as such, that the longer appellation *Laelio-Cattleya* comes rather slowly into use. It is a grand plant and worthy of the widest culture, for it is extremely variable, yet good in all its forms, showy, and flowers over an exceptionally long period. During the present season I noticed it flowering in April, and the later forms are seldom over before September, so that six months of the year at least are brightened by its lovely blossoms. The habit of the plant is rather variable, the stems usually tall and erect, the flower-spikes appearing between the apical leaves, and bearing few or many flowers according to the variety or the strength of the individual plant. Again, in the growing and resting seasons the plants differ, some specimens keeping quite dormant after the flowers are past, while others make a secondary growth. The natural habit in all seems to be to grow quickly, flower, and when the pseudo-bulbs are fully developed take a thorough rest until spring. Plants that keep to this routine are also more long-lived under cultivation and generally healthy, but with all our care it is not always possible to keep them dormant until spring. The cooler and drier in reason they are kept after the growth has quite developed the better, but this must not be so severe as to cause the least shrivelling of the bulbs or leaves. One may have a *Dendrobium*, an *Aerides* or many other Old World epiphytes shrivel badly, and after a few weeks of good treatment swell up and be as vigorous as ever, but the *Cattleyas* and *Laelias* will not so quickly recover from this sort of treatment. When the roots are actively searching for moisture and growth is free the plants like an almost unlimited supply of water both at the roots and in the atmosphere, but when at rest they should be treated accordingly.

Being a vigorous-rooting kind when in health, *L. elegans* may be allowed fairly large pots or baskets. Either are suitable, and by placing a weak or unhealthy plant in the latter and keeping it well up to the light I have often obtained larger and better growths. Like its relative, *L. purpurata*, it likes a very rough open compost that the roots may freely enter, and where air and water filter freely through. Drain the pots thoroughly and cover the crocks with about half an inch of rough Sphagnum Moss. When potting becomes necessary—which is seldom—keep the leads as near the centre of the pot as possible, as by this means the growths for three years or more will have the advantage of entering the compost rather than rambling over the edges of the pot. The roots take freely enough to the pottery ware and are as long-lived as may be expected, but unless there are continuous dampings and syringings the growths lose strength, owing to the limited supply of moisture obtained. Keep the bases of the plants well up by rounding the compost, and as far as possible see that

every lead rests on the surface. If too high the plants are half-starved, especially if insects of the character of woodlice and small snails are allowed to get at the young roots before they enter the compost, while low potting is as great an error owing to the liability of the young shoots to damp. If possible, choose the time when the young growths emit roots freely for potting, and this as often as not is directly after flowering. Plants out of health and in bad condition at the roots are better shifted and given new material at any time of year than allowed to go on and die back inch by inch owing to sour compost. Such plants after shifting need very careful atmospheric treatment, a slightly higher temperature and more shade, the roots being assisted by judicious moistening to run out and establish themselves in the new compost. Ordinarily the usual *Cattleya* house temperature and atmosphere suit it admirably, the plants growing on from year to year and making fine specimens. The great variety of the forms makes it useless to describe any one, but that usually looked on as the type has rosy sepals and petals suffused with white, and a tinge of yellow at the base; the lip is three-lobed, the blotch in front being a deep and beautiful crimson-purple. Among the finest varieties are *L. e. alba*, *prasiata*, *Schilleriana*, *Turneri* of which a coloured plate was published in THE GARDEN of May 23, 1896—and *Wolstenholmie*. It was discovered by a Belgian collector, Devos, while on a journey for the late M. Verschaffelt, of Ghent. This was about 1847, and the plant at that time is said to have attracted a great deal of attention. Many importations, of course, have been made since then, and it is well represented in collections, but even now the plant is by no means overdone, and it always sells well and freely. **H. R.**

Cypripedium Pearcei.—The peculiar Reed-like foliage and pretty flowers of this species make a distinct and attractive plant. It is not so much grown as it deserves, possibly on account of its reputed shy-flowering habit. But in some places it grows and blossoms with the greatest freedom alongside other warm-house Orchids. One thing necessary is to get the plants well established and growing healthily. Flowers are then usually produced with freedom. Coming from Peru, too great heat is inadvisable.

Oncidium Papilio.—In a warm, moist, and extra sunny house this pretty *Oncidium* is never out of flower. I have an exceptionally free and good form of it, but only one plant of this especial variety lived out of a large clump imported some years ago. This, at present, has three flower-spikes, and is growing in a four-inch pot, the marginal band of deep reddish brown spots on the lip being exceptionally rich. The plants are very averse to much compost, but like plenty of water at the roots while growing.—H.

Dendrochilum filiforme.—Though small individually, the slender graceful racemes of flower produced by this species are extremely pretty. The flowers appearing with the young growth, the roots must at this time be thoroughly moist. The plants, too, may be repotted as soon as possible after the flowers are over, as this allows of the young roots entering the new compost. The plants like a shallow rooting space and plenty of drainage, good peat and Moss sufficing for compost. The best position now is in the warmest house. *D. filiforme* is a native of the Philippine Islands, and was introduced in 1840.

Cattleya Hardyana.—This lovely *Cattleya* is now in bloom, and should be grown by all who care for beautiful Orchids. A natural hybrid between *C. gigas* and *C. Dowiana aurea*, it combines the large size of the former with the

exquisite lip-markings of the latter. A plant I have with the flowers now open has been grown in the lightest end of a house principally devoted to Melons, and not with the Cattleyas proper. In such positions it is apt to run away at the base after flowering, but while growing there is no doubt it likes a little extra warmth—at all events the first season or two after it has been imported.—H.

EPIDENDRUM BRASSAVOLÆ.

ANY Orchid of a showy character that flowers after midsummer is useful where a continued display is looked for, and this is not only showy, but very easily grown and free flowering. Indeed, there are many of the Epidendrums with the habit of a Cattleya, or somewhat similar, that if only known by amateur cultivators would go far to enliven and give variety to the houses at this time of year and later. But, unfortunately, if we except one or two of the more popular cool house kinds, Epidendrums seem to have lost the position they once held. Yet there are many lovely plants among them, and perhaps a wider variety than in any other genus of Orchids. The present species is now in flower, the blossoms occurring upon tall, stout scapes where the plants are strong and well established. A specimen in flower this week has five such spikes, with an aggregate of seventy blooms, and just now, when the Orchid season is declining, there are many worse things. As the specific name implies, the flowers bear some resemblance to those of a Brassavola, especially in the trowel-shaped, pointed lip. The sepals and petals, too, are narrow, as in the last-named, in colour a deep cream or yellow, with a purple keel, the lip white, lined with purple. This may not sound a very showy or effective combination, but as a matter of fact it is very distinct and pretty when plenty of bloom is produced.

E. Brassavola is one of the discoveries of the ill-fated Polish collector, M. Warszewicz, who found it high up on Mount Chiriqui. A medium temperature therefore, or where Cattleyas are grown, will suit it well: as a matter of fact, the specimen mentioned has been growing in a mixed house of plants and not too regularly treated in any respect. The roots are fairly vigorous and delight in ample moisture all the year round, especially during the time growth is active. The moisture in the atmosphere must be well maintained and the plants somewhat freely damped overhead at all times when the forming leaves are free and not liable to hold the water. If given a roomy pot the plants will not require shifting often, once in three or four years being ample; indeed, if well done in the first place and a little of the old material removed and replaced by new annually, they go on until the pseudo-bulbs begin to grow over the side of the pot, when a shift should be allowed. If longer delayed the growths will be weak and the flowers, of course, fewer upon the spike. The compost may be similar to that used for their Old World prototypes, the evergreen Dendrobes, the routine of culture being somewhat similar. These Epidendrums are hardier and more easily grown than the latter, and, moreover, flower at a different time of year. E. Brassavola did not flower in this country for some years after its discovery, the first plants to bloom having been sent by Mr. G. Ure-Skinner to Mr. Bateman.

Epidendrum cochleatum.—The flowers of this species are, perhaps, more curious than beautiful and will appeal to lovers of this class. They appear on a rather crowded raceme, about half a dozen together, the sepals and petals being greenish white, the inverted shell-like lip marked with deep maroon-purple. The plant has the habit of a Cattleya, is very free-flowering and easily grown. Repotting may take place in spring, using a rough, open compost and fairly large pots. Water freely when in active growth and allow a good rest if possible, not by drying off the roots, but by a slight reduction in tem-

perature. It does well in the Cattleya house and is one of the oldest-known Orchids.

Cypripedium Sedeni.—This hybrid makes a capital plant for amateurs, being always amenable to the simplest form of culture, and bearing its beautiful flowers for upwards of six months in the year. These, occurring on tall scapes from the centre of the fine leafy tufts, have a more graceful appearance than those of most Cypripediums. C. Sedeni does well in any moderately warm and shady house, either plant stove, fernery or Orchid house proper, and likes a substantial compost. Pot in the ordinary way, no elevation of the plant being needed, and water freely at all times.

Odontoglossum madrense.—The flowers of this species are very pretty and distinct, and it is far from well known. The growth consists of elongated pseudo-bulbs, each bearing a couple of deep green leaves. The spike bears from six to eight flowers, white, and prettily spotted with purple markings at the base of each segment. It is a Mexican plant, and during the summer months does well in a temperature slightly warmer than Odontoglossums like as a rule. Small baskets or pans may be used for it, and the usual peat and Moss mixture over good drainage. It likes plenty of moisture at the roots all the year round.

Oncidium incurvum.—The pretty spikes of this old species are now in full beauty, and it makes a fine plant for arranging with other Orchids, giving lightness and grace to groups of Cypripediums, Cattleyas, and other large-flowered kinds. The spikes appear when the pseudo-bulbs are partly grown, and as they take a very long time to come to perfection the removal of the plants to a cooler, more airy house than the growing quarters conserves the blossoms and helps to ripen up the pseudo-bulbs. An intermediate temperature suits it well. The plants may be easily grown in the usual mixture of Moss and peat, and never fail to flower freely.

Masdevallia macrura.—The flowers of this species are among the finest in the genus, the long tail, from which it takes its name, giving it the appearance of being even larger than it is. On each occasion I have seen this plant extra strong it has turned out, on inquiry, that more warmth in winter has been given than that allowed the M. Harryana and similar types. Being of strong growth and somewhat of a giant among Masdevallias, rather larger pots than usual may be allowed, the compost being exceptionally rough and open. Though known previously, this fine species was not grown in this country until introduced by Mr. Bull in 1876.—H.

Odontoglossum Pescatorei.—One of the most distinct and beautiful forms of this lovely Odontoglossum was offered for sale on Friday, July 1. The plant, flowering from a small bulb of a recently-imported plant, carried a raceme of six blooms, fine in substance and in shape. The sepals are white, slightly suffused with rose-purple in the centre, with a few bright violet-purple spots in the centre of each; the beautifully fringed petals pure white, with several prominent purple spots in the centre; the lip white, shading to yellow, spotted and lined with brown on the crest. In the centre, in front of the yellow disc, are numerous purple blotches and lines, which extend nearly to the apex. There are also several purple spots on the upper outer

edges of the lip. The price obtained for this fine variety was seventy-five guineas.

ARRANGEMENT OF FLOWERS.

In floral decoration it often happens that the most pleasing effect is obtained by simple arrangements of one flower, as exemplified in the accompanying illustration. Both classes of Hellebores, the Christmas and the Lenten Roses, come at a time when the garden produces little for indoor decoration. True, there are the lovely Iris stylosa and its white variety, and there are generally some spikes of the Winter Flag (*Schizostylis coccinea*) in bloom during the time that the giant Christmas Rose (*H. altifolius*) is at its best, while the Winter Sweet (*Chimonanthus fragrans*) is also an open-air contemporary. The Lenten Roses often commence to bloom in January, and with these during their flowering period are associated the

Christmas Roses. From a photograph by Mr. J. Gregory, Croydon.

early spring bulbs, but none of these subjects, beautiful as many of them are, should be used for floral arrangements in conjunction with Hellebores, the latter invariably creating the most artistic picture when arranged by themselves in a vase or bowl. It is advisable before placing them in water to slit the flower-stems into four divisions with a sharp knife, making the cuts from the base upward to a length of about 4 inches. This prevents the flowers from becoming flagged, which they quickly do if this expedient is not practised. The Lenten Roses, of which a beautiful coloured plate appeared on June 4, have such abundant foliage, that no difficulty is experienced in adding a few leaves to their flower-sprays, which are themselves furnished with leadlets, without damaging the plants, but in the case of the Christmas Roses if leaves were plucked every time a bowlful of flowers were gathered, the plants would soon become denuded of foliage and thereby weakened. The blooms of *Helleborus niger* and its varieties are far more solid in appearance, and are carried with greater rigidity on the footstalks than is the case with *H. orientalis*, and therefore leafage possessing something of the firm and close texture of their natural foliage proves the most effective

substitute, and leaf-sprays of the common *Rhododendron ponticum* have been proved to lend themselves to this association with good effect when feelingly arranged. Naturally, where the leafage of the Christmas Rose is sufficiently abundant to provide the needed greenery without injuring the plants no substitute is necessary, but this is rarely the case with such a profuse blossomer. I may have made it appear in the earlier portion of this note that I am averse to floral arrangements composed of more than one flower; this, however, is far from being the case, the beauty of many colour-contrasts being undeniable. I have before me now a charming composition of blue Cornflowers and white Galega; a week ago white Madonna Lilies and the lavender flower-sprays of *Erigeron speciosus* proved equally attractive, while many others occur to the mind as having been every whit as happy, such as *Eryngium Oliverianum* and *Alstroemeria aurea*, the Madonna Lily and the buff Day Lily (*Hemerocallis fulva*), the blue *Salvia patens* and yellow Paris Daisy, but in specifying these few pleasing colour effects one is conscious of a host equally deserving of commendation that perforce remain unmentioned.

S. W. F.

ROSE GARDEN.

ROSES AT COMPTON HOUSE.

THE strongest feature in this place is the Roses. I never remember to have seen so many or grown in so many forms in a private place before. Evidently the soil is favourable to their growth, as I could hardly see a poor plant. Standards were in strong force, and although I am not a great lover of Roses grown in this way, yet I must confess I admired a vigorous bush of Cheshunt Hybrid, 5 feet across and almost touching the ground. *Homère* was nearly as large and literally covered with its lovely pinkish blooms. *Mme. Plantier* grown in this way was quite a sight. In this state standard Roses are lovely. *La France* was beautiful—so different from what I have in these gardens. *Margaret Dickson*, *Boule de Neige*, in fact all the best Roses were to be found here. Beautiful as *H. Perpetuals* and *Teas* are, I could but admire the bunch Roses. *Crimson Rambler* and *Bennett's Perpetual* were growing over a big old Yew tree that was dead, but had been set up in a conspicuous place to train these free-growing kinds over, and right well they looked.

On an iron fence I found many kinds of climbing Roses, with a few others, such as *Chinas*, &c., in many colours, all allowed to grow at will and hiding the fence.

Although Roses are grown so largely in the open air, they are given a place under glass, a house being devoted to them. Several of the strongest growing *Teas* and *Noisettes* trained up a trellis are brought into flower very early in the year. In a slip of the kitchen garden I noticed a fine collection of all the best *Teas* in pots of various sizes, from 6 inches upwards, and, judging from the way Roses are grown here, they may be had in bloom all the year round. In an outside portion of the pleasure grounds I found a garden of Roses; these were all dwarfs and mostly of the H.P. class, such as *Marie Baumann*, *General Jacqueminot*, *Souvé de la Malmaison*, and many others were splendid.

J. CROOK.

Forde Abbey.

Rose Joseph Bernacchi.—A plant growing in bush form and pruned long has been lovely this year. The fine trusses are thrown well up

above the foliage and the pale sulphur-yellow blooms are very distinct among climbing kinds. The flowers are moderately full and the petals of great depth. Although it is classed as a *Noisette*, I consider it as much a *Tea* Rose as *Belle Lyonnaise*. It would make a grand standard, for its growth is good, but not so rambling as in the Dijon tribe. It was sent out by *Mme. Ducher* in 1879. Many a Rose has come and gone that was not half so good as this one, and it should certainly find a place in every collection.

Rose A. Maile (Bourbon).—It is surprising this Rose has not become more generally known. In the first place the form is very regular, and there is the exquisite circular arrangement of petals as seen in *Charles Lefebvre*; indeed, one would take it to be a carmine coloured form of the latter and quite as fragrant. It is a true Bourbon. The growth, which is very strong, is after the style of *Mme. Isaac Pereire*, but the foliage has rather more of the reddish hue so peculiar to many of the Bourbons. It is best grown either as a standard or trained in pillar form, or if desired as a bush it must be sparsely pruned, for it is rather a shy bloomer until it becomes well established.

Rose Golden Fairy (Polyantha).—This variety of the late Mr. Bennett's raising will not compare with such as *Gloire des Polyantha* for garden decoration, but the flowers are as perfectly formed and as double as those of an *Anna Ollivier*, but so tiny that the individual blossoms are less than an inch in depth. In form it is, perhaps, the most exquisite Polyantha variety in cultivation. It is rather a far-fetched description to call it golden, for the fully developed blooms are white with just a suspicion of cream at the base of the petals. The buds and some of the blooms, however, are pale apricot shaded, a fact which no doubt is responsible for it receiving the above name. The growth is strong, rather more so than in the majority of the tribe, and its habit is very bushy.

Rose Mme. Jules Grolez (H.T.).—I shall be much mistaken if this Rose does not prove to be one of the best of M. Guillot's introductions. At first sight one would take it to be *Mrs. J. W. Grant*, but there is a marked difference in form. The petals of *Mme. J. Grolez* are less massive and shell-like, but we have the charming petals, especially the outer ones, of the true *Cactus Dahlias*. The colour, too, in the open flower is of the rich imperial pink seen in the buds of *Mrs. W. J. Grant*. In saying this much for the Rose under notice I do not desire to disparage in any way the grand Hybrid Tea which Messrs. Diekxson have given us. In my opinion both varieties will be in much demand for many years to come. *Mme. J. Grolez* is superior in fragrance to *Mrs. Grant* and the growth is of a reddish colour.—P.

Rosa gigantea.—I fear that my inquiry (p. 447, vol. liii.) as to the behaviour of the above Rose in England will prove as fruitless as did "J. R. D.'s" on the same subject six years ago, for the only note that has appeared on its culture in this country since mine was written, some six weeks ago, is signed by "J. R. D." himself, and states that one of his Roses is still alive on a wall at Reigate, but has not up to the present time produced a flower. If no evidence can be obtained of this Rose flowering in England it is undoubtedly at home on the shores of the Mediterranean, as I am informed, through the courtesy of Lord Brougham, that in his garden at Cannes it made shoots 40 feet or more in length during the last season and flowered in April, the individual blooms having a diameter of 6 inches. It seems a pity that *R. gigantea* should not be given a trial on a wall in some sheltered spot in South Devon or Cornwall, where *R. levigata* grows so rampantly. Doubtless if *R. gigantea* was suited by the conditions of soil and climate it would make vigorous growth and soon cover a large expanse of wall, if we may judge from its behaviour at Cannes. I was informed the other day on hearsay evidence that in its native habitat this Rose

attained a height of 200 feet. I lately measured some blooms of the *R. levigata* growing at Kingswear, and found that several exceeded 5 inches in diameter. Surely this is a considerably larger size than *R. sinica* or the *Camellia Rose* attains on the Mediterranean shore?—S. W. F.

NOTES AND QUESTIONS.—ROSES.

Monthly Roses.—Will any of your readers tell me how it is my Monthlies are dying off? I bought them in France, and I find they have all been grafted on the seedling Brier. Just when I expected them to be getting strong they are shrivelling up and many are dead.—S.

Rose Alister Stella Gray—I am rather disappointed with this Rose, not but that it is very effective and free, but the yellow tint of the opening flowers so soon fades away, that the blooms become almost pure white when fully opened. It certainly does not retain its colour nearly so well as *W. A. Richardson*, and will not in my estimation supersede it, which I believe it was supposed it would do when first introduced.—A. W.

Rose Souvenir de Lieutenant Bujon (Bourbon).—This reminds me much of a fine variety named *Boieldieu*. The flower is very large. In colour it is a rosy pink, and is a trifle dull. The growth is very vigorous; in fact it would make a very good climber or pillar variety, and its fragrance is delightful.—P.

Rose Mrs. John Laing.—This grand Hybrid Perpetual was seen in magnificent form at the recent meeting of the National Amateur Gardeners' Association in the Royal Botanic Gardens, Regent's Park. The blossoms were of large size and grand in colour. They were grown by Mr. G. W. Cook at North Finchley, and a silver medal was given them.—B.

Rose Jules Finger.—In colour this Rose very much resembles *Mme. Lambard*, but is a shade or so lighter and not quite so free blooming. It is a good compact grower, and does well on the seedling Brier. It is very fine for cutting in a half-opened condition, and should be grown wherever there is a demand for this beautiful class of Rose.—A. W.

Rose Jean Ducher.—This Rose has also bloomed magnificently this season, and its beautiful salmon yellowish tints have been developed to perfection. It succeeds extremely well as a bush on the seedling Brier, its habit of growth being compact and upright, without the slightest tendency to become straggling. It should make a good garden Rose in favourable situations. It blooms freely, and a group of it would make a fine show.—A. W.

Rose Mme. Pierre Cochet (Noisette).—Just now the colour of this splendid novelty is very rich. There is a vast difference between this variety in colour, form of bud, and growth and its great rival, *W. A. Richardson*. Save the heavy scarlet markings on the outer petals, the colour is uniform throughout and with none of the white edge to the petals as seen in *W. A. Richardson*. As a bud, *Mme. P. Cochet* is quite half as long again as *W. A. Richardson*, and the shape for buttonholes is perfect. Another great advantage is that it flowers freely as a bush. The Brier is the best stock for this Rose.

Rose Mme. Lambard.—In "D. T. F.'s" list of Roses for culture under glass I rather expected to find this lovely *Tea*, one of the very best for the purpose, as it is of free growth, flowering in abundance, and of a lovely tint. I know of few varieties that produce such beautiful button-hole flowers as this, and though the tints vary a good deal according to the season, they are always beautiful. I agree with him as to the beauty and free-flowering of these beautiful *Teas* when grown in the way he describes. They are hardly ever without flower in quite a cool house, while if lightly shaded and well fed during hot weather, the flowers are at all times of good substance.—H.

Rose White de Meaux.—Everyone should possess this delightful miniature Provence Rose. The *White de Meaux* is, however, the

most charming of all. Its flowers, very little larger than a penny-piece, are pure white over about three-fourths of the blossom, but the centre is a rich pink. The petals are prettily scalloped and slightly fimbriated, and the expanded blossoms are usually surrounded with about nine tiny buds in various stages, so that when all are developed the result is an effective spray. As it is very dwarf, similar in this respect to the old De Meaux, it would make a pretty edging to beds of summer Roses. There is another Rose of the name of De Meaux, but it belongs to the Moss tribe.

STOVE AND GREENHOUSE.

ASPARAGUS SPRENGERI.

ALTHOUGH this species has made rapid strides in public favour on the Continent and America, it does not yet seem to have attracted much notice in British gardens. Grown in pots or in

Naples, through their collector, Herr Sprenger, after whom the plant was named by the late Dr. von Regel, director of the St. Petersburg Botanic Gardens. In habit it approaches *A. sarmentosus* and *A. falcatus*, but has flatter leaves, or rather phylloclades. The small white flowers are produced in great profusion and emit a pleasant perfume.

NOTES ON PELARGONIUMS.

THE regal and show section is getting past its best, and by the end of July the plants should be stood outside, not quite in the full sun for a few days, but in an open and airy position. This precaution is especially necessary when they have been flowering in half-shaded positions in conservatories or have been used for indoor decoration. If placed quite in the sun the foliage suffers, and this causes a check to the roots, the plants afterwards refusing to start freely. But in a few days they may go to quite

the laterals. The shape of the plants the next season will be much improved if they are well cut back now, no staking or tying being necessary for many of the stouter growers, while even the weak ones will be improved. Give no water after cutting down until the young shoots are seen to be starting, when one thorough soaking will put them right for repotting. The earlier in reason this is done the better. The size of the pots will depend upon how the plants are doing, but, as a rule, the pots will need to be smaller than those they have flowered in, the roots having been shaken quite clear of the old compost and a few of the larger ones cut off. The soil at this potting should not be rich, good loam, leaf-mould, and a little sharp sand suiting them well. Pot very firmly and return to the sunniest spot at command. During the autumn the aim of the grower must be to promote a slow, but very hard and solid growth, and to this end a somewhat free thinning of the shoots should be practised.

Asparagus Sprengeri. From a photograph sent by Mr. C. Halford Thompson.

suspended baskets, it has a very ornamental appearance, the shining, deep green sprays hanging over gracefully. For bouquets and table decorations it promises to become very popular. *A. Sprengeri* is a native of Natal. It was introduced in 1890 by Messrs. Dammann and Co., of San Giovanni à Teduccio, near

an unshaded place and be kept considerably drier at the roots preparatory to cutting down. It is quite a mistake to take only the ends of the shoots. If strong and vigorous growth is looked for, the flowering wood must be cut back to where it is quite hard and well ripened, of that brown tint that Vine growers like to see

bloom, and if judiciously fed with a little chemical manure the flowers will be as good at the latter end of the season as at first. The number of plants will depend, of course, upon the size of the baskets, but they are prettier when not crowded, while as to colour there is no lack of variety.—H.

ZONAL PELARGONIUMS.

— Old plants of these cut back a month ago are now starting well, and these, with the spring-struck cuttings for winter flowering, may be potted up. Until the end of August, or longer should the weather prove hot, they may remain in the open air, but directly cold or wet weather seems imminent the plants must have the protection of a frame. Light frosts occur in September often, and these, though apparently doing little harm, weaken the foliage, causing this to drop later in the season and the plants to produce weak flower-spikes. The scented-leaved section is especially impatient of cold or an unduly damp atmosphere, and as these are principally cultivated for their foliage, even greater care is necessary. There is no need, of course, to close the frame by day or even on warm nights until quite the last thing, so if the plants are arranged thinly they have the full advantage of open-air treatment with no risk of injury from damp or cold. The Ivy-leaved kinds are perhaps the hardiest of all, but even these must have a little protection. Routine treatment will consist in thinning the shoots of the scented-leaved and zonal kinds and keeping the flower-buds closely picked out of all for the next two months. The Ivy-leaved will also, of course, require occasional pinching at first, and subsequently the young stems must be staked and tied. It is now a good time to make up baskets of these pretty plants for winter flowering in the conservatory, and the amount of flower they produce is remarkable. From the end of October until

May or June the plants will

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 26.

THE high standard of excellence which has been manifest in the fortnightly meetings for a long time past was fully maintained upon this occasion. At the previous show the Roses were the predominant feature, whilst on Tuesday last the interest was centred in the Bamboos, of which it may be said, without any fear of contradiction, that no such exhibit has previously been seen at any meeting either in London or elsewhere. The Bamboos gave a charm to the meeting not attainable in any other exhibits. Both Mr. Freeman-Mitford and Messrs. J. Veitch and Sons are to be congratulated upon their efforts to make their exhibits of Bamboos a great success not only from an educational point of view, but also from that of effect. This is what should be the aim of the council, viz., to afford actual illustrations of whatever subject is to be lectured upon at each respective meeting, and thus impart to the Fellows and the horticultural public every information available. We want to see more of this and less of the every-day flowers and plants such as can be bought from the coster's barrow or from second-rate florists' shops. We are glad to see that a decided improvement is manifest in this direction, owing in a great measure no doubt to the wise action of each committee not to recognise to the same extent those exhibits which from the actual display they make may be very good, but which lack both novelty and variety. Exhibitors will do well to note this, and in the future act accordingly.

Of other exhibits prominence should be given to the hardy flowers, among which the Lilies, Roses, Carnations, and herbaceous flowers were most conspicuous. A most instructive exhibit of Ferns was again contributed by Mr. H. B. May, the genus *Pteris* on this occasion affording a beautiful display. A few examples of the new or rare Water Lilies (hardy vars.) were contributed and duly recognised.

Of fruits, the most prominent feature was the admirably-grown and profusely-laden examples of Gooseberries in pots, with a few plants of early Nectarines in addition. Superb fruits of the choicest dessert Cherries were also shown.

The lecture was one of special interest, being upon "Bamboos," by Mr. Freeman-Mitford, who is a recognised authority on these plants. It was listened to with marked attention throughout. The lecturer dwelt fully with the subject from the utilitarian, the commercial, and the ornamental point of view, expressing his firm conviction that there is a great future for Bamboo culture in this country.

Orchid Committee.

A first-class certificate was awarded to—

LILIO-CATTLEYA INGRAMI GIANTEA.—This is not only larger in every respect than the typical form, but it is also remarkably distinct. Very little of the yellow markings and deep purple seen in the typical form is distinguishable in this variety. It was raised by Mr. Seden from *L. pumila* × *Cattleya Dowiana*. The sepals are each 4 inches in length and 1½ inches in breadth, the petals also correspondingly large, deep rose-lilac, veined with a darker shade of colour. The lip is deep crimson-purple, suffused with a darker shade in the centre; the side lobes rose, shading to yellow, with some purple lines at the base. From Messrs. J. Veitch and Sons.

Awards of merit were adjudged to the following:—

MASDEVALLIA IMOGENE.—This is a distinct and pretty hybrid, the result of crossing *M. Sehlimi* and *M. Veitchi*. The ground colour of the flower is rich golden yellow, thickly covered with rich purple small spots, the tails yellow, with a rich brown suffusion, the exterior rich golden yellow.

The flowers are produced on erect spikes, after the manner of *M. Sehlimi*, and the plant exhibited carried three flowers. The growth has the intermediate characteristics of both parents. From Messrs. J. Veitch and Sons.

LILIO-CATTLEYA SCHILLERIANA (Cambridge Lodge variety).—This is a distinct and lovely form of this natural hybrid. The sepals are of a delicate lilac tint, the petals broad, lilac, suffused and lined with purple. The lip is very large and open in front, rich velvety crimson, which is extended into the side lobes and shading to white, with some crimson-purple lines through the throat. A cut spike of two flowers came from the collection of Mr. R. J. Measures, Cambridge Lodge, Flodden Road, Camberwell, where it is flowering for the first time from an imported plant.

Messrs. H. Low and Co., Bush Hill Park, Enfield, sent two finely-flowered plants of *Cattleya Gaskelliana alba*. This is undoubtedly one of the finest of the white *Cattleyas*, the broad beautifully fringed lip, with its delicate primrose throat, forming a remarkable contrast when arranged with the darker section of *Cattleyas*. Two fine forms of *C. Warszewiczii* (*gigas*), a grand form of *C. Mendeli*, a dark form of *Vanda cœrulea* and *Odontoglossum crispum*, with finely-spotted sepals and petals, were also sent (silver Banksian medal). Messrs. J. Veitch and Sons sent a choice collection of hybrids, including *Lilium-Cattleya callistoglossa ignescens* (*C. gigas* *Sanderiana* × *L. purpurata*), in which the sepals and petals are deep rose, of fine form and substance. The large, deep crimson-purple lip, veined with a darker shade of purple, has two distinct bright yellow discs at the base, and is suffused and lined with purple in the throat. In *L.-C. Lucilia* (*L.-C. Schilleriana* × *C. Dowiana*) the sepals and petals are nearly white, slightly tinted with rose, and veined with a darker shade of the same colour. The lip is rich velvety crimson in front, lined with white and yellow in the throat. It is a distinct and pretty hybrid. *L.-C. Amesiana* (*L. crispa* × *C. maxima*), one of the oldest and still one of the most beautiful of this section; *L.-C. Zephyra* (*C. Mendeli* × *L. xanthina*), a pretty form, with the intermediate characteristics of the two parents, the sepals and petals creamy yellow, the front lobe of the lip deep rose, veined and suffused with purple, shading to deep yellow in the throat; *Cattleya Enid* (*C. Mossii* × *C. gigas*), the sepals and petals of fine form, deep rose-lilac, the beautifully fringed open lip deep rose-lilac, veined and suffused with purple, shading to yellow on the disc, which extends well into the throat, where it becomes lined with purple and a bright rose suffusion, were also shown. Messrs. F. Sander & Co. sent *Cypripedium Orion* (*C. selligerum majus* × *C. Rothschildianum*), a distinct form with greenish-yellow ground and purple markings.

Mr. W. Clark, Sefton Park, Liverpool, sent *Cypripedium Mrs. W. Clark* (*C. Ashburtonia expansum* × *C. Stonei*), which closely resembled forms of *C. Morganie*. Mr. N. Cookson sent *Cattleya Lord Rothschild* (*C. Gaskelliana* × *C. aurea*), having the intermediate characters of both parents. Mr. G. W. Law-Schofield sent *Cattleya Hardyana* (Newhall Hey variety), which was not considered distinct from some of the better forms of *C. gigas*. Mr. De B. Crawshay sent a remarkable form of *Cattleya Gaskelliana*, the sepals and petals delicate rose tinted, the lip having nearly a white ground, tinted with rose, with the usual yellow in the throat. Mr. W. G. Groves, Windermere, was awarded a silver Flora medal for a grand plant of *Odontoglossum coronarium*. The plant covered a raft 3 feet 6 inches long and 2 feet 6 inches wide and had sixteen bulbs. It bore two spikes of flower, with thirty-one and thirty-four flowers respectively, each flower being upwards of 3 inches in diameter. It was a wonderful example of culture, doing great credit to Mr. Robertshaw, the gardener, who has grown the plant from imported bulbs in a house with other cool Orchids.

Floral Committee.

The following plants received first-class certificates:—

NYMPHEA GLORIOSA.—A lovely form with handsome flowers of a rich rosy crimson hue. It is a gem among the Water Lilies. From Mr. Leopold de Rothschild, Gunnersbury House, Acton (gardener, Mr. Jas. Hudson).

NYMPHEA OBOVATA ROSACEA.—A sweet-scented kind, with well-formed medium-sized blossoms of a charming flesh-pink hue, the shade of colour almost uniform and extending to the edges of the petals. From Mr. Leopold de Rothschild.

ARUNDINARIA NITIDA.—This is an elegant and beautiful species, and as shown about 6 feet or 7 feet high, a very slender and beautiful kind with lance-shaped leaves, each about 3 inches long, abundantly distributed on the stems and branches. From Messrs. Jas. Veitch and Sons and Mr. A. B. Freeman-Mitford, Batsford Park, Moreton-in-Marsh, Gloucester.

Awards of merit were given to the following plants:—

ROSE SOUVENIR DE MME. LEVET. This is a most welcome addition to the Tea section despite their numbers and beauty. The flowers of this are of a soft uniform chrome orange, exquisite in the bud, and the colour well retained in the open flowers. It is a dwarf kind. From Messrs. Wm. Paul and Son, Waltham Cross.

ROSE CHARLOTTE GILLETOT.—An addition to the Hybrid Teas, the flowers large, nearly pure white, the petals reflexed at the tips. From Messrs. Wm. Paul and Son.

BUDDLEIA VARIABILIS.—A distinct and beautiful shrub of which only small flowering sprays were shown. In these the soft lilac-blue flowers were produced in dense clusters on a long spicate raceme. From Messrs. Wm. Paul and Son.

CARNATION LADY SOPHIE.—This, said to be a perpetual flowering variety, bears handsome blooms of a clear rose-scarlet. From Mr. F. Tapper, Sundridge Park, Kent.

CARNATION ISINGLASS.—The finest scarlet Carnation we have seen for a long time, the flowers very large, full and handsome, crimson-scarlet in colour. The petals are like leather, so substantial are they. It is a non-burster and of vigorous growth. From Mr. T. B. Haywood, Woodhatch Lodge, Reigate (gardener, Mr. Salter).

ARUNDINARIA VEITCHI.—This is a large-leaved, low-growing and compact kind, though evidently a good, if not indeed a rampant, grower when in a suitable position and soil. It is scarcely 2 feet high, the leaves each about 8 inches long and the leaf sheaths bristling with hairs. From Messrs. Jas. Veitch and Sons, Chelsea.

PHYLLOSTACHYS CASTILLONIS.—This is one of the most valuable and elegant of this beautiful genus, the real effect of which cannot be determined in the Drill Hall. As shown it is a most elegant bush with lance-shaped leaves, each about 6 inches long and striped with creamy white. From Messrs. Veitch and Sons, Chelsea.

PHYLLOSTACHYS FULVA.—A new species from Japan and certainly a most beautiful form. The habit is elegant, the somewhat one-sided or flat-spreading branches attaining to 7 feet or more high. From Mr. A. B. Freeman-Mitford.

ARUNDINARIA ARISTATA.—This is another elegant and beautiful kind, attaining fully 8 feet high, with branching plumes—a most attractive plant. From Mr. A. B. Freeman-Mitford.

ARUNDINARIA METALLICA.—A new species from Northern Japan, somewhat in the way of *A. Veitchi*, though generally bolder and taller in growth. It also possesses greater hardiness and is unaffected by winter cold, which causes *A. Veitchi* to brown and curl up at the margin of the old leaves. Broadly, therefore, it may be regarded as an improved *A. Veitchi*. From Mr. B. Freeman-Mitford.

PELARGONIUM ACHIEVEMENT.—This is one of the Ivy-leaved section, a fact, however, more apparent in the flowers than in the foliage; indeed, the soft, rather downy character of the

leaves, which also have a slight zone of colour, would suggest a mixture of the zonal Pelargonium. The flowers are not unlike in colour those of *Souv. de Chas. Turner*, and therefore of a showy character. From Mr. H. J. Jones, Hither Green, Lewisham.

On befitting the occasion, one of the attractions of this meeting was the splendid collections of Bamboos brought together by Mr. A. B. Freeman-Mitford and the Messrs. Veitch and Sons, Mr. Gauntlett also contributing some splendid examples of rare and beautiful kinds. The collection of these plants from Mr. A. B. Freeman-Mitford (gardener, Mr. J. Garrett) was, however, a most extensive as well as comprehensive one, many of these in large pots reaching to 15 feet or more in height. The group was of infinite interest, not less so from the fact that it contained several kinds not previously seen at any exhibition, while a few not hardy at Batsford were so labelled that no false impression concerning them could gain ground. The entire collection was in the best possible health and many of the examples in good specimen form. As a whole, therefore, this group may be considered unique. Among the varieties of *Phyllostachys* we noted *P. nigra*, *P. nobilis*, a well-named kind that when established attains 20 feet or 30 feet high; *P. Quiloi*, *P. Boryana*, *P. Henonis*, perhaps one of the gems of this excellent race; *P. flexuosa*, a well-named and distinct kind; *P. mitis*, *P. ruscifolia*, a dwarf plant, quite distinct, though less beautiful than the majority; *P. fulva*, a new species, &c. Then among *Arundinarias* we remarked *A. cristata*, a most elegant form, 7 feet high; *A. auricoma*, with golden striped foliage; *A. racemosa*, with rich graceful plumage, not previously exhibited; *A. metallica*, a promising kind in the way of *A. Veitchi*; *A. pygmaea* and a seedling plant of *A. Leydekeri*, which, though scarcely an inch high and occupying a 2½-inch pot, was replete with interest from the fact that it has been raised from seed saved at Batsford in the open, a position in the Cotswolds some 750 feet above sea-level. The Bamboos included *B. disticha*, *B. angustifolia*, *B. quadrangularis*, *B. marmorata* and others. Among those labelled as not hardy in Mr. Mitford's garden are *Arundinaria falcata* and *A. Falconeri*, the latter a singularly elegant species with spreading habit. This unique collection received the gold medal of the society. Another beautiful collection of Bamboos came from Messrs. Veitch and Sons, Chelsea, and included many fine things, the most telling being *Bambusa marmorata*, *B. palmata*, *B. disticha*, *B. Alphonse Karc*, *B. Nagashima*, &c., while of the *Arundinarias* there were *A. nitida*, *A. Hindsii*, *A. Simonsi*, a fine plant 15 feet high, *A. japonica*, &c., the *Phyllostachys* including such as *P. nigra*, *P. viridis glaucescens*, *P. Ragamowski*, *P. Henonis*, *P. Castillonis*, *P. Kumasasa*, and others of equal interest (silver-gilt Flora medal). Another set of these came from Mr. T. S. Ware, Tottenham, and here we noted *Bambusa tessellata*, *B. pygmaea*, *B. Nagashima*, *B. palmata*, *B. quadrangularis*, &c., the best *Phyllostachys* being *P. violascens*, *P. aurea*, *P. Castillonis*, *P. nigra*, *P. verticillata*, &c., for which a silver Banksian medal was awarded. Another lot came from Mr. V. N. Gauntlett, Redruth, Cornwall, who had examples of several kinds that towered to 25 feet high. These, however, were either cut or lifted pieces, and included such as *Arundinaria nobilis*, *A. Simonsi*, both giant growths, *A. Falconeri*, &c., with *Phyllostachys sulphurea*, *P. nigra*, *P. aurea* and others (silver Banksian medal).

A very pleasing circular group of *Caladiums* in many of the leading kinds came from Mr. R. Hoffman, Thurlow Lodge, West Dulwich, the plants compact, well grown and coloured (silver Flora medal). (Cut Roses from Messrs. W. Paul and Son, Waltham Cross, were again a feature, attracting much attention both by their numbers and variety. The blooms for the most part were shown in large masses in circular baskets or the like, that displayed their merits to advantage. Among the prominent kinds, *Enchantress* is ever to the front. This kind has been present at ever

meeting for weeks past, and is now as good as ever. Other good sorts were *La France*, *Mme. Joseph Bonnaire*, a fine pink; *Lady Mary Fitzwilliam*, *Mme. Jules Grolez*, a beautiful rosy peach, the buds long and well formed, the petals recurving deeply and giving it a most distinct appearance; *Marquise Litta*, *Belle Siebrecht*, *Marquis of Salisbury*, *Souv. de Lady Ashburton* (Tea), yellow and rose; *Perle d'Or*, *Souv. de C. Guillot*, dark red and orange; *Captain Christy*, *Camoens*, *Louis van Houtte*, fine crimson, &c. (silver Flora medal). Several boxes of Rose blooms came also from Mr. C. J. Grahame, Leatherhead, and here the flowers of *Comtesse de Nadaillac* were especially good, some of them among the best we have seen this season, while *Maman Cochet*, *Mrs. John Laing*, *Alfred Colomb*, *Prince Camille de Rohan*, and *Horace Vernet* were all of merit (silver Banksian medal). A fine collection of Cacti from Messrs. Cannell and Sons contained a remarkable assortment of these beautiful, singular subjects, some of them exceedingly minute, others very striking or picturesque. Among the latter may be counted *Pilocereus senilis*, with a sort of silken or hoary beard, completely enveloping the plant. The group was replete with *Opuntias*, *Gasterias*, *Haworthias*, and others, all in excellent condition (silver Flora medal). From Edmonton Mr. H. B. May again brought an assortment of beautiful Ferns, composed on this occasion of some 100 species and varieties of *Pteris*, one of the most useful groups for decoration. Some of the more distinct and beautiful are *P. serrulata plumosa*, *P. s. fastigiata*, *P. s. Applebyana*, *P. incisa*, *P. Victoria*, *P. leptophylla*, *P. tremula Smithiana*, *P. t. faecida*, *P. t. concinna*, *P. Wimsettiana minor*, and *P. Regina corymbosa*, groups of *Bouvardia* (Queen of Roses) and *B. jasminoides* occupying the ends. A fine basket of Carnation Countess of Newark, a clove-scented kind with crimson flowers, was also shown (silver-gilt Banksian). The Messrs. Dobbie and Co., Rothesay, had an extensive arrangement of cut flowers, especially of Tufted Pansies, Sweet Peas, and hardy flowers generally. Among the perennials were the double white *Campion* (*Lychnis vespertina plena*), pure white and fragrant as a Pink; *Gaillardia grandiflora maxima* (very fine), *Eryngium amethystinum*, *Scabiosa caucasica* and *alba* (both charming plants for the border or for cutting), *Lychnis chalcedonica*, *Achillea The Pearl*, *Sidalcea malvaeflora Listeri* with pink blossoms deeply fringed, *Campanula pyramidalis*, &c. Sweet Peas were beautiful and very numerous and Tufted Pansies abundant, though we have seen them shown in much fresher condition by the same firm. Annuals were delightful. Among *Godetias*, *G. Duchess of Albany*, a pure white, was very fine, a similar remark applying to the white and yellow *Sultans* (silver Flora medal). The Messrs. Wallace and Co., Colchester, again brought a splendid assortment of the best Lilies in season, such as *L. speciosum album novum*, the grandest of the white forms of *speciosum*, *L. dalmaticum*, *L. pardalinum*, *L. excelsum*, *L. Henryi*, *L. Humboldtii magnificum* (a really splendid form), *L. odorum* with trumpet blossoms of a creamy hue, irregularly blotched on the outside, the more beautiful and refined *L. Browni*, with chocolate exterior and white within; *Watsonia O'Brieni*, *Michaëxia campanuloides*, *Alstroemerias*, *Hemerocallis aurantiaca major*, many *Brodias* and *Calochorti*, *Calla alba maculata*, and good batches of such Carnations as *Mrs. Muir*, *Ketton Rose*, *Duchess of Fife*, *Mrs. Audrey Campbell*, &c. (silver Banksian medal). Hardy cut flowers were well shown by Mr. Maurice Pritchard, Christchurch, who had fine bunches of *Platycodon grandiflorum* and *P. g. pallidum*, *Spiraea gigantea*, *S. Aruncus*, *S. palmata*, *S. palmata alba*, *Montbretia crocosmiflora*, *Dianthus Napoleon III.*, *Menziesia polifolia alba*, *Delphinium belladonna*, *Lilium chalcedonicum*, *Scabiosa caucasica alba*, *Gentiana tibetica*, a greenish white flower, very large truss; *Zygadenus elegans*, a curious little plant, several good *Phloxes*, handsome fruiting branches of the scarlet *Elder*, *Sambucus*

racemosa, a splendid tuft of *Astilbe Silver Sheaf*, a very handsome and striking plant of erect habit and with plume-like panicles of buff-white blossoms. The most striking plant, however, was *Campanula mirabilis*, recently certificated. The example now shown by Mr. Pritchard was a highly creditable one, being almost 15 inches high and forming a perfect pyramid of delightful pale blue blossoms (silver Banksian medal). A small collection of hardy things from Mr. A. Perry, Winchmore Hill, included *Geum montanum*, *Inula ensifolia*, *Itea virginica*, *Helenium pumilum magnificum*, *H. grandicephalum*, very fine; *Chrysanthemum maximum magnificum*, and the pretty little *Amaryllid*, *Placea ornata*, a small white flower, with scarlet lines running down the segments. Messrs. A. W. Young and Co., Stevenage, also brought a mixed arrangement of cut flowers, such things as *Sweet Williams* and *Gaillardias* predominating. Several *Campanulas* were also shown, especially *C. carpatia alba* and the double white, *C. persicifolia alba plena*. These with *Coreopsis* and the early *Aster*, *A. Bigelowi*, were the most noticeable things.

Hardy flowers as usual came from Messrs. Barr and Sons, Covent Garden, who staged a somewhat comprehensive mixed group of, for the most part, showy subjects. In this group *Iris Kämpferi* was largely shown, the white and rich purple shades being conspicuous. Several charming plants in flower of the lovely *Romneya Coulteri* attracted much attention, as did also the improved form of *Heuchera sanguinea* called *grandiflora*. *Boceonia cordata earnea* is distinct, and the creamy white *Astilbe Thunbergi Backhousiana* is very pretty. *Phloxes*, *Gaillardias*, *Potentillas*, and varieties of *Chrysanthemum maximum* were shown in plenty, likewise *Coronilla varia*, other pretty things being *Atragene alpina*, *Jasione perennis*, with *Phyteuma*-like heads of blue, *Platycodon Mariesi*, &c. (silver Banksian medal). Hardy flowers were also set up by Mr. T. S. Ware, Tottenham. In this group were many beautiful Lilies, such as *parvum*, *auratum vittatum* and a *platyphyllum*, *Humboldtii*, the richly-coloured *nepalense*, *Browni* and *odorum* in plenty, so that the relative merits of each could easily be seen, *dalmaticum*, *giganteum*, with several huge pendent white flowers, *Bloomerianum*, *magnificum*, &c. Quite a host of the best border Carnations was shown in bunches, and a few perennials, most of which have, however, been mentioned, save *Alstroemeria pelagrina alba* and *Argemone hispida*, with handsome white Poppy-like flowers. The Messrs. Cutbush likewise had hardy flowers mingled with Carnations of the border and Malmaison sections, the whole arranged as an undulating bank. Of the former, *Campanula lactiflora*, a very showy plant with immense panicles of blue, also *C. carpatia alba*, *Francoa appendiculata*, *Campanula persicifolia coronata alba* were noticeable. In border Carnations, *Santiago*, buff-yellow, *S. G. Brooks*, fine yellow ground, *Mary Morris*, *Isla*, *Voltaire*, *Mrs. Eric Hambro*, and others were noted, while *Princess of Wales* and the bush kind well represented the Malmaisons (silver Banksian medal). A fine collection of Carnations came from Messrs. James Veitch and Sons, and contained all the best kinds in commerce. Among the whites, *George Macquay* and *Miss E. Terry* were especially good, the former of fine form and substance; *Little John*, scarlet, *Cardinal Wolsey*, fancy, *Her Grace*, *Sea gull*, *Pandelli Randi*, and *Lady Ridley* being among the best in a numerous set. The same firm contributed a fine bank of annuals, such things as *Malope grandiflora* and *Lavatera trimestris*, in many exquisite shades, being most conspicuous. *Stock Princess Alice*, pure snow white, is grand. *Shirley Poppies* of an excellent strain, *Clarkias*, *Eschscholtzia crocea alba*, *Leptosyne maritima*, *Chrysanthemum Burridgianum*, and others were also shown in excellent and attractive bunches. Sweet Peas were also numerous and good (silver Banksian medal). Messrs. Sander and Co., St. Allans, had a group of *Acalyphas*, in which A.

Sanderiana (syn., *A. hispida*) was prominent, *A. Godseffiana* being also shown; the new *Palm*, *Licuala Jeaneneyi*, and *Caladium Ami Schwartz* were also included, while *Fourcroya Watsoniana*, with handsome silver-lined leaves each 2 feet long, was very telling as an isolated example. The Messrs. Carter and Co., High Holborn, had a most extensive assortment of Sweet Peas, of which the most noticeable were Countess of Powis, bronze-pink, Grey Friar, Little Dorrit, Splendour, Mrs. Joseph Chamberlain, Meteor, Her Majesty, Primrose, The Bride, Katherine Tracey, Mrs. Eekford, and Salopian. A smaller group of novelties came from Mr. Eekford, Wem, Salop, who put up bunches of *H. F. Bouverie*, pink and white; *Mrs. Dugdale*, rose; *Sadie Burpee*, white; *Duchess of Westminster*, buff-pink; and *Robert Hood*, dark crimson-amaranth. Several lovely Water Lilies were shown by Mr. Jas. Hudson, gardener to Mr. Leopold de Rothschild, Gunnersbury House, Acton, the most notable of which are already given. Other excellent things, however, were *Nymphaea tuberosa* sp., pure white and very large, with conspicuous yellow centre and giant leaves nearly 18 inches across, which without flowers are exceedingly handsome, and *N. sanguinea*, a rather small, but richly coloured flower. Mr. F. W. Campion, Colley Manor, Reigate (gardener, Mr. J. Fitt), brought some three dozen bunches of *Rose Crim-son Rambler*.

Fruit Committee.

New Strawberries and Melons were plentiful, but few awards were given. Messrs. Veitch and Sons had a fine lot of Gooseberries in pots, also Nectarines and Currants, with fine fruits of gathered Cherries and Strawberries. Vegetables also were shown in quantity, Peas being of great merit.

First-class certificates were given to the following:—

CHERRY EARLY RIVERS.—This has been many years in commerce, but never certificated. It is a splendid black fruit, early, and very richly flavoured. From Messrs. Rivers and Son, Sawbridgeworth.

PLUM EARLY TRANSPARENT GAGE.—A well-known large, round Plum of a greenish colour, with crimson spots, flesh firm, juicy, and of excellent flavour. It is a free bearer. From Messrs. Rivers and Son.

Awards of merit were given to the following:—

STRAWBERRY LADY SUFFIELD.—A medium sized fruit with dark red, firm flesh. The shape is conical, not unlike that of *Lord Suffield*, the flavour being very rich and distinct. From Mr. Allan, Gunton Park, Norwich.

RASPBERRY GOLDEN QUEEN.—A seedling between Raspberry Superlative and *Rubus laciniatus*. It is a large yellow fruit, freely borne, and of good flavour. From Messrs. Veitch and Sons, Chelsea.

A remarkably fine collection of Gooseberries, trained trees, nearly 100 in all, came from Messrs. Veitch, Lim., Chelsea. The trees were laden with fruit. Here could be seen the cream of the varieties. Among the reds, *Clayton Beauty*, *Duke*, *Forester*, *Speedwell*, and *Napoleon le Grand* were very fine, *Gipsy Queen*, *Hue and Cry*, *Pilot*, and *Trumpeter* being the most noticeable among the yellows. There was less variety in the green section, *Matchless* and *Surprise* being good, with excellent trees of *Freedom*, *Mitre*, and *Progress* in the white varieties, the small dessert section also being well represented. Some half-dozen varieties of Currant trees in pots were staged, the best being *Mammoth*, *Warner's Grape*, *White Dutch*, *Red Dutch*, and *Ruby Castle*, with trees of *Precoce de Cronceels Nectarine*. The same firm had another exhibit of gathered fruits in another part of the hall, including large baskets of *Veitch's Perfection*, *Latest of All*, *Bicton Pine*, *Frogmore*, *Loxford Hall*, *Oxonian*, *Lord Suffield*, and *Waterloo Strawberries*, with *Cherries* of well-

known kinds (silver-gilt Knightian medal). Messrs. T. Rivers and Son, Sawbridgeworth, sent a small, but remarkable collection of fruit, including splendid *Belgian Purple* and *Transparent Gage Plums*, *May Duke*, *Bigarreau Napoleon* (immense fruit), *Ludwig Bigarreau*, *Bigarreau de Schrecken*, *Savés de Burr*, *Hâtive de Boulbon*, and *White Bigarreau Cherries* (silver Banksian medal). Messrs. Laxton Brothers, Bedford, sent a new *Strawberry Trafalgar*, a large, nice-looking fruit, the result of crossing *Elton* with *Waterloo*, but the fruits were too soft in the committee's estimation. Very heavy fruiting plants of their new *Fillbasket* were sent. This is an enormous cropper. Mr. Allan sent *Lord Suffield Strawberry* to show its late fruiting qualities, also a new *Melon*, *Gunton Seedling*. From the *Royal Gardens*, *Frogmore*, Mr. Thomas sent eight large fruits of a *Melon* named *Lord Edward Cavendish*, but lacking flavour. Mr. Carmichael, Pitt Street, Edinburgh, sent his new *Strawberries*, *Princess of Wales*, *Britannia*, *Queen of Denmark*, and *Richard Gilbert*, but these were not considered any advance on existing varieties. Mr. Divers, *Belvoir Castle Gardens*, *Grantham*, received a cultural commendation for very fine *Strawberries*, the varieties being *Dr. Hogg*, *Waterloo*, and *Gunton Park*. A new *Raspberry*, named *Old Gold*, was sent by Mr. Maher, *Vatendon Court*, *Newbury*, but the fruits were all smashed in transit. Mr. Becker, *Jersey*, sent *Red Currant Comet* and a new *Gooseberry*, *Trouville Giant*. The *Currant* sent was thought to be very like *La Versailles*. Mr. Eekford, Wem, Salop, sent some half-dozen varieties of Peas. *Monarch* was a very good 2-foot variety; *Rex*, 5 feet; *Philip Crowley*, 5 feet; *Wem*, 5 feet; and *Consummate*, 2 feet. All were desired to be sent to *Chiswick* for trial. Messrs. W. W. Johnson, Boston, Lincoln, sent fifty dishes of Peas, excellent in every way. *Critic*, *Prince Edward*, *Royal Jubilee*, *Late Queen*, *Conqueror*, *Duchess*, *Ebor*, *Prolific Marrowfat*, *John Howard*, and *Memorial* were the best (silver Banksian medal).

Meeting at Chiswick.—The fruit committee met at Chiswick on the 22nd to examine the Peas and Potatoes. Out of some thirty stocks of early varieties of Potatoes only four received favourable notice by the committee. These were cooked to test flavour, but the tubers were not ripe. *Leader*, from Mr. Myers; *Ninetyfold*, from Messrs. Sutton; *Pirremont Seedling* and *McKinley's* were the varieties tried. These are to be given another trial to test quality early next month. The committee examined a new *Lettuce* named *Crystal Cabbage*. This was given an award of merit on July 5, and not a single plant had run since then. It is a very fine type, hearts firm and sweet. It was now recommended for a first-class certificate as a valuable summer *Lettuce*. It is of the *Neapolitan* type, leaves slightly fringed and tipped with brown.

The following awards of merit were recommended and confirmed on the 26th:—

TURNIP NEW MODEL.—A very shapely root, flesh white and solid. It is a good summer variety, not unlike *Snowball*, but with a longer tap root. It has a rather large top and is above medium size. From Messrs. Watkins and Simpson.

PEA THE BRUCE.—This is a 5-foot Marrow Pea, pods very large and freely produced. It is a very fine mid-season variety. From Mr. Eekford, Wem, Salop.

PEA PRIOR.—A 4-foot variety with deep green large pods of splendid quality. It is a very free cropper, the pods being produced in pairs to the bottom of the haulm. From Mr. Eekford.

PEA CONTINITY.—A late and heavy cropping Pea, the pods mostly borne in pairs and of a deep green colour. It has a rich Marrow flavour, and is one of the best dry weather Peas grown at Chiswick. From Messrs. Sutton and Sons, Reading.

PEA HARTFORD'S SUCCESS.—A 3-foot variety of strong growth, having medium-sized pods well filled with deep green Peas, with a distinct

Marrow flavour. From Messrs. Nutting and Sons, Southwark Street, London, S.E.

PEA MANSHIELD SHOW.—A very fine 3-foot Marrow, pod very full and of a beautiful colour. It is an enormous cropper and an excellent main crop variety. From Messrs. Wright Brothers, Mansfields, Notts.

PEA HONEYDEW.—A 2-foot Marrow variety. It is a mid-season Pea, pod large with seven to nine Peas of a deep green, and excellent in quality. It is a strong grower and very prolific. From Mr. Sims, Fyvie, Aberdeen, N.B.

PEA SUGARINE.—A 4-foot variety, pods of medium size and well filled with Peas of remarkably fine flavour of the *No Plus Ultra* character. It is a splendid cropper and a free grower. From Mr. Sims.

BOOKS.

PANSIES, VIOLAS AND VIOLETS.*

This is one of "Dobbie's Horticultural Hand-books," edited by Mr. W. Cuthbertson, F.R.H.S., and a very feeble production on a very interesting subject which worthily treated might form a charming book. It begins with a "historical introduction" by the editor, in which he assumes that the Pansy, cultivated as we know it, is simply *Viola tricolor*, and he thinks that earlier than the present century there seems to have been no effort made to develop that wild plant beyond "the superior cultivation which would naturally follow transference from the field to the garden." Now, transferring *Viola tricolor* from the field to the garden would make very little change in it indeed; and, a good many years before, Shakespeare spoke of "Pansies streaked with jet," which could not arise by simply transferring the common little field *Viola* to the garden. We may tell Mr. Cuthbertson that botanists of the highest mark and knowledge of living plants, like the late T. Boswell Syme, did not take that view of the origin of the Pansy. Passing over the origin of the Pansy in this way, of course the author does not touch upon such interesting questions as the origin of the *Neapolitan Violet* as distinct from the varieties of *Viola odorata*. There is a chapter on the botany of the Pansy in which all sorts of subtle things, useless from a garden point of view, are gone into, but no description is given of the many interesting wild species of "Viola" which adorn the mountains of the northern world, Europe, North and South America and Asia, some of the most beautiful being wholly omitted from the book, like our beloved *Bird's-foot Violet*.

With this neglect of the wild species of "Viola" there is also neglect of the improved races of Pansies, such as the beautiful kinds that come to us from Luneberg, in Germany, which are among the most refined and delightful in colour of all. The use of Tufted Pansies in rock gardens is not mentioned, though we think this is the most important of all their uses: also the important fact, probably not known to the author, that in the southern counties, where the Pansy is so apt to die off in hot summers and from various causes, it can be successfully cultivated on stone walls. Much prominence is given to what is called the "fancy" and other ugly and useless Pansies, which are only of the slightest importance except to those who show their flowers at exhibitions. Naturally, much notice is taken of the Pansy for exhibition, though it only concerns a few people who generally give each other prizes. Taking no notice of the beautiful members of the genus, naturally the book conforms to the ignorant use of the word "Viola" as applied to garden varieties, and says the term *Viola* "has done duty for years without much, if any, inconvenience," and this in the face of the perennial farce of the gardener having to explain to the lady the differ-

*"Pansies, Violas and Violets." (Macmillan and Co., London.)

ence between Pansies and Violas. Then the author goes on to explain the difference himself in the following way:—

Violas, as distinct from Pansies, are much more floriferous; most of them are more compact in habit and more perennial in their nature, and consequently much better adapted for bedding. Their blossoms are often sweetly scented; they never have blotches similar to Pansies, and they are generally more elongated than round in their form.

There is scarcely a line of the above which is not open to objection, and the author takes no account of the rule of the botanists as to nomenclature, or of the fact that the genus contains no less than 300 to 400 species adorning the mountains, prairies, and woods of the world, or of the fact that these so-called Violas of his are just as much hybrids as the common Pansies, and should be classed as such, as they were indeed so classed by their earlier raisers, who called them "bedding Pansies."

The art of wiring the unhappy Pansies is explained, but nothing said about simpler and more artistic ways of using the Pansy in the house.

Each individual flower should have a fine wire carried alongside the stalk, the other end being pushed into the spur or calyx; sometimes the wire is hooked at the top and made to catch over the bend at the top of the flower-stalk. The wire is bound gently to the flower-stalk by means of a piece of knitting cotton or wool soaked in water. This much being done, no great difficulty will be experienced in making the blooms into a spray, and working in among them some small pieces of foliage. The best way to learn the process is to get a well-made spray from an exhibitor after a show and take it home, and take it carefully to pieces and remake it—or, what is better still, get a practical lesson from a lady or gentleman who is an expert! [The italics are ours, as it is funny to think of a lady or gentleman wiring a Pansy!]

A child who gathered a bunch and put it in its mug would do far better. But the delusion of all these exhibiting people is to mistake themselves for the world, which has too long put up with their absurdities. Nor can we look for much light from them for the garden and its lovers. Even from their own point of view their ways are stupid, as the wired Pansies at their shows, crucified as they are on their little stands, wither up in a few hours, even when water is thrown over them by an attendant, as might have been seen in many instances at the Crystal Palace show. But when one of them writes a book on the subject for public use, we have the right to expect something better than this, and one in which the large natural genus "Viola" should be described, at least so far as the wild species have any claims to beauty.

NOTES OF THE WEEK.

Ivy-leaved Pelargonium Galilee is perhaps one of the showiest in this very useful group, the flower-trusses abundant and large and the warm rosy-pink shade very attractive.

Carnation Mrs. Frank Watts.—Though an old variety this is still a fairly good one, surpassing in some respects other whites of more recent date, and as a dwarf bedding white it is most useful. The flowers are not of the largest size.

Rose Her Majesty.—Quite recently in a riverside garden we noted this handsome Rose doing well as a standard, the tree having been planted some two years ago. The blossoms were very handsome and large; indeed, both for size and colour these were of the finest possible description, creating a rich display as the huge flowers spread out to their full size.

Fuchsia Ballet Girl.—This free-flowering kind appears one of the best of the double white varieties—that is to say, the corolla is double and very pure white, the sepals being of a rich decided scarlet. So far as the habit is concerned, this leaves but room for small improvement, and the growth generally being compact, a first-rate habited plant is the result.

Verbena Ellen Willmott is one of the largest of the pink kinds, the trusses of fine form, the pips individually large, making up a very showy head of

bloom. Several beds of this new kind may now be seen in Messrs. Veitch's nursery at Chelsea approaching to perfection. In a few days a sheet of bloom will result.

Oenothera speciosa is now one of the showiest of the Evening Primroses, valuable indeed from the fact that it is a good perennial, as also a free and profuse bloomer. The large handsome flowers are at first nearly pure white, changing, however, to a soft or delicate rose shade as they advance to maturity, thus producing a very pretty effect where large groups exist in the garden.

Carnation Alice Ayres.—Had this been a self-coloured variety, either white, scarlet, or crimson, it would have taken a deal of beating—at least from the point of view of free flowering. In a very large collection of border kinds this well-known striped Carnation surpassed the majority of both old and new sorts by the great mass of expanded flowers open at one time—an undoubted recommendation where such things are freely employed.

Carnation Raby Castle.—Where a good, useful, hardy and free-flowering pink Carnation is required for the garden, this old and well-known variety is still of much value, and this in spite of the deep saw-edged petals. It is not affected by the sun when planted in exposed parts of the garden. The way that some kinds suffer in this respect, e.g., Duchess of Fife, robs them of much of their value unless it be in positions where the sun does not reach the plants.

Aquilegia Stuarti.—Dr. Stuart's hybrid Columbine is not often seen in good health and often fails to establish itself in gardens. When in Ireland in June I saw some very pretty plants of this Aquilegia, but none equalled about half a dozen, seen shortly before, growing in the gardens at Cavens, Dumfries, N.B. The plants were large and produced freely the exquisitely coloured flowers one so much admires.—S. ARNOTT.

Erigeron mucronatus.—The true Erigeron mucronatus of Mexico is, I believe, quite different from the *Vittadenia triloba* (*V. australis*), the well-known Australian and New Zealand plant to which "S. W. F." evidently refers on p. 69 (July 23), and which is usually and more correctly known as the New Holland Daisy. If "S. W. F." is really referring to the true Mexican Daisy (*Erigeron mucronatus* of De C.), I shall be glad of a specimen.—F. W. B.

Neitera depressa.—This is one of those interesting plants whose blooms are rarely seen; yet when the flowering is past and the fruits begin to show colour it is quite another plant, the dense dwarf carpet of leaves transformed to a bed of orange-scarlet. It is then that the plant attracts attention, for the berries remain in good colour for a very considerable time. As a pot plant in the greenhouse when the fruits are ripe the plant finds many admirers.

Martagon Lilies at Kirkconnel, Newabbey, N.B.—The old double Martagon Lily has been grown for many years in the interesting garden at Kirkconnel, and it is seldom that one sees it in such quantity or doing so well. Other forms are also grown, and *L. Martagon* var. *dalmaticum* is growing very vigorously and promises to be even more at home than the others. One fine plant was very beautiful, the round ball-like buds being beautifully coloured and covered with a snow-like tomentum.—S. ARNOTT.

The old Roses at Kirkconnel, N.B.—Last week I had again the pleasure of seeing the old garden Roses at Kirkconnel, Newabbey, N.B., of which Mrs. Maxwell-Witham gave an interesting account in THE GARDEN some years ago. Some were nearly over, but the great bushes of many were very beautiful with their bright and fragrant flowers produced in almost endless numbers. Very beautiful was one known at Kirkconnel as Swiss Boy. Its graceful habit and crowds of pale pink or blush flowers deliciously fragrant made it quite a feature.—S. ARNOTT.

Begonia Fairy Queen.—This is one of the hybrid semperflorens class, and a charming plant either for pots or for the flower garden. The sturdy, compact growth is not more than a foot above the pot, and furnished with half a dozen main branches besides numerous laterals, with not a stick or tie among the dozens of plants seen. It is indeed an ideal type, wherein fine habit and free flowering are combined. It is one of the many charming things which have originated with the Messrs. Sutton, of Reading.

Two beautiful bog plants.—Herewith I have pleasure in sending you a bunch each of

Pyrola rotundifolia and *Epipactis palustris*, both of which are growing here in our sandhills in the greatest profusion. I have never seen them so fine. They grow in rather wet places between the sandhills. At present the whole place is full of them. The *Epipactis* does best among the tall grass, while the *Pyrola* likes a somewhat exposed position, in some places covering many square yards.—W. H. STANSFIELD, *Southport*.

Abutilon Golden Fleece.—For its free flowering as much as for its colour this is perhaps one of the best kinds ever raised. Several varieties may be noted for freedom of flowering, but they cannot compare with the above in the continued display of blossoms, with no apparent diminution in size and no apparent distress from the great number already borne. Planted out in the conservatory, where a little freedom of growth can be given, it is one of the showiest of flowering plants for months in succession.

Tufted Pansy A. J. Rowberry, seedlings from.—During the last few days several promising seedlings from this rich yellow rayless variety have been in particularly good form. Unlike many other Tufted Pansies, flowers of this colour and texture appear to revel in the somewhat heavy and sunless weather which has prevailed in the suburbs, and the blossoms, which during bright weather often get scorched and blistered, have been almost free from this blemish and have formed a welcome contrast to those of other varieties now flowering freely.—D. B. C.

Plagiatus grandiflorus.—Some experience difficulty in retaining this singular-looking rayless composite in their gardens. In the garden of Captain Stewart, of Shambellie, Newabbey, N.B., it is doing well, and appears to stand the prevailing drought better than many other plants. It is also known as *Balsamita grandiflora*, but as *Plagiatus* is now merged in *Chrysanthemum*, one is at a loss to know its specific name in the *Chrysanthemums*, unless it is *C. grandiflorum*—not, of course, the plant usually grown under that name, but *Wildenow's grandiflorum* from Northern Africa.—S. ARNOTT.

Pentstemon lævigatus.—This distinct hardy Pentstemon is at present in full bloom in the garden of Mrs. Maxwell-Witham at Kirkconnel, Newabbey, N.B. It was received under the name of *P. digitalis*, but I find on reference to the "Index Kewensis" that the latter has been superseded by Aiton's name of *lævigatus*. *P. digitalis* is Nuttall's specific name, and is not inappropriate, the long spike of whitish flowers being not unlike that of a small Foxglove. At Kirkconnel this Pentstemon grows about 2 feet high and is quite hardy. So distinct a species is deserving of being more largely grown.—S. ARNOTT.

The Flame Flower (*Tropæolum speciosum*).—Those who think this brilliant plant will only grow in moist soil or in shade should see it in Captain Stewart's garden at Shambellie, Newabbey, N.B. The garden is dry, and here the Flame Flower becomes a weed and has to be cleared out as opportunity offers. Among the Gooseberry bushes it becomes rampant, and in a bed of Ferns it disfigures the fronds by preventing them from expanding in their usual way. Pretty effects are, however, at times made by its efforts to ascend by means of other plants. One of these is shown on a good plant of *Cimicifuga dahurica*, up which it has climbed, the brilliant flowers of the *Tropæolum* being charming when seen with the creamy white plumes of the supporting plant. The more one knows of the *Tropæolum* the more he inclines to the opinion that in even dry soil it can be induced to grow provided it can once obtain a firm hold. When it begins to run underground it soon makes headway and grows rapidly.—S. ARNOTT.

Names of plants.—*C. L.*—*Lycium barbarum*.—*Mrs. C. Boyd.*—*Epipactis palustris*.—*J. R.*—*Pteris cretica albo-lineata*.

THE MARKET GARDEN.

KENTISH FRUIT CROPS.

CURRENTS.

THE extensiveness of the Kentish fruit industry is apparent right through the county from the time that green Gooseberries find their way into the market till the Apples and Pears have been disposed of. At every railway station in fruit districts are to be seen piles of round baskets, full and empty. Not only is the fruit carried by special trains, but the ordinary passenger traffic is augmented by fruit vans. In addition to the piles of round baskets, wooden tubs and earthenware vessels pass backwards and forwards from fruit field to market, showing that trade in soft fruits is now approaching its height. Writing at the beginning of August, some fruits have to a great extent been disposed of. Fields that a few weeks ago were red with Strawberries now present a somewhat bare and untidy appearance, and so they will have to remain till the rush of other work is over and they can be put in order ready for another season. Early Cherry trees have been stripped and many Gooseberry plantations have been picked over for the last time, and tubs and jars are now in demand to convey Currants and Raspberries to market. Both these fruits have their favoured localities, though the cultivation of the former is more generally distributed, and it is to the Currant crop that I shall confine my present remarks.

Though Currants, Red, Black and White, are grown in every garden of any pretensions in the kingdom, it is in Kent that they are treated as a commercial crop, and Kentish fruit in a raw or preserved form finds its way to all parts of the country. Black Currants in localities where they succeed are among the most profitable crops cultivated by Kentish fruit growers. Every season shows a demand for this luscious fruit, and generally prices run high. It is

rather too early at the time of writing to speak of the state of the markets this season, but everywhere there is an abundant crop of splendid fruit. Cultivation does much towards the production of the finest samples, but suitability of soil and aspect do more. As Black Currants are grown everywhere, this is evidence enough that they do not require any special soil to grow and fruit moderately, but when one comes to compare berries from other districts with the best Kentish productions grown under ordinary rules of cultivation, he sees at once the advantages of soil and situation. On sloping hillsides and in fertile valleys acres of Black Currants are grown under standard Apple and Plum trees, and are looked upon by many growers as their staple crop. It does not follow that where Gooseberries and Red Currants are grown in large quantities Black Currants will also be found. It is so in some instances, but in one particular locality I am acquainted with, where the soil is a light, sandy loam and grows Gooseberries and Red Currants to perfection, it is rarely one sees a Black Currant plantation. Aware of their superior qualities for market, growers have tried them, but the result has been partial disappointment, for, in order to pay their way, bushes must not only grow and fruit freely, but they must produce berries equal to the best from other districts. This is one feature of the Kentish fruit industry. One locality has a reputation in the market for a particular kind of fruit, and it is there where salesmen look for their supplies. Thus Strawberries, Raspberries, Cherries, Gooseberries, Currants, and so forth have their own districts, and fruit produced from any other locality must be of equal quality and in sufficient quantity to merit its giving a substantial return in the market. Last year the Black Currant crop was uneven, and returns varied in consequence, though the advantage was reaped by those having a good supply of fruit, as prices ruled high. Though crops this season are generally good, growers do not fear the glut, for, unlike some other fruits, the

returns are invariably sufficient to render the crop a profitable one.

The Kentish grower has learnt his methods of cultivation in the best of schools, viz., that of long experience; and though here and there one sees the work of a dilatory farmer who holds the wrong impression that good working and systematic pruning are not of the greatest importance, yet, as a whole, the plantations are kept well worked, the bushes fed with manure, and the old wood is every season removed on an approved method to make way for the young healthy shoots from the base of the bushes which produce the finest of fruit. Baldwin is the most popular variety, though Lee's Prolific and Black Naples are also grown. When treated on the soundest principles, plantations of Black Currants last many years when grown alone or as an intermediate crop between Apple and Plum trees. With all bush fruit surface cultivation during the summer, not only to keep down weeds, but to prevent evaporation, is an important item, and all the best plantations are dug and manured in the early spring.

Black Currant growers have one dreaded enemy, which is, unfortunately, increasing, viz., the bud mite (*Phytoptus ribis*). So little is known of the life history of this pest that at present no one appears to know how to successfully combat it. In Scotland I understand Black Currants have almost ceased to be a commercial crop on account of this dreaded pest, which has only been known in Kent during recent years, where it was probably introduced through the medium of infested plants. Most growers from bitter experience are becoming alive to the presence of this enemy, though no doubt it gained headway before its presence was actually known, or anyone knew the amount of damage it is capable of doing. I am acquainted with one grower in the Isle of Sheppey who relied almost entirely on his Black Currants, and his plantation produced some of the finest fruit I have ever seen. The unnatural swelling of the buds caused him no alarm when it first appeared a few seasons ago,

as he was unaware of the cause of it, and thought a few of the buds were prematurely swelling on account of the mildness of the season. Matters grew worse, and the man naturally became alarmed; but it was too late to apply a remedy, as almost every bud became infested, and last year he was obliged to root up and burn every bush in his plantation, which is several acres in extent. The loss to him is very serious, and similar instances could be named of growers who have good reason to deplore the presence of the dreaded mite. So far no insecticide has any effect on it, and the only means of checking it appears to be that of picking off the infested buds. The spread of the enemy is doubtless caused by planting from infested stocks, and Kentish growers are already getting particular about this. Too much attention cannot be paid to the checking and eradication of the bud mite, which without doubt threatens the future of Black Currant culture as an industry in the county of Kent.

White Currants are not a market crop correctly speaking. A few are grown in some districts chiefly for sale as dessert, but the output is nothing compared to that of the Red Currants, which are now ripe and picking is in full swing. Prices are not high owing to the heavy crops. Red Currants, which are by no means so profitable as Black, are usually grown in company with Gooseberries, and form a succession to the latter in picking. The bushes last about as long as those of Gooseberries, and as soon as they show signs of decay they are grubbed up, and after the ground has been treated to a change of crop, fruit is again planted. Red Currants generally are remarkable in size and colour this season, and the only thing that growers complain of is the price. Generally growers are also raisers, and in most plantations there is a small nursery filled with young stuff to take the place of worn-out bushes as they are done away with.

Most of the fruit goes to the London markets, except that which is sold direct to the jam factors. Much has been said and written about the institution of jam factories in fruit-producing districts, so that the preserve can be made on the spot and railway and other expenses thereby dispensed with. Owing to some reason or other, however, the venture does not appear to have been attended with much success, as I know of several such factories that are given up, and the fruit from all round goes away to the jam-makers in London and elsewhere.

Growers have found out that the best way to produce heavy crops of Red Currants is to prune the bushes closely: therefore all side shoots are spurred in during the early spring and the centre of the bushes kept open to admit sunlight and air. After pruning, the bushes present a skeleton appearance, with only a few bare branches showing. Soon, however, they assume a mantle of green, and the once bare stems are wreathed with large bunches of luscious fruit. Lime is dusted on the bushes in the winter to destroy Moss growths and prevent birds from stealing the buds, and when the soil is forked over between the bushes and manure worked in, all is ready for the next season's crop. In different districts the varieties are known by local names, but among the recognised standard sorts, Red Dutch and Raby Castle are largely cultivated. Red Currants are usually grown between standard and half-standard trees in mixed plantations, and though growers generally manage to sell at paying prices, the demand is not so good as that for Black Currants.

Threading your way through the narrow, winding Kentish lanes which intersect fruit

plantations and Hop gardens for miles, one has sufficient evidence of the importance of the Currant industry to the working population.

G. H. H.

FLOWER GARDEN.

VIOLETS IN THE SOUTH OF FRANCE.

THE Violet is in flower during the entire winter—that is, from October to March—on the Mediterranean coast from Ollioules, Toulon and Hyères to Nice-la-Belle and beyond right on to Italian soil. Hyères, with its vast gardens watered abundantly by streams fed by its ancient canals or by hundreds of elevators called *norries*, by which water is lifted in enormous quantities to the surface of the soil, is of all places on the Mediterranean coast the greatest and by far the most important producer and exporter of Violets in winter. In the winter of 1897-98 the ground occupied with Violets in Hyères alone exceeded altogether 2500 acres in extent, and this will be increased in the next winter season. The temperature during the last winter having been almost always very mild, the production of Violets never failed to be abundant. The consignments of Violets by post often filled two or three vans at the Hyères railway station. Under the influence of the warm weather prolonged late into the autumn of 1897, the Rose Safrano began to flower vigorously in October, and had no buds, or almost no buds, left after December. The flowers of the Violet profited by this winter loss of the Safrano, and their price continued to be very fairly remunerative throughout the entire season, despite the more than usual abundance of the supply. If in a climate like theirs and on soil well watered and rich by nature, the Hyères growers justly consider the culture of the Violet as one of the most remunerative and least liable to accidents, it is only right to add that, generally at least, they are men of observation, knowing how to choose the most vigorous and the most productive varieties for a particular soil, as also, by planting, manuring, and cultivation, happily combined, how to make the most out of their advantages. It must be admitted that the Hyères gardeners, who for some twenty years past have made a speciality of the winter production of Violets for export, do succeed with them.

The right sort of manure applied in September, just when by the action of the rains or of artificial watering, the growth begins to appear, is applied in abundant, but rational quantities. Rich manure excites too abundant production, imparts the very long flower-stalks, and gives to the flowers their size of petal and brilliancy of hue—three qualities which, united, double the value of the Violet. Some Hyères growers of Violets plant in breadths of two to three rows, each 5 feet if three rows, and 3 feet if planted in two rows only; but the greater number—and in our opinion this is the right plan—gives greater facility for gathering. The plants, set from 10 inches to 12 inches apart in lines, are in most cases arranged in isolated tufts, which acquire size and strength in the second and third years. The plantations are seldom preserved beyond the third year. Those of the first and second year generally give, with equal advantages of manure and attention, more and finer flowers than the old plantations, and they also begin to bloom earlier. In order to obtain a good crop in the first winter season after the planting, the

planting should commence in January and be finished by the middle of March at latest.

Careful selection of plants and seeds has produced new varieties.

VARIETIES.

Twenty years ago only two varieties were cultivated at Hyères. One was an old favourite with the gardeners at La Valette, near Toulon, and for that reason was called

LA VALETTE.—Its flowers were small, of a bright violet colour, too short in the peduncles, however, but very abundant and sweetly scented. It was, moreover, vigorous and hardy. The other was, I believe, a native of Algeria, a vigorous kind, called

WILSON, the flowers of which were larger and likewise very abundant, too pale in colour, however, but long in the flower-stalk. The varieties now-a-days preferred by the Hyères specialists have happily inherited the long flower-stalk which the Wilson possessed. After this variety came the

RUSSE, or The Czar, with flowers of equal size and a fine deep violet colour, which made it deservedly popular. After that came

LUXONNE, planted in great quantity. Its flowers, of good size and a very deep violet, are very abundant. It is still cultivated to a certain extent, though much less so than

VICTORIA, which is more vigorous, very free flowering, the blooms large and well formed, and of a brilliant violet, with very long flower-stalks. This last quality in varieties which are cultivated for exportation facilitates the handling of the flowers.

Many Hyères gardeners, by making selections of Victoria and Luxonne, have obtained some varieties well worthy of being increased. All the kinds, more or less, are to be found in the Hyères nurseries, and some have been put into commerce. Among these last I recommend the following varieties:—

ABONNEN NEVEU.—A vigorous plant, producing large flowers of a brilliant violet colour with very long stems.

GLOIRE D'HYÈRES AND PRINCESSE BEATRICE.—The former was raised by M. Joseph Roux, of Hyères, and the second came from the nurseries of the late M. Recons, Sen., of Hyères. Both varieties are vigorous and bear freely large round flowers of a deep violet colour. Gloire d'Hyères is the variety whose flowers and leaves best resist the cold, which is sometimes very severe in winter.

PRINCESSE DE GALLES, from the late M. Recons' garden, is a vigorous plant and hardy, the flowers being abundant, of a deep violet colour, and the largest so far known among Violets.

The cultivation of Violets for winter export occupies from 1000 to 1500 women in gathering alone, not including other than the single-flowered varieties. In the Grasse region (Alpes-Maritimes) the double-flowered variety known as de Parme is cultivated for perfumery, and only in very insignificant quantities for exportation. All the Violets at Hyères are grown outdoors, the greater portion, however, under the protection of trellises made with the branches of the great white Palm of the Mediterranean shores, and placed straight or slanting. I think it would be found very remunerative to guard against sudden falls of temperature in winter by using frames for this purpose, which could be covered up at will with glass or matting slightly raised, and which could be rolled up in the morning and let down in the evening. Matting for this purpose is already much used among southern growers in the cultivation of many plants grown for their flowers

in winter, such as Mignonette, Carnations, Freesias, and many other bulbous plants.—
M. NARDY, SEN., in *La Semaine Horticole*.

FLOWER GARDEN NOTES.

STOCKS.—In connection with the recent remarks on the large percentage of single Stocks it is worth noting that different forms vary considerably in this matter in different seasons. August-sown East Lothians, for instance, were last year nearly half single, but this year the proportion of double to single forms is quite five to one, whilst, on the other hand, the branching white variety known as Princess Alice, always grown largely for cutting, and that, as a rule, comes very true, is throwing this year a large percentage of single flowers. Stocks may be safely put down as one of the few plants that do fairly well on dry, poor borders, that is if healthy, sturdy seedlings with plenty of roots are put out. East Lothians may be sown at any time during the present month either in boxes or in a cold frame, and as judiciously mixed they make charming summer beds, it is just as well to sow in separate colours.

PINKS.—These old-fashioned flowers have been very fine this year, and the latest are still (July 26) in full bloom with occasional buds pushing up. Ernest Ladhams is my latest, and it holds out well until plenty of Carnations are in. It has been inclined to burst this year rather earlier than usual, but the flowers are exceptionally fine. Propagation of any of the choicer kinds of Pinks it is found desirable to increase may be carried out as soon as convenient. Insert the pipings firmly in rather light, sandy soil, keep fairly moist and shade from hot sun until root-action commences.

CARNATIONS.—Mention above of the tendency to split on the part of Ernest Ladhams Pink reminds me that it may not be out of place to note the names of Carnations in flower that have shown no tendency in that direction, the sorts named having all come safely through last winter on a north-west border without any protection. Up to the time of writing the non-splitters are Mrs. Eric Hambro', white, a lovely flower; Miss Audrey Campbell, yellow; Carolus Duran and Sigurd, respectively buff and apricot; Countess of Paris and Lady Nina Balfour, blush; Hayes' Scarlet and Uriah Pike, crimson. If the materials are to hand, soil for layering can be mixed as soon as the plants show signs of going out of flower, and leaf soil and spent Mushroom manure, the latter thoroughly broken to pieces, with a good dash of sand, will be found a suitable compost. The addition of the manure is especially useful in dry seasons, because if it once gets a good soaking the moisture is well retained.

SWEET PEAS.—Aphis proved an early and persistent enemy this year to the Sweet Peas, and on the open border it was difficult to keep it under. Fortunately, my large batch was sown in close proximity to a water tap, and by screwing on a bit of hose and giving heavy washings on successive nights the enemy was checked and the plants went away well, a tendency to knock them out from between the sticks with the force of the water being obviated by running two or three lines of string on either side the rows. The length and stoutness of flower-stem in the newer varieties are in their way as great improvements as the advance in variety of colour, size of individual flowers and the increase in numbers, all characteristics combined enhancing their value from a cut-flower standpoint; indeed, by the aid of annuals alone, with plenty of Gypsophila, one can furnish at this season a really beautiful display, among the best, in addition to the Sweet Peas, being the deep blue Cornflower, white and yellow Sultan, Coreopsis coronata, Linum grandiflorum and Salpiglossis. A mass of a dark-flowered form of the latter is just coming out in association with a dwarf white Antirrhinum, and the effect is very pleasing. Calendulas Orange King and Sulphur Crown are just beginning to show at their

best. I mention them because in a season like the present they are valuable on light, rather poor soils. If beds devoted to them are mulched at planting time and attention is given to the prompt removal of decaying flowers they will last in bloom a long time. Another poor border plant somewhat similar in shade, but of dwarfer habit, is Gazania splendens. The mention of annuals reminds me to note the result of careful observation made this year as to the relative merits of transplanted stuff and that remaining where sown. They were sown the last week in March in a cold frame in rows 9 inches apart; the plants were at first carefully thinned to 3 inches, and as required for beds in the flower garden every second and third plant were removed, leaving those in the seed-bed 9 inches apart each way. The transplanting was carefully performed, with the result that the plants shifted came into flower, as a rule, earlier than those that remained; the latter are a trifle larger, but there is not much difference. The retention of a certain number in the seed-bed is advisable, as plenty of cuttings can be obtained here without despoiling the flower beds.

SEEDLING PERENNIALS.—The work of pricking out seedlings of hardy perennials was finished early in the week, and the dull showery time that has followed has been just the weather for them; a good soaking of the seed-boxes and also overnight of as much ground as was likely to be filled the following day prevented flagging, and they will come away quickly. They will be shaded with tiffany for a time if we get a succession of sunny days. If there is a chance of slugs being in the soil it will be advisable to look round at night, especially in the case of Delphiniums, Aquilegias or anything to which the enemy is especially partial. If a little cocco-fibre is at hand, this may be worked in between the rows and about the plants. I was rather late in sowing the Polyantus, leaving it in order to be able to put in some of this year's seed. This was secured and came up very quickly, so I am not far behind. These seedlings want lifting carefully to preserve the roots intact, and if a cool border can be found for pricking off, so much the better.

Claremont.

E. BURRELL.

Sweet Sultans.—These are most valuable flowers for cutting, especially during hot, dry seasons. They are becoming very popular with market growers of cut flowers, for, having long foot-stalks, they can be tied in bunches, and keep well in water even in the hottest weather. White, yellow, and purple are the three distinct colours. Probably the white and yellow find the greatest number of admirers, for white flowers are always in request, and yellow, especially a bright golden yellow, is very much in evidence for indoor decoration. I find that they succeed best if sown where they are to flower, for they do not transplant so well as many plants. If sown thinly in drills and thinned out to about 6 inches apart, they make splendid plants and continue to flower from July until October. Where they are grown solely for cutting it is advisable to go over the beds nearly every day and cut all fully expanded blooms. The white and purple varieties are the tallest, but the yellow makes up in quantity of flower for height of foliage. They are very effective mixed border plants, where they look best, if sown in good large clumps of distinct colours, as the foliage is of a light pleasing shade of green and decidedly ornamental. The average height of the white and purple varieties is 3 feet, and of the yellow variety 2 feet.—J. G., Gosport.

Gentiana verna.—I notice Mr. Wolley-Dod's interesting notes on this beautiful plant. I have tried it over and over again, but cannot succeed. There is one point about it which your able contributor does not notice, and that is its love for a calcareous soil. I am told in the Dolomite region it is found in abundance on the limestone formation, but not on the granite. It is abundant in the west of Ireland, and in the county of Clare I

am told it grows from a few feet above the sea-level up to 1000 feet. On that coast, too, there are always an abundance of moisture and very little frost and snow. People speak of its being covered on the Alps with its warm mantle of snow during the winter, but there is nothing of that kind in the localities which I have mentioned, and it adapts itself to these very varying circumstances. Why is it then that we cannot succeed better with it? There is also something evidently very capricious about *Gentiana acaulis* (*Gentianella*). I know, for instance, two gardens in which it flourishes abundantly. In one it occupies the edge of the border directly facing the sun and in a light ordinary garden soil. I know of another where it has been used for a number of years to form the edging of flower beds instead of Box; the edging is about a foot wide, and even when not in flower its compact and pleasing foliage makes a pretty object, and in the blooming season it is covered with a profusion of flowers. The soil in this garden is a stiff loam and the garden itself somewhat damp; in fact, no two gardens could be more opposite in their character than these, and yet it succeeds well in both, while in others it is almost impossible to get it to do well. In my own small garden I have no difficulty with it, and find it advisable to separate the clumps every two or three years.—H. H. D.

NOTES ON HARDY FLOWERS.

Showy blue flowers.—There is a want of these for the period from, say, the Crocus season and the Campanula season. What I mean by showy blue flowers is something in the way, say, of *Gentianella* or the blue *Aubrietias*, as against *Vineas*, which, though free flowering, do not show up owing to the flowers nestling in the foliage. I may mention as reliable, *Violas* in variety, *Phyteumas*, *Polemoniums*, *Veronica prostrata*, *V. incana*, *Eryngium Oliverianum*, *Gentianella*, *Linums*, *Lithospermum prostratum*, *L. purpureo-ceruleum*, *Lupins*, *Orobus vernus*, *Omphalodes verna*, *Achillea Napellus*, *Hepaticas*, *Anemone apennina*, *A. blanda*, *Camassias*, *Aubrietias*, the earlier *Larkspurs*, &c. These and similar things of easy culture may be used in duplicate according to the periods or according to weakness of numbers or variety, and in all cases where blue is intended to show out strongly, masses should be the rule.

Hippeastrum brachyandrum.—The flowers of this are striking, not so much for their size as for their colour and form. It is, however, the interest one must feel in a bulbous plant of this order when one is told that it will stand out-of-door culture in this country with but the slightest protection in the way of a few leaves, and no doubt such plants as will do in the open safely are better for being there as compared with pot culture, however well done, to say nothing of the intermittent attention bestowed on pot plants. At Reading, I hear this beautiful *Amaryllid* stands out; the flowers of sheeny silvery-purple with black-purple base outside, 3 inches to 4 inches long.

Campanula Raineri.—This is a truly grand sight just now. Surely in view of the identity of this plant being so much discussed not long ago, it cannot now, as it used to be, be needful to add that the true *Raineri* is meant, though I see still that the name "false *Raineri*" is sometimes used by way of compromise. As a flower it is bright and refined beyond description. The plant is small in all its parts excepting the flowers, and these can scarcely be covered by a two-shilling piece. Perhaps something has favoured it this season, for though I have grown it many years I never saw it so fine before either in pots or on stonework.

Heuchera sanguinea grandiflora.—“Flower-spikes 3 feet high and thicker than an ordinary penholder: flowers large, velvety and crimson-scarlet.” Such are the words I scribbled as I stood over the specimen plant in the grounds of Mr. T. Walton Merrall, whose residence is a long

way up the northern slope of the valley of Aire-dale near its convergence with Wharfedale, and not far from the highest ground or moorland in the vicinity. I mention these conditions because I feel sure the thinner and purer air has something to do with the manner in which many choice hardy flowers grow with my friend. This plant was fully exposed to sunshine, and besides was growing on a rocky bank quite 4 feet above the ordinary surface. The stems were so strong as to need no supports. We have often seen questions asked as to what should be done to make the *Heuchera sanguinea* flower better. I have come to the conclusion that it is better for deep planting, and given that it does not matter whether it is exposed or slightly shaded. The rootstocks, which are half stem-like and half rhizomatose, are, I believe, more properly in place when under the surface. Of course I do not say if these are above the surface that the plants will not flower, because I know better. Still, I think if in the same garden the rootstocks were kept well down the results would be better. I am speaking as a general rule, and, given annual or biennial replanting, by setting the roots well down, a more free-flowering habit will be developed.

Woodville, Kirkstall.

J. WOOD.

BORDER CARNATIONS AT CHELSEA.

IN Messrs. James Veitch and Sons' nursery (Ltd.), King's Road, Chelsea, there is a fine collection, embracing the best of both new and old kinds. The plants are arranged in long, narrow beds on either side of the main walk between King's Road and Brompton Road, and despite the many drawbacks of the situation—for Chelsea is by no means an ideal spot wherein to grow many flowers—the plants and, indeed, the blooms are as a whole excellent. It is in truth the border Carnation grown entirely without protection, and may be taken as an instance of its general worth and utility as a town plant. We may see here what skill may and, indeed, can accomplish with good soil, and, what is also of equal importance, good and hardily grown plants. Any, in short, that are the reverse soon go to the wall amid surroundings such as here obtain. One thing, therefore, may be taken for granted, and it is this, that the Carnation may be grown to well-nigh perfection even in a town garden, and that is sufficient variety to satisfy all lovers of the flower. Selfs of all shades, fancies, and yellow grounds are in considerable numbers and variety, while the *Picotée* is also grown, but in smaller proportion. In the open this season thrips have been a plague in many districts, yet here the flowers bore no traces of having suffered from this cause. Frequent syringing and ample watering with a light mulch on the beds of cocoa-nut fibre or the like assist in great measure to keep such things in check. No disbudding takes place; this is why the bottom laterals are teeming with buds of excellent size, that will give flowers in plenty when the main crop is past. It is, in short, the way the Carnation should be grown for the garden, and seen in this way is as instructive as it is pleasing.

VARIETIES.

The two first beds are occupied by well-known old kinds, still valuable and worth growing. These are Mrs. Frank Watts, pure white, and Joe Willet, scarlet, both very dwarf and free, of about equal height, and flowering together, are suited for association one with the other in any bedding arrangement. To another well-known kind, Alice Ayres, may almost be accorded the honour of providing the greatest mass of flowers of any kind, the blossoms appearing literally by hundreds on the bed devoted to it. In point of size, however, these have to give place to more recent sorts, such as George Macquay, the finest white we have seen. Not only is this fine kind possessed of size, but the form is excellent and the flowers full, while it figures among the freest bloomers and produces its flowers on stiff erect stems, material for layering also being abundant. It is a most

conspicuous kind in this collection. Another large white is Edith Leadenham, also a new kind. This lacks some of the fine form and finish of the previous kind, and is rather too full of petals towards the centre. It is such whites as these that place such a poor kind as Mrs. Eric Hambro' entirely in the shade, an opinion expressed with a full knowledge and appreciation of the exquisite whiteness of Mrs. Eric Hambro', which probably renders it unique. In the garden, however, and, indeed, in decoration also for that matter, we want Carnations that can hold the flowers up. Mrs. Eric Hambro' cannot do this; the stalk is so weak that every flower droops, and its effect, therefore, in the garden would be *nil*. Another very fine white is Princess Charles of Denmark, which is in every way excellent. Of scarlets there are also some good flowers, Mrs. MacRae, an improved Hayes' Scarlet, being very noticeable among them; Sweet Brier, Edward Marshall, Jim Smythe, King Arthur and Miss R. C. Barclay, light rose-scarlet, being among the best of this shade. In form, colour and petal Lady Hindlip is worthy of mention, but is not full enough compared with other good sorts. Of the crimson or light crimson shades Sir John Falstaff is among the latter and one of the largest ever raised, while Sir George Faudell Phillips as a rich deep crimson will take some beating, the flowers being not only large, but very full, strongly scented and standing the weather well. Mephisto, a smaller flower, is perfection from a garden point of view, being wonderfully free and abundant in its flowering and slightly later than others of its shade. Another shade of colour, the blush kinds, is represented by some excellent things, Her Grace, Seagull and Waterwitch being all good. For the self yellow class, always a favourite set, such kinds as Pandelli Ralli, Miss Audrey Campbell, and Hon. Harry Escombe will ever satisfy the taste in this direction, the last-named being a glorified Germania. Of apricot or allied shades the best are Mrs. Colby Sharpin, Winifred and Cinnamon, while Miss Maud Sullivan, Exile, Rose Celestial are among the best in the rose or rose-scarlet class. Bendigo is quite unique and a remarkable shade, which is very striking in a mass.

These are but a few of the best selfs in their respective colours, while the yellow grounds are as yet not touched. To-day, however, these not only form a most beautiful and useful class, but they are possessed of splendid vigorous constitutions, such as could not be found in the old time flowers of this section. This to the grower is of course a great gain, and in securing this in the present day forms of the flower, the flower itself has in no wise been neglected, but the habit and general vigour have been greatly improved. So much so is this the case, that many of the largest flowers are possessed of strong constitutions quite as vigorous as many selfs. This is most gratifying all round. Some of the gems of this set are Stanley Wrightson, Wanderer, Miss Alice Mills, Eldorado, a magnificent flower; Golden Eagle, Voltaire, very fine; Nerves, May Queen, and Mr. Nigel, every one of which has obtained a certificate of merit by reason of their excellence; the last named, Mr. Nigel, is a remarkable flower with a very heavy crimson edge. Enough has now been said to give some idea of the general worth and value of these beautiful flowers as seen in a London nursery garden. Nor is it merely a bed or two, but several dozen beds, the size of which may be gathered from the fact that it is expected to take up something like a thousand layers from each; layers, too, if we may anticipate the balls of roots at potting time, will be of the finest possible description. Close by is a large house devoted to the pot culture of the same things, and this a veritable blaze of colour and variety from which whole sheaves of blossom could be taken if required.

E. J.

Lilium chalcedonicum.—In any selection of good garden Lilies this species must be included, for it succeeds better in the open border than

many other kinds; indeed, fine established masses may be occasionally met with in old-fashioned cottage gardens. It also possesses many distinctive features, for the clear unspotted red of the flower is totally unlike that of any other Lily, while the petals are of a thick wax-like nature, and in this respect second only to the Japanese *Lilium Hansoni*. About the end of July is usually the flowering season of *L. chalcedonicum*, whose blossoms are less heavily scented than those of some others of the Martagon group to which it belongs, but even this is too pronounced for a confined place. Though *L. chalcedonicum* does not flower till a great many Lilies are over, it is one of the earliest to appear above ground in the spring. The first after *L. candidum* is *L. testaceum*, with the Japanese *L. Hansoni*, *L. chalcedonicum* following closely on its heels. The scarlet Martagon, which is the popular name of *L. chalcedonicum*, does not produce many roots, but they are all stout and of a deep descending nature. The flowers of *L. chalcedonicum* are not all of equal brilliancy, some individuals being more richly coloured than others.—H. P.

Carnation Marguerite.—I usually grow a good number of this useful and beautiful free-flowering Carnation both for lifting and potting up in the autumn for greenhouse decoration and for cutting. They always do well, last year being no exception to the rule. In a general way I have had the plants pulled up and thrown away after they have done flowering—that is, those left in the borders outdoors—but last season they looked so strong and healthy that I resolved to allow them to remain to see whether they would give a second crop of bloom. This, I am pleased to say, they are now doing, and the yield is far beyond that furnished by the plants last autumn, while in size and brilliancy of colour the flowers are equal. The plants will literally be one mass of bloom in a few days, and although the old Clove and other border Carnations are now coming into flower, the sweetly perfumed blooms of the Marguerite Carnations will be most welcome for cutting. There may be nothing new or novel in the experiment, but it is one I have never tried before. Now that it has been found to answer so well, the plants of this Carnation will in future be allowed to remain in the borders the second year instead of being consigned to the rubbish heap, as has been done heretofore. By allowing the plants to remain to bloom the second time, and by sowing seed at the beginning of the year in addition to the usual time of sowing, viz., March and April, there would be no difficulty in having Marguerite Carnations in bloom outdoors from June until very late in the autumn.—A. W.

Erigeron mucronatus.—Referring to the note of "F. W. B." on page 92 of THE GARDEN, I should say that *Erigeron mucronatus* (De C.), the Mexican Daisy, a dwarf sub-shrubby hardy perennial, with pink and white flowers, like those of a lawn Daisy, is a far commoner plant in English gardens than *Vittadenia triloba* (De C.), an Australian plant, now considered identical with *V. australis* (Richard), a New Zealand plant. The three will be found described accurately in De Candolle's "Prodiomus," vol. v., pp. 280, 281 and 285. The character which gives its specific name to the *Erigeron*—a sharp callous brown spike at the tip of each leaf—is more obvious when a lens is used than it is to the naked eye. The name-giving specific character of the *Vittadenia* is the splitting of the end of each leaf into three lobes, a character absent from the *Erigeron*. I may add that *E. mucronatus* was for twenty years at least after its introduction as a garden plant known in the trade as *Vittadenia triloba*—a plant which is tender in Edge Gardens, although hardy at Warley, in Essex. The Mexican Daisy, however, is so hardy as to survive hard winters and to become a troublesome weed on the rockeries here.—C. WOLLEY-DOD, *Edge Hall, Malpas.*

P. S.—De Candolle wrongly makes *Erigeron* of the neuter gender, but it is a good classical Greek word, and is certainly masculine.

THE WATER LILIES OF EGYPT.

WITH the kind permission of Mr. C. Schoeller, of Alexandria, I send you, for THE GARDEN, a photograph, taken by himself, of the blue star Water Lily (*Nymphaea caerulea* of Savigny and *N. stellata* of Willdenow), gathered a few weeks ago in one of its native haunts, the village of Kaf-Dawar, about eighteen miles from Alexandria on the main line of railway to Cairo. I only wish this excellent photograph could convey to you the exquisite shades of blue and green in the petals, stalks, and veined sepals of the beautiful "brides of the Nile" ("arays en Nil"), as the Arabs call the flowers of these famous Lilies. They are very fragrant in the open air, but in a closed room, or held too close to the face, are apt to remind one of that pest of our childhood—medicinal rhubarb. The leaves, which unfortunately are not represented in the photo, are large and heart-shaped, and, as a rule, have distant teeth on their edges, though sometimes they

undoubtedly first place as regards ritual importance. Entire blossoms of this species were found by Professor Schweinfurth in 1881 with their long stalks uninjured among the outer bandages of the mummy of Rameses II, now in the Gizeh Museum, and they played a prominent part among the plant remains found in 1881 among the great tomb discoveries at Dârel Bâhâri. The paintings of the blue Lotus on the temple walls of the foregoing dynasties are endless. The petals of the white Lotus were also found in the flower-wreaths with which the breast of the mummy of Rameses II. was adorned, but Dr. Schweinfurth is of opinion that it played a much less important part than the blue Lotus in the decoration of the dead, even down to Ptolemaic times. As the flowers of the *Nelumbium speciosum* (L.) (or Sacred Bean of India, China, and Japan) have never been found in pre-Ptolemaic tombs or coffins, and are not depicted on them, whilst Herodotus is the first who men-

species planted some couple of years ago. From seed saved last autumn the plants are about 9 inches high, but will not flower this year.

Coreopsis Golden Sunset. Under this name I have noted a finely coloured, large form of the useful *Coreopsis grandiflora*, one of the very best of plants for keeping up a bright display over a long season, especially in hot, dry summers. The form in question has larger flowers than the type, the colour a beautiful golden yellow. No gardener should be without this fine old plant, which is easily raised from seed; indeed, self sown plants come up by the thousand even in a heavy, cold soil. If not strictly perennial, it lasts for several years, when the old plants should be destroyed and young seedlings substituted. II.

TRIAL OF TUFTED PANSIES AT CHISWICK.

THE trial of Tufted Pansies in the gardens of the Royal Horticultural Society at Chiswick shows a marked advance over that of last year. Borders with a northern and an eastern aspect were selected for the purpose, and here the plants seem to have made considerable progress, many of them having attained large proportions and flowering freely. There were indications here and there of failure with different sorts, and this doubtless pointed to the weak constitution of such varieties.

From various raisers and trade specialists some 203 varieties were sent for trial, and six plants of each were planted out in the borders during the last week of March. From a carefully compiled record it was ascertained that certain varieties commenced to blossom about May 9, and these were succeeded by others in the course of the next week to ten days. There had been a continuous display ever since. The borders had been liberally manured and in the early summer mulched with cocoa nut fibre refuse. The plants had also been relieved of spent blossoms, this assisting very materially to keep them in a healthy condition. On the occasion of the first visit of the floral committee fifteen varieties were credited with three crosses, this being equivalent to highly commended, and it will be interesting to note the names and descriptions of these. They are as follows:—

WRAGMENT.—A miniature flower,

rather larger than the recognised size, with neat upper petals, faintly flushed with blue, lower petals white. It is a dwarf, compact variety.

DIANA.—A free-flowering and compact variety, upper petals lavender-blue, lower petals white.

JACKNAPES.—In this the upper petals are brownish-crimson, lower petals rich yellow. The only thing that can be said in its favour is that it is free-flowering and very distinct from anything else.

J. B. RIDING.—This is the well-known deep mauve sport from William Niel, and valued because of its distinct yet pleasing colour in the flower garden. The habit is very good.

SIR ROBERT FULLER.—A large pale mauve-blue flower with distinct rays and yellow eye, very much resembling a variety known as Magnificent, and possibly synonymous with that sort. The habit is tufted and compact, and the plant is also free-flowering.

COUNTESS OF HOPETOUN.—Although this variety has been introduced some years now it is still valuable. The flowers are large, rayless, and cream-white in colour. It is a free-flowering sort, though the blossoms lack the substance of those of some of the newer introductions.

MRS. H. BELLEAMY.—This is one of the prettiest of the fancy type of flower. The upper petals are pale lavender, under petals rich purple with a velvety surface. Of the type it is one of the most reliable, but more compact and tufted habit of growth is desirable.

BELTON.—The merits of this old sort were recognised probably because of its consistency. This is one of the earliest to flower, and is also seen in fine

The Blue Star Water Lily (*Nymphaea stellata*). From a photograph sent by Admiral Blomfield, Alexandria.

are quite entire. The whole plant is called by the Arabs "bishnin," and the tuberous roots, which are eaten like potatoes, "biyarâ." There are varieties of this plant in India with white, rose-coloured, or purple flowers, but in Egypt they are always blue. The only other wild Water Lily in Egypt is *Nymphaea Lotus*, L. (the Nuphar of the Arabs), which here has always white flowers, though in India there are coloured varieties, as with the *N. stellata*. The flowers of the *N. Lotus* are also called "arays en Nil" sometimes by the Arabs, and are equally common with the blue ones in wet ditches in the delta in the summer; the leaves are somewhat like those of the blue Lily, but are always serrated; the petals are obtuse, and less narrow than those of the *N. stellata*. The English white and yellow Water Lilies (*Nymphaea alba*, L., and *Nuphar luteum*, L.), though frequent in Palestine, are not found in Egypt.

As regards the antiquity of the Egyptian Water Lilies, the blue one had in early days

tions this plant in Egypt, Dr. Schweinfurth considers that it must have been introduced by the Persians and brought into prominent culture during the Græco-Roman period. During the last 1200 years of Arabo-Turkish domination both the *Nelumbium* and the Papyrus have disappeared from general cultivation in Egypt, and are only to be found in a few gardens here and there.

I wish you were here at this season to see some of our handsome trees in flower: *Poinciana regia*, *Solanum macranthum*, *Jacaranda mimosifolia*, *Tecoma stans*, gorgeous with scarlet, violet and white, blue, and chrome-yellow flowers, with their beautiful foliage.

R. W. BLOMFIELD.

Alexandria.

Alstroemerias.—These have been quite the finest flowers of the week (July 25), their rich and telling colours and the great freedom with which they are produced being strong points in their favour. Most of the plants are seedlings from *A. aurea*, *A. chilensis*, and a few other

condition late in the season. It is a most profuse bloomer, and its neat, compact style of growth, although somewhat slender, is a recommendation. The blossoms are of a deep golden yellow colour with dark rays running from the centre.

MARCHIONESS.—In this variety we have one of the very best. The plants are literally covered with pure white blossoms of the most chaste description, and as there was some mistake when this variety was first put into commerce, it is just possible some growers may have it under the name of *Niphotos*. The habit is very compact, though less tufted than some others.

MRS. C. F. GORDON.—A large handsome flower very much resembling the old Countess of Kintore, but better than that variety, especially in its habit, which is rather dwarf. This sort should supersede the last-mentioned variety if a plant less straggling in its growth is desired. Colour dark purple centre, shading to pale lavender at outer edges.

IONA.—Another of the fancy type of flower. Colour blue-black with a white blotch at the edge of each petal, upper petals lavender. It is very liable to sport. The habit, too, leaves much to be desired.

DUCHESS OF FIFE.—Quite a distinct type of plant and flower. The habit is very tufted, and plants soon attain a large size. The blossoms, which are developed on long, stout foot-stalks, are of a light primrose, distinctly edged with blue. This is a free-flowering sort.

HAMISH.—This is a bright purple-crimson flower, and a very useful colour in the border. The growth is rather strong.

PRINCESS LOUISE bears freely charming rayless canary-yellow blossoms on somewhat short flower-stalks. The habit is very dwarf and compact. The constitution, too, is excellent.

BLUE GOWN.—This, like the last-mentioned, is typical of what a Tufted Pansy should be. It is one of the most profuse bloomers, and the habit is wonderfully dwarf and compact, the constitution, too, being all that one could wish for. The colour may be described as pale mauve-blue, and the blossoms are rayless with a yellow eye.

In addition to the foregoing there were many other very fine sorts in flower, but which, perhaps, at the time of the visit of the floral committee were not at their best. Some of the most conspicuous and deserving of special mention were *White Duchess*, a beautiful white sport from *Duchess of Fife*, but with a pretty blue edging. *Goldfinch* is another member of the same family, colour yellow, edged bluish purple. *Neptune*, a fancy flower, has a rich purple centre, passing to white at the edges. *Pencaitland*, an excellent free-flowering pure white sort, has a splendid dwarf habit and with neat pencillings. *Ardwell Gem* is still one of the best, its fine sulphur-coloured blossoms very effective on the splendid dwarf style of growth. *Cordelia*, highly thought of when first introduced, with its creamy white blossoms, is still one of the best. In *Bridegroom* the flowers are of medium size, bluish-lavender in colour. The growth, too, is very dwarf. *Rosea pallida* was not so good here as is seen in most gardens, yet it was in sufficiently good form to prove its value as a pale rose bedding sort. *William Niel* was represented by free-flowering plants of a pretty shade of pale rose. *Mary Gilbert*, a first-rate golden yellow rayed flower, has a nice spreading habit of growth. *William Haig*, with its brilliant indigo-blue flowers, is superior to *Archie Grant* in point of colour. *Nellie* is one of the finest mauve-white sorts, having large rayless flowers on stout foot-stalks of good length and possesses a fine habit. *Unique* is a beautiful rich rayless yellow, a seedling from *A. J. Rowberry*. *Trent Park Yellow* is another pretty yellow rayless sort, with an orange blotch in the centre; it is also free flowering and of compact habit. There were a few good miniature sorts, including the original of the type, *Violetta*, with its fragrant flowers of pure white, flushed yellow on the lower petals and possessing a perfect habit; *Bridal Wreath*, a pure white self; *Gnome*, cream, flushed golden yellow, very dwarf; *Marginata*, white, with the faintest blue border; *Ophir*, neat, small yellow flowers, neatly edged white; *Gold Crest*, rich golden yellow, very pretty and distinct; *Lyric*, a pale bluish-lilac,

tinted lavender, very pleasing and profuse, and *Mrs. George Finlay*, cream-white, shading to yellow and very sweet scented.

D. B. CRANE.

SWEET PEA TRIALS AT READING.

QUITE recently we had an opportunity of inspecting the trials of Sweet Peas in the seed grounds of Messrs. Sutton and Sons, Reading. To render all such trials not only comparative, but very thorough and complete, every conceivable care is taken, even in the minutest details that in all probability would escape notice in those instances where there is an undoubted lack of system and thoroughness. The fullest records of all these trials are carefully preserved, so that in years to come it may be as easy as it is to-day to answer any question as to the origin of any variety, or any special or particular strain of this or that flower. So what we found to be the case among the Sweet Peas is merely part of the every-day perfect routine that here prevails with some crop or other, and with special experience to govern and assist in each and every case, the information vouchsafed is a result of the most reliable character. With the extensive trials of the Peas in question, the whole subject becomes something more than a trial; it is, indeed, a very severe test, from which only those kinds bearing promise of the highest ideals emerge with anything approaching a full measure of good points. As with many another group of florists' flowers, the highest standard of excellence to-day will undoubtedly be surpassed a decade hence, just as those of to-day have so completely eclipsed those of a past decade. The incessant onward march of progress in these flowers is, perhaps, the most interesting phase of the subject, especially when, as here, the old and the new—the former frequently dating many years back—are arranged side by side in their respective shades of colour, that their merits or otherwise are determinable at a glance. That this is possible may be gathered, perhaps, from one solitary, though important item. Not only is planting, preparing the soil, and such things carried out in the most uniform way possible, but each row throughout contained at the moment of planting precisely the same number of seeds. Therefore it is possible to decide at a glance when superior or more vigorous haulm, a denser growth and more abundant flowering appear. Many may think, perhaps, that the Messrs. Sutton have an ideal spot for growing these Peas; whereas, indeed, it is just the opposite, the soil being light, very stony, and shallow—the very soil for devouring manure wholesale. Yet in such a soil everything is still comparative so far as seed trials go. No one need fear the result if but a very ordinary soil exists wherein to grow these popular, fragrant and pretty flowers. In such a soil as that just mentioned these Sweet Peas in a season like the present are not long-lived, and particularly in a test case like that now being conducted at Reading. Where the whole crop of flowers, pods and all, remain upon the plants, early distress is more likely to ensue than is the case where the flowers are gathered as soon as opened.

The whole of this extensive trial, comprising something like 185 varieties, occupies 231 rows, each about 35 feet in length and at about 3½ feet apart, covers a very considerable area, and embraces one of the most complete assortments ever brought together.

The dwarf bedding *Cupid* is, of course, here in its several shades of pure white, blush, and pink, which is the order of arranging the whole of the kinds here. That is to say, whites of all kinds and from all sources constitute so many rows, culminating in the giant whites. The whites are followed by the blushes of all sorts, and terminate also with the giant strain of this colour. Then follow the pink, red, and other shades in precisely the same order, and so on throughout the whole of the trial. The fairness and completeness of the trial are here again exemplified, the whole of the trials being planted under number only,

arranged at headquarters and sent to the grounds for planting, this being begun and ended in a few hours. It is in this way, indeed, that the trials of these things, albeit an expensive item in itself, is rendered so thoroughly reliable. While many of the trials are undoubtedly severe, as well as singularly trustworthy in the smallest details, no attempt is made by extraordinary methods of culture to render the cultural side of the question impossible of improvement. The variety *Cupid* has already been noted, though perhaps it may be of interest to note the reason of its dwarfness, or at least one reason. This dwarfness is due partly to the loss of or blindness, perhaps, of the leading point, combined with the prompt production of lateral growth, and therefore flower at only a few inches high. The dwarfness and the abundant flowering of the plant have their uses, though these are practically restricted to pot culture and to bedding. Of the rest we can only say what is here amply demonstrated in the most convincing manner, that the strains of these Sweet Peas in their varying shades, to which the Messrs. Sutton have given the name of "giant," are giants pure and simple. Not so much in excess of vigour over the older sorts as in the size and the number of blossoms to each spray, four flowers, even in this exceedingly dry and trying season, being quite common, while in older types, such as the well-known *Invincible* for instance, only two occur. The difference was so marked, so unmistakable, at certain intervals, that it provoked the natural inquiry as to whether each row contained the same amount of seed, with the above stated result. And not only in size do these "giants" excel, but also in form, the standard in the best forms partaking somewhat of the obovate outline. As to form alone combined with substance of petal, great attention is paid by a very enthusiastic and trusted employé. The well-known white *Emily Henderson* that created something of a furore but a year or two since is now completely eclipsed by *Sutton's Giant White*, which is not only purer in every way and much larger, but devoid of the great central incurving notch at the highest point of the standard, a very great defect when seen in company with the *Giant White*, whose rounded standard is so permanently erect. This item alone has a marked effect when viewing the whole row of each kind, and in the giant strain all that is possible to be seen of the colour is seen and to advantage, a fact equally as important in decoration as in the garden. Another instance may be cited in the pink shades, viz., *Lady Penzance*, a very beautiful kind indeed, but superseded by *Giant Pink*, which is a most decided advance in the same way of colour. And what is true of the white and pink just named is equally true of almost every other hue, whether it be salmon or scarlet, cardinal or crimson, mauve or blue, and so forth, due in a very large degree to the constant watchfulness and selection that are daily going on while these things are in their prime. Of the giant race alone there would appear enough and to spare, seeing that some dozen very distinct shades exist, quite apart from intermediate shades. Of course there is a large general collection of named kinds to be seen also, and these alone are well-nigh bewildering in their apparently endless numbers; whereas the giant forms carry descriptive colour names at once simple and helpful at a glance. A few of the most striking of named kinds are *Cottage Maid*, pink standards and blush wings; *Catherine Tracey*, most delicate pink; *Venus*, salmony buff, very charming; *Grey Friar*, dusky purple-blue and white, distinct; *Emily Eckford*, deep mauve-blue, extra; *Orange Prince*, very striking shade; *Sutton's Butterfly*, pure white, with a Picotee edge of lavender-blue; *Princess of Wales*, white and blue; *Her Majesty*, rose and pale rose, one of the largest of all. Of this last there is a selection possessing identical vigour with great freedom of flowering, and having glowing rose-scarlet blooms. One very striking item in the more brilliant shades is the manner the varying shades appear on the flowers, which are as though washed on in

miniature waves, thus giving a very distinct appearance.

The above of course are but a few of the two hundred kinds grown, a large number of which are carefully preserved for test purposes. Finally, as showing the prevailing enthusiasm, we may mention that cross-fertilising is carried out on quite a large scale, which accounts for the many charming things that may be seen, but as yet not obtainable owing to stock being insufficient for the large demand. In this way numbers of beautiful things surpassing most of the named commercial kinds are utilised as pollen parents or seed bearers with the hope of still further improving an already delightful race of garden favourites. No haphazard work is countenanced and all crosses are carefully recorded.

E. J.

Nemesia strumosa.—This is remarkable for the apparently never-ending variety of colours, some of which are quite novel and very beautiful. Indeed, so great is the colour variety of this race, that beds or groups of one shade may easily be arranged in the garden and form a considerable attraction. At a glance we noted the purest white, together with lemon-sulphur, rich yellow, deep orange, rose and carmine, blue, violet, &c., sufficient indeed to satisfy all needs.

Carnation Sundridge.—This is the name given to a fine scarlet self which at a recent meeting of the Royal Horticultural Society obtained an award of merit from the floral committee, which it well deserved, the colour being rich and clear and the flowers of good size, free from calyx-splitting, so common among the best Carnations. A very curious fact, however, is that in two gardening papers the variety is described as belonging both to the tree and border sections. As a grower of Carnations, I unhesitatingly favour THE GARDEN report, which describes it as a border kind, and I imagine the true tuft of grass at the base as much as the entire absence of lateral breaks on the flowering stem will favour this view.—GROWER.

Campanula fragilis.—It is a very difficult matter to dissuade some gardeners who grow this plant that it has nothing to do with *C. isophylla* alba, which not infrequently acts as a companion plant. Yet the complaint is frequent that the above will not trail with the same freedom as the white form of *C. isophylla*. In *C. fragilis* the leaves are of a leaden hue, while the growth rarely extends to more than 8 inches or 9 inches from the plant. In the blue and white forms of *C. isophylla* the trailing masses of bloom often extend to 2½ feet in length and are covered with one sheet of flowers. In this respect it is the most beautiful of the genus, the stems much less liable to suddenly snap than in the case of *C. fragilis*.

Clematises dying.—I notice in THE GARDEN of July 23 "V." asks the cause of his Clematises dying. Among Clematis growers this vexatious occurrence is known as the Clematis disease. What it is and the cause no one yet has fully determined. Numerous experts on diseases of plants have studied the question, and the only reason they can assign is general weakness caused by excessive propagation. Enormous quantities of this plant have been propagated and hybridised, and it is not at all impossible that this has produced a weakness in the stock. The suddenness with which plants are attacked is most remarkable. I have observed cases in which plants in the morning appeared as healthy and as vigorous as one could possibly wish, and the same evening the branches have withered and turned brown, stricken, as it were, with a kind of paralysis. In some instances the whole plant is affected; in others only one branch. I may here give "V." a word of comfort as to his plants. I have found that the disease does not kill the plants outright, as in the majority of cases they break up again the following spring as vigorously as ever. That plants do recover has been proved. I have lately seen a collection which was planted last year and badly

affected, and so far they have survived and are flowering freely. That excessive propagation is the probable cause seems feasible, for I have never yet seen—and I have rare opportunity of doing so among thousands of plants this disease in such varieties as *C. Hendersoni*, *C. Flammula*, *C. montana*, *C. coriacea odorata*, and *C. paniculata*, which are propagated by layers. Some authorities have suggested as a possible remedy using the *C. Vitiella* stock for grafting in preference to *C. Vitalba*, but the use of *C. Vitiella* has not resulted in the slightest difference. Spraying with Bordeaux mixture has been tried on plants affected, but this seems of very little use.—E. S., *Woking*.

THE EREMURI.

THE eighteen or twenty species which the genus includes are natives of Asiatic Russia, Persia, Turkestan, with one exception, viz., the Hima-

Eremurus Elwesi. From a photograph sent by M. Micheli.

layan. Of this number about twelve have been introduced into gardens. The plants have a short rhizome, and are furnished with numerous stout and fleshy root-fibres. The rhizome ends in a terminal leaf shoot, out of which spring the leaves and the flower-stem. I have noticed in the greater number of species a natural tendency to sub-division in such a way that a plant that normally should bear a single flower-stem only would, after a few years, become quite a tuft of flower-stems. The Eremuri are robust plants, loving a well-drained, sunny

aspect. They begin to grow early in the spring, and after blooming when the leaves begin to fade a period of absolute rest is needed. In moist climates it is wise at that time to give them the shelter of a pane of glass to keep them from the rain. About October they start again into growth, the terminal leaf-shoot develops and is seen above the soil. Generally speaking they are impervious to the sharpest frosts, even of the hard winters that are customary in their native habitats. They yield an abundance of seed, which germinates freely, but the development of the young plant is slow, and it takes many years to acquire sufficient strength to flower.

The species *Eremurus* is divided naturally into two groups, differing widely in garden value. In one group the pedicels are upright after flowering, and the capsules, which often present a wrinkled surface, lie flat to the axis; the flowers are small and dull in colour. The varieties in this group are chiefly valuable for collections. Those which I have observed in flower were *E. altaicus*, *E. bucharicus*, *E. Kaufmanni*, *E. persicus*, *E. spectabilis*, and *E. turkestanicus*. The last is interesting for its flowers of deep brown—a rare thing in the plant kingdom.

The species of the second group are distinguished by their pedicels being horizontally displayed after flowering and their always smooth capsules. The following species of this group deserve a place in all gardens. I give them in their alphabetical order:—

EREMURUS BUNGEI (syn., *E. aurantiacus*) scarcely ever exceeds a height of from 4 feet to 5 feet, the leaves narrow and glaucous, the flowers a bright yellow and closely set on the stem. The species is robust, dividing spontaneously and giving after two or three years handsome tufts with numerous flower-stems. The blooming time is from mid-June to mid-July.

E. ELWESI.—This species is very large, the flower-stems often more than 10 feet high, bearing rose-coloured blooms. The leaf is large and of a handsome green, and remains so up to the time of flowering, which takes place about mid-May and lasts for three or four weeks.

E. HIMALAICUS.—This species is over 7 feet in height, bears pure white flowers and large leaves of a decided green, resembling those of the last-named species. It flowers from April.

E. OLGE is a rather more delicate plant than the preceding, but very pretty. The flower-stem is from 5 feet to 6 feet long, the leaf is narrow and greyish. The flowers are rose-coloured and not very closely set on the stem. It is the latest species to flower, the blooming not commencing until the first days of July.

E. ROBUSTUS is the oldest cultivated species. The stem reaches 10 feet in height, and bears midway and upwards rose-coloured flowers resembling those of *E. Elwesi*. The grey-coloured leaves are abundant and begin to fade at the time of flowering, which generally takes place about the middle of May.—M. MICHELI, in *Le Jardin*.

Gentians.—Apropos of Mr. Wolley Dod's interesting note on Gentians in THE GARDEN of July 16, I should like to say that when tramping through Bosnia and Herzegovina (Illyricum) last autumn I was greatly struck by *Gentiana*

asclepiad-a, which was growing everywhere, sometimes to the height of nearly 3 feet, but I did not notice any *G. lutea*, a plant not easily overlooked. A curious feature I noticed—I do not know if generally recognised—is that when growing in the open the leaves are practically at right angles to one another, but when growing in deep shade they lie in one plane, the whole plant curving and presenting the appearance of a Solomon's Seal. It occurred to me whether the latter form had not suggested to Pliny the description as being like an Ash leaf. I brought back seeds, but have had no luck with them, nor with the plants I bought in England, though planted in the shade in peaty soil. H. C. BAKER, *Oaklands, Almondsbury, Bristol*

STYLES IN THE ADORNMENT OF GARDENS.*

The adornment of gardens may generally be divided into three principal groups, each possessing a style of its own, and each group having its own limitations and its peculiar character. By the term "style" applied to the adornment of gardens we mean the general expression which results from an adornment created by us, whether it imitates the natural or inclines to the artificial, and so reveals our industry. So far as the ornamentation of gardens is concerned the classification may be into three groups or styles, thus:—

1. The picturesque.
2. The geometric, or mosaic.
3. The mixed, or floral.

1. PICTURESQUE OR LANDSCAPE GARDENING.

Picturesque or landscape gardening is the form of adornment which appears to be, and is, in fact, the most natural. The plants are not arranged upon any apparent plan; it includes, therefore, neither beds nor borders, although in these latter an informal distribution of the plants is admissible. And just as the word "effect" is applied in parks in order to describe them as wild, mountainous, pastoral, wooded, &c., the same word is used in this case to describe the grouping of the plants. Thus we say "an effect of perennial plants," "an effect of alpine plants," "an effect of aquatic plants," and so on, as the case may be. Picturesque adornment, therefore, includes effects of the landscape order inspired by the spontaneous distribution of plants in Nature. Naturally, small, irregular groups of plants made here and there on lawns, by the side of walks or around shrubberies are included in this category. It is to be observed also that the arrangement of the plants in all these cases aims rather at their natural distribution and harmony of form than contrasts of colour. The principal sub-divisions or sorts of picturesque adornment are:—

GROUPING OF ALPINE PLANTS AND ROCKS, reproducing certain beautiful aspects of mountains with the peculiar vegetation that pertains to rocks. These effects are more especially formed in the less cultivated parts of gardens where rocks are to be found, and are made after the idea of the mountain rocks or rocky slopes. But a group of alpine plants will not have this character if made on flat ground, and the finest effects from such a group are to be got from broken ground.

EFFECTS OF PERENNIAL AND OUTDOOR PLANTS, on the other hand, represent rather the vegetation of the plains. Groups of perennial, bulbous, annual, &c., plants give brilliant effects on level or sloping lawns, and by taking advantage of a gentle undulation in arranging the quantity of the various plants some charm-

ing effects may be obtained. Effects like these may be made in a certain spot on a lawn, as in a hollow or against a shrubbery. Such effects are the easiest to arrange, as the right plants are generally at hand. All outdoor plants arranged singly or in groups harmonise well together, and the effect of the whole is charming if the grouping is carried out with taste. Should there be rocks, it will be necessary to have near them plants that are usually seen near rocks.

EFFECTS OF AQUATIC AND BOG PLANTS.—As rock plants are the proper adornments of rocks and rocky places, so aquatic and bog plants are the right plants for the water, water-side, and moist spots in the garden. Effects of aquatic plants alone are full of charm, but it is a pity if the vegetation is confined to the water and has no place beyond the margins of the rivers or pools. By preparing the approaches in such a way that the water could reach them by overflow or infiltration, prosperous colonies of water and bog plants might be established, and would thrive in ground that was merely saturated, and thus form a link between the aquatic and land plants of the pleasure ground.

EFFECTS OF NATIVE PLANTS are almost solely composed of plants that grow in the country spontaneously, with the possible addition of some perennials. It is in some way a reproduction of local objects commonly met with in a walk across country. Such effects may be freely extended to grassy places, and thus represent pretty corners of meadows strewn with flowers in combinations capable of infinite variation. Such effects gain especially by being made in proximity to clumps of trees, on slopes, near drives, at the turnings of walks, and in outlying parts of parks and gardens. There is no need to open up vistas for them, and, in fact, their true charms lie in their being localised and their presence unsuspected.

EFFECTS OF PLANTS UNDER TREES.—These may be formed of native plants or outdoor plants from other countries, and, in certain cases and for the time being, of exotics. It would be too exclusive naturalism to admit none but native plants. All plants that grow under trees, and whose habit of growth makes them proper for companionship with trees and shrubs, may be used; but whatever the plants employed, it is essential that the flowering sorts should be grouped in the least shaded spots, whereas those whose chief beauty is their foliage, like certain sorts of Ferns, are happy in the thickets and shady depths of the wood.

EFFECTS OF SPONTANEOUSLY GROWING PLANTS differ slightly from those last referred to in the sense that instead of being a collection of many species they are confined to one, two, or three species of plants. Its simplest form is expressed by wide carpets formed of one kind of plant, presenting when in bloom a constellation of flowers to the eye. Such a carpet should be very irregular in form—that is, compact in certain places and in others more scattered, so as to admit other plants to grow in between. To a carpet made of herbaceous plants may succeed one of bulbous sorts, and *vice versa*. The plants increase, and in increasing naturalise themselves, so that after some years they seem to grow spontaneously.

EFFECTS OF TROPICAL PLANTS possess a character quite different from that of perennial plants, and they are not enhanced by their being placed in distant and out-of-the-way situations. The handsome foliage and brilliant bloom of exotic vegetation are well adapted to the accompaniment of fine buildings and the majesty of flights of steps and lofty terraces, therefore

they should be well in view of, and in the immediate neighbourhood of, the house, since their aspect is little suited to the more secluded parts of the garden. On the slope of a lawn in the front of shrubberies is their best place. Near waterfalls and rocks in the shade of great trees they are effective. The presence of Tree Ferns, of Palms, &c., imparts to the scene something of the effect of a tropical flora.

EFFECTS OF MEXICAN PLANTS.—These, which might be thought to be included in effects of tropical plants, have, in fact, a wholly different aspect, because in forming them use is made of *Cereus*, *Opuntia*, *Agave*, *Aloe*, *Euphorbia*, and in fine a whole series of succulent plants in appearance differing somewhat from those made use of in tropical effects. The effect of groups of Mexican plants is especially fine in the warm and much-broken-up parts of the garden, to which their strangeness of aspect imparts a quite peculiar character. The more uneven and rocky the site, the sharper the contrast between this species of vegetation and our own.

In the district of Paris tropical effects are possible only in summer, but in gardens of the Mediterranean region they are constantly to be admired, such as I have seen them at Cannes, Nice, Monte Carlo, Bordighera, Ospedaletti, San Remo, &c. In producing an effect of this sort it is necessary to avoid regularity as much as possible, as that would deprive it of naturalness; the majestic habit of some of these plants and the singular aspects of others are unsuited to symmetrical arrangement, at least when forming groups in broken-up places; in the adornment of terraces, as practised in the south, regular arrangement is unavoidable.

2. THE GEOMETRIC STYLE.

The geometric style, or "mosaic culture," is quite distinct from picturesque adornment. The principle and application of the two styles are dissimilar, although both aim at the decoration of gardens. In mosaic-culture symmetry is aimed at, in picturesque adornment symmetry is excluded. Mosaic-culture is the art, or at least the method, which consists in arranging plants in geometrical or fanciful designs in beds. In its very essence mosaic-culture is geometric, and thus justifies the application of this term to it. Naturally it is a style sub-divided into a variety of styles differing between themselves, not so much as regards design as in the arrangement of the plants, soil, &c. These various sorts of mosaic-culture are, it is evident, equally applicable to the permanent, winter, spring, summer, and autumn decoration of beds, borders, &c.

CARPET MOSAIC-CULTURE consists in forming designs and surfaces with plants of equal height and maintaining them in that condition, the effect of which is uniformity whether the composition is made on a flat or on a rounded surface. It is the sort most fitted for small beds and things in which simplicity should be the sole aim and wealth of details rigorously excluded. But it is different if the bed is a large one, in which case there is the danger of monotony on a large surface—a monotony accentuated by the abundance of detail and deprived of grace by uniformity in the size of the plants.

MOSAIC-CULTURE IN RELIEF differs in character from carpet mosaic-culture. It consists simply in placing in relief upon a foundation some parts and lines, or at least the principal lines, of the design. It escapes the affectation and the sometimes over-artificiality of the other; on the other hand, the lines of the design are clearly defined and their due value is accorded to them, which might otherwise be merged in the setting of the foundation. It would not be

* Translation of a paper read by M. Albert Mauné at the Congrès Horticole, 1898.

right to confine the composition to the regular outlines of beds and other formations, but rather some plants should be allowed to project into the sward, as if to continue the lines of the design. To complete the desired effect and soften the lines of the design, small groups of plants and single plants are scattered about and allowed to spring up here and there. Beds so composed have not that air of stiffness and hardness which causes so many to dislike mosaic-culture.

MIXED MOSAIC-CULTURE, or raised bedding, is a happy alliance of mosaic-culture and flower-bedding. It is simply an enlargement of the limits of mosaic-culture by the addition of plants different from those used in the formation of the design. I have seen some good examples of this in France, and it has many followers in Germany. Last summer in various centres of that country I saw many flower-beds formed in this manner. I should add that in Germany they have got beyond the strict limits of primitive mosaic-culture in applying it to large beds occupied by groups of large decorative plants; in most cases only the outlines are formed into designs picked out in the sward and set with plants of lower stature. Unfortunately, many of these compositions, though excellently conceived, are not always carried out to perfection. It will be easily observed how much this differs from carpet mosaic-culture in not having its stiffness nor its primness and conventionality, and in preserving the beauty of the plants, those forming the foundation being the only ones kept in bounds. Contrasts of form are, therefore, not excluded and have the same value as harmonious contrasts of colour.

MOSAIC-CULTURE ON BORDERS differs from the last in the sense that, given a flower-bed or a group of shrubs of a certain design, the border is to some extent detached and forms no part of it, being kept within limits of its own; whereas in the preceding we have seen that the design of the border was in close assimilation to the inner bed. This species of mosaic-culture, in which the bed is set on a border of clearly-defined limits, takes in most cases the bed formation in affecting sometimes its indentations and convolutions on the surface of the lawn; but the inner line is mostly parallel with the outer, or, if not, it is so detached from it that they cannot be regarded as parts of the same bed. Here, therefore, we have two things which to some extent are the complement of each other, but which may very well be detached and carried out separately, which is not the case in mixed mosaic-culture. Mosaic-culture in borders is, therefore, to some extent the frame to another composition, which it serves to throw into relief by forming a distinct contrast to it.

3. THE MIXED OR COMPOSITE STYLE.

The mixed or composite style, which I will call floral adornment simply, is characterised by its unicolor or multicolor combinations in beds, borders, &c. It is the style most favoured in France. The chief object of floral adornment proper, as I understand it, is to obtain contrasts, either by the happy association of fine-foliaged plants, or of flowering plants, or of both together. This style is the harmonious mingling together, or rather assembling, of the two preceding, by borrowing regularity from the one and picturesqueness from the other. It is in some sort the concordance, the mediation, the correlation of those, just as in garden architecture the composite serves as the transition between the symmetric and the landscape styles. The mixed style includes beds of

various sorts, borders, &c., of any form, the plants being disposed with more or less regularity, but not affecting any design. It is easy to perceive the transition between mosaic-culture on the one hand and picturesque adornment on the other, by the combinations of small plants arranged in unicolor lines, in which it approaches more to mosaic-culture, and the compositions in which large plants enter and which incline more to the picturesque. Beds of perennials, for example, are in their character and essence a very perceptible approach to natural grouping of varied plants, although possibly amid geometric surroundings. In a word, all regular or irregular formations, if disposed upon one or more lines, whatever the disposition of the interior, if not mosaic-culture, are included in the mixed style. Let us now consider the principal kinds of floral adornment.

UNICOLOR COMPOSITIONS.—These are characterised by the use in beds of leafing or flowering plants of the same colour, with or without the intervention of lines of other plants; generally plants of medium height are used for this purpose. This style is used chiefly in the distant parts of the garden, because masses of uniform colour gain by being seen from a distance. Or, again, if several beds are situated in a relatively limited circle and comprised in one visual radius; in that case each bed should present a different colour, and all satisfy the view by fulfilling the principles that govern the association of colours.

COMPOSITIONS IN PARALLEL UNICOLOR LINES.—This, which differs from the preceding in that the variously-coloured plants are arranged in concentric and parallel rows more or less spaced out, is now little used. It is reproached, justly perhaps, with being not particularly pleasing and slightly monotonous. However that may be, and admitting the defects, it has the advantage of an orderly arrangement of the plants and of helping symmetrical contrasts of forms and colours, and, therefore, ought not to be despised in the adornment of beds, the more so as, instead of being bound to make each line a different colour, we are free to repeat the same plants in many parallel lines so as to get broad stripes of uniform colour.

SCATTERED GROUPS OF MULTICOLOR COMPOSITIONS, as they may be called, are obtained by grouping plants of nearly the same stature and different leaf and colour of flower. The disposition is generally made regularly in symmetrical beds and borders, and irregularly in other beds. This kind of composition has certainly many attractions, especially in beds intended to be seen from near, because it allows of the grouping in a single homogeneous mass of a whole series of plants different in form and colour, fine-foliaged plants and flowering plants, but it is a mistake to use it for beds in distant parts of the garden.

PLANTING IN SCATTERED GROUPS is only a modified form of the preceding, differing from it in the arrangement of the plants in groups of several. Such a composition is preferable for distant beds, because the patches of single colour are larger and therefore more visible.

PLANTING IN IRREGULAR GROUPS.—This has considerable points of difference from the preceding. The name was suggested to me last year by seeing two beds so composed at the Municipal School of Arboriculture in Paris. There are several ways of applying it. Its chief peculiarity is in the disposition of large irregular groups of the same plants, or of different plants, and in the latter case plants of different heights can be employed. Its peculiar characteristic is precisely this, that it leaves a

wide field to the gardener in the formation of groups as regards the heights and colours of the plants, provided the general effect is agreeable to the eye. It is a form of garden adornment which deserves special attention, because offering variety and taking us away from hackneyed compositions in which only plants of like dimensions are used.

GROUPS OF ISOLATED PLANTS. In these, fine-foliaged plants are scattered and stand out from a base of other smaller plants, which are intended to show them off to advantage. Saving the last, all those methods just described must in some way be composed of plants of the same height. Beds arranged on this plan are meant to be seen from near; at a distance they produce only a relative effect owing to the great diversity of form, which remoteness blends into a mass, with none of the brightness of colour and elegance of isolated plants. It is not necessary that the isolated plants should be very high; the essential point is that they should stand out boldly from the background.

GROUPS WITH PLANTS OF LARGE GROWTH.—This is applicable to flower-beds of large extent. It consists in grouping fine-foliaged plants, allowing sufficient space for each to enable it to acquire the development which is its beauty. But as when first placed in the beds these plants are small, in order to fill up the bare spaces between, other plants will have to be inserted until the first shall have attained their normal development. This kind of planting is not to be confounded with groups made of isolated plants, in which the plants are so placed as never to touch and the vegetation of the foundation is permanent.

MIXED GROUPS.—These differ from all those hitherto described in having a special application to large flower-beds and the regular borders of shrubberies. They consist in the association of outdoor plants with greenhouse, perennial, bulbous, annual, and other plants, and constitute a permanent adornment, being at their best from April to November. If made with care they furnish flowers in all seasons, and if, indeed, they do not give such brilliant effects, they are not so ephemeral as the beds of a season. It is a kind of adornment which has nothing formal about it, and which has surprises for all times. Side by side with an open flower it gives us another with buds as yet unopened. Beds so adorned, with their air of primitive simplicity, absence of premeditation, and diversity of mass and detail, exercise an indefinable but very powerful charm.

GROUPS OF TWINING PLANTS.—These are formed especially for shrubberies and are delicious in their prettiness. The branches of these plants entwine themselves amongst the shrubs and form a mass of delightful confusion crowned with an abundance of blooms. In addition to the kinds of floral adornment above described, there are many others which are not included in one or other of them, and it will be sufficient if I mention the fact.

4. APPLICATION OF THE DIFFERENT STYLES OF GARDEN ADORNMENT.

I think it will not be useless to compare each of these styles and shortly say how it is characterised.

PICTURESQUE ADORNMENT is the truest, and therefore seems to be the most natural, the most expressive, and the most æsthetic. It is not, however, wild Nature, nor does it borrow from that more than its most seducing aspects.

MOSAIC-CULTURE is the result of much study, like a new style in architecture. It is artificial in the complete sense of the term, but for that very reason it wins the admiration of the crowd

by the sense of difficulty overcome which it inspires.

FLORAL ADORNMENT is not, and visibly is not, the result of so much painstaking as mosaic-culture, and yet a handsome bed is most frequently only the result of very careful combination; but visually it does not seem to be as conventional as mosaic-culture. Many people have for it the sense of the beautiful which they feel in the presence of landscape scenery.

As regards the application of the different kinds of adornment in gardens, it would be rash to attempt to lay down rules which could have no force than so far as they satisfied the majority of tastes—a very difficult matter. Nevertheless, the application of every one of these three styles is governed by the surroundings. All are far from producing the same effect in a garden, and the impression they make upon us differs greatly for that very reason. There are people who like their flower-beds scattered over lawns, whilst others, on the contrary, have a preference for opening up fine prospects and will not tolerate the presence of any flower-beds to break the view. For those who do not care for flower surfaces regularly set out, what is wanted is some landscape effects made along shrubberies, near drives, &c., without, however, intercepting from the view that natural level of the ground which is one of the chief beauties of a park. The different parts of a garden or a park allow of the employment in various conditions of many plants calling for peculiar treatment. Thus in coverts and woods plants may be sown which thrive in these conditions, and carpets of flowers established in the clearings, and, again, the depths of woods will be a home for Ferns. And in order to avoid the appearance of abruptness, plants which are fond of half-shaded places may be scattered about the sward in the foreground. Rough parts and corners of the garden may be used to form a scene of alpine and kindred plants. It is a mere truism to say that aquatic plants and bog plants cannot be established in places where there is no water; but where we have a river, rivulet, or lake, in which to create a landscape effect of aquatic and bog plants, nothing is prettier or more picturesque than the vegetation of the waterside. Places near the house, the foot of terraces, or lawns are the most fitting for making effects of tropical plants; but, principally, it is near rocks and narrow streams that such effects are seen in all their beauty. Whilst the higher rocks are planted with Agave, Opuntia, &c., scattered over the lower ones will be Tree Ferns, Bamboos, Palms, &c. Such an arrangement not only gives a semblance of exotic vegetation, but recalls at the same time some corners of the beautiful Mediterranean coast. The borders of shrubberies, drives, and walks are the best fitted for the formation of hardy-plant and varied-plant views. Such plants must be disposed with taste in well-defined masses sometimes, and sometimes isolated and detached.

Whilst there are certain effects of landscape plants which are especially interesting when localised, it is quite otherwise with mosaic-culture. A design in mosaic-culture ought principally to be carried out in some part of the garden close to the house, or much frequented; in which case it may, equally with any other form of adornment, fulfil an end.

In a large garden, especially if the proportions are made to correspond with the surroundings, and even if the view includes an effect of the landscape order, a formation in mosaic-culture will not be out of harmony, especially if the mixed kinds are adopted, and in relief. In a landscape garden a bed in mosaic-culture

should be set in the very approaches to the dwelling-house, or at least near to it and in the line of view. Such planting may also be made near summer-houses and garden seats, if these are not placed in retired spots, and around trees and shrubberies; but, in my opinion, it is a great mistake to dot them over lawns, to the total exclusion almost of other kinds of ornamentation, as is frequently seen. In such a case a part of the garden will lose in harmony from this conventional decoration.

In floral adornment, properly so called, there is no need whatever to observe such absolute restriction, although neither should the flower-beds be scattered about at random. In landscape gardens of average size numerous flower-beds are placed about near the dwelling-house and places that are much frequented. In villa gardens in the suburbs of large towns, to make up for the absence of exterior views, views are

Iris alata.

made in the garden itself by focussing them on the flower-beds. Great restraint should be exercised in the distribution of flowers in large parks, especially if these are of the picturesque order; it is important to observe that air of naturalness which the architect has impressed upon them, and not stultify his work by scattering here and there flower-beds which are in fact only suited to the entrances and to the approaches to the dwelling-house. It is different, however, in the case of public gardens, in which the taste is generally for profusion in flowers, especially if the gardens are small. In large parks the distribution of flowers may be more moderate. It goes without saying that geometric gardens are in all respects a fitting framework for floral adornment. I have said that it is well to subordinate ornamentation to the charac-

ter of the place. That opinion is not exaggerated. Here is an example. In the gardens about Paris it is the practice to form effects of alpine plants in the most distant part of the garden; in mountainous parts of the country, on the other hand, there is no hesitation about establishing them close to the house, and that seems to be in no way remarkable. Under the blue sky of the Mediterranean, however, fine exotic plants are grouped as much in the remoter parts as in those near to the house, and it seems the right thing to do, as the plants grow naturally.

GARDEN FLORA.

PLATE 1182.

IRIS AITCHISONI.

(WITH A COLOURED PLATE.*)

THE so-called Juno group of bulbous Irises, of which *I. persica* and *I. alata* are perhaps the best known examples, has its headquarters in the East; the species are most abundant in Asia Minor, Persia, Turkestan, and Bokhara. Towards the west the group is represented by *I. alata*, reaching to Southern Spain and Algiers. Towards the east the group reaches into Afghanistan and the Punjab, and is here represented by three very well-marked species, *I. Stocksii*, *I. Fosteriana*, and *I. Aitchisoni* (I omit the little-known *I. drepanophylla* of Baker), which put on very special characters. The leaves, instead of being fairly broad, as in *I. alata* and others, tend to become very narrow, almost linear, and the bulb, instead of being thick and fleshy, becomes narrow and thin.

I. Aitchisoni was first described by Mr. Baker in the "Journal of Botany" for 1875 (p. 108) from specimens gathered near Mount Tilla, in the Jhelum district of the Punjab, by the distinguished botanist Dr. Aitchison, whose services in the Afghan campaign, and later in the Boundary Commission, are so well known. Naturally, it was named after him. It is also said to have been gathered in Afghanistan by Griffith. The bulb is long and slender, with reddish brown tunics, and the fleshy store roots, so characteristic of the Juno section, are also slender and delicate as compared, for instance, with those of *I. persica*. In these respects *I. Aitchisoni* resembles *I. Fosteriana*. The leaves are narrow and lax, and the stem, a foot or more in height, bears one, two, or three flowers. The flower resembles that of other Juno Irises in that the inner segments of the perianth, or "standards," are small, narrow, and extended horizontally, not erect, but differs from at least the majority of them in that the outer segments, or "falls," have no wing-like lateral expansions. The fall is broadest where the blade joins the claw, but is not extended here into a definite wing. The styles, as in other Juno Irises, are large and conspicuous.

* Drawn for THE GARDEN from flowers sent by Professor Michael Foster, Cambridge. Lithographed and printed by J. L. Goffart.

The specimen figured in the plate is the typical form, purple of one shade or another being the dominant colour. The claw of the fall is marked by radiating purple veins on a creamy yellow ground; these over the blade are fused into a general ground colour of very rich deep purple, with which the full bright orange of a short raised median crest forms a pleasing contrast. The styles are of a lighter purple, and the slender horizontal standards are nearly white except at the purple tips. There is also a distinct golden yellow variety, the var. *chrysantha* (Baker), which Dr. Aitchison says is a stouter plant than the type. The plant occurs near Rawul Pindi, and on the road thence to Peshawur, the first specimens ever collected being gathered by Vicary in the first Afghan campaign, at the Murgullah Pass on this road. It is also found at Mount Tilla, in the Jhelum district, and throughout the salt range. The yellow form has been found only in the Park at Rawul Pindi, but Aitchison, in 1893, transplanted bulbs of it thence to Mount Tilla. Griffith also gathered the species, probably from the Rawul Pindi source, though Otipore, in Afghanistan (not Otipore, in India), is quoted by Boissier as Griffith's source.

I fear the plant, charming as it is, will never flourish in our English gardens. Left to itself, it starts into growth in October and November, but is wholly unfitted to withstand an ordinary English winter. Nor is there much hope of keeping it by taking it up and planting it late, for, like *I. Fosteriana*, it very much resents being moved, a feature which is probably connected with the slender character of the bulb. In general, it needs the treatment of other Juno Irises, but even more than most of them needs a summer's baking. M. FOSTER.

THE WEEK'S WORK.

HARDY FRUIT GARDEN.

PEACHES AND NECTARINES.—ROUTINE WORK.—Continue to follow out the instructions given ament those trees from which the fruits have been gathered, taking particular care that none of them are allowed to suffer from want of water. Do not allow the borders to be trodden upon directly, but, in the absence of trellises, lay down boards. If by any chance such has not been the case, look to it at once and gently break up the surface. Then, when watering is done, a more equal distribution will be secured. More water is needed around the stems and at a moderate distance from them than is the case towards the extreme parts of the border. With the late warm weather it may be possible that red spider is gaining ground; if so, give more frequent syringings. The extremities of the trees are oftentimes the first parts to be attacked. If any trees still show signs of making growth, which it is plain to see will be superfluous, remove all such by degrees if very sappy, so as not to again set up reaction. Afford a generous treatment to all late crops, especially so in the case of such as Sea Eagle and others, which oftentimes bear profusely. Still continue to give these manurial stimulants. That from the farmyard or other cess-pools will answer well; blood manure will not be too exciting where the trees are heavily laden. It pays to have provision made under glass for the latest of our Peaches and Nectarines. Oftentimes on the open walls they do not mature in the most satisfactory manner, yet it is a most indispensable crop—as at the commencement of the shooting season, for instance. When Peaches and Nectarines can be continued well into October they are a great acquisition to the dessert.

LIFTING THE TREES IN THE EARLY HOUSES.—Perhaps some may be disposed to think that this work is as yet somewhat premature. Such, how-

ever, is far from being the case. Mr. Speed, Penrhyn Castle Gardens, makes it a rule to lift his trees almost, if not quite, every season, as he finds by so doing he is more certain of good crops. Let those who are troubled by non-fertility or other failures take note of this and give the system a trial. The plan adopted is to lift the trees thus early, say by the middle of August, whilst the leaves are still upon them in a fresh condition, but not in a sappy growth. Fresh soil not being needed every year, the question of labour only is

work earlier in the case of large trees or younger ones that are all too luxuriant when under glass is an advantage that must be apparent.

POT TREES.—Where the fruits are all gathered from these, the trees, if not too large, should be stood outside in a sunny, well-exposed situation. Not only will this treatment be congenial to them, but it will afford room at the same time for those things which may need thinning out from other houses. If a plot of ground be vacant, these pot trees should be plunged upon it at about the same distance apart as when growing and fruiting under glass. Thus treated the wood will become thoroughly well ripened by potting time early in next month. When plunging these trees take the precaution to place a brick or two under the pots to ensure a clear passage for the water and around the pots a few shovelfuls of cinder ashes to keep away the worms, which will be first attracted by the moisture, and afterwards be tempted to gain an entrance into the pots. By plunging the trees they are safer also when strong winds prevail. See to it that these trees do not suffer from want of water. They will not, as a matter of course, need quite so profuse a supply, but yet a fairly good quantity. Late pot trees upon which the fruits are still green, such as late kinds, should be mulched if they are bearing good average crops of fruit. It will assist them to finish their crops and save a little watering at least. Plums in pots require the same treatment. These I find quite indispensable for supplying first-class dessert fruits during September, particularly towards the end of the month. Where Plums are a reliable quantity on walls outside this may not apply with so much force. Under glass the best dessert Plums do not crack during wet weather, whilst they are easily made safe from the attacks of wasps. Their culture also in pots is not by any means difficult.

APRICOTS.—These where protected by glass will need more watering than when on the open walls, otherwise the fruits will not be so juicy. Rich and luscious they may be, but when shrivelled they do not look quite so tempting when placed upon the table. In order to avoid any excessive watering being necessary a mulching of short litter will be an assistance, not so much a manurial mulch as one for preventing excessive evaporation. Do not in any case foster or otherwise encourage a rank growth, to which young trees are often liable; this will ultimately engender that much-to-be-dreaded disease the canker. As soon as the fruits are all gathered a good washing will do the trees good.

taken into account. Care should be taken that the borders are in good working condition for moving the soil. Let the work be done expeditiously, and if need be shade the trees for a time afterwards as well as during the process of lifting. Use the syringe also to prevent the leaves from withering and the shoots from shrivelling. That this early lifting is sound in practice everyone knows who has had charge of these fruits in pots, the potting of which is better done quite early in September when standing outside. To do the

CHERRIES.—As indoor permanent trees these are not grown so much as they might be. The time-honoured plan of taking off the top lights answers well for Cherries. It should be done as soon as the crop is all picked, when also, as in the case of Apricots, a liberal use of the syringe occasionally will clear away any insect pests. With the removal of the top lights do not, however, be betrayed into a sense of security as regards watering, but rather give a liberal supply with, in

Iris persica.

addition, a dressing of either bone-meal or an artificial manure with a good percentage of phosphates. This will provide them with the needful food for passing safely through the stoning process another season.

OVERCROWDING FRUIT HOUSES.—This matter has been alluded to before, but it will bear repetition now. It is bad alike for both the permanent occupants and the temporary ones. In the latter case a weak, spindly growth is oftentimes the result, whilst it is at the same time a means of communicating such insect pests as the mealy bug and various forms of scale, where otherwise in most instances the fruit trees would be free from them. Too many plants are frequently grown and too much is oftentimes attempted in this direction, to the detriment of all concerned. Clear out wherever possible is the advice now given.

ALPINE STRAWBERRIES.—Those plants which commenced to bear at the same time as Royal Sovereign are still giving good returns, quite equal in fact as regards size and even better as regards flavour than the earliest. Another fortnight's supply at least even with the dry weather is quite possible. By that time the plants raised last year from seed will be in good bearing condition. These in relays will then carry on the supply towards the end of October without any difficulty. So far this season the birds have given but little trouble; the later crops, however, will almost be certain to be attacked. It may possibly be the preponderance of insect pests which has attracted more of their attention. The seedling plants of this year are all now planted out from the boxes in which they had been nursed, the favoured spot being under a high wall facing east. There they will remain until a plot of ground becomes vacant in October.

NOTES.

KITCHEN GARDEN.

GENERAL WORK.—Owing to the drought it will not be an easy matter to keep crops going. Peas are soon over, and this is to be regretted, as the crop this season was a heavy one. For later crops it will be necessary to mulch and water freely to keep the baulm in a healthy condition. I notice dwarf Beans are becoming badly infested with red spider, and to check the spread of this pest I would advise watering overhead late in the day to keep the foliage moist at night. This will prevent the pest gaining headway. Winter green stuffs will need moisture to keep the root growth active, and a thorough watering is preferable to dribbles. Plants placed between rows of Potatoes should now have full exposure, as the tops may be reduced, or, at any rate, bent over to give room. A weak plant will not have time to make up lost time when the Potato crop is lifted. Celery should be flooded once or twice a week to prevent the roots drying, and late-planted Leeks will need similar treatment; indeed, much time will be taken up in supplying moisture till we get a change in the weather. Small seeds sown as advised a short time ago will make slow progress unless given ample moisture. Germination may be hastened by covering with mats till the plants show through the soil.

ASPARAGUS.—I find the growths are none too strong this season, and in light soils lost time may still be made up by liberal supplies of food and moisture. I would strongly advise feeding now rather than in the late autumn, as is often done when top growth has ceased, as now the plant will benefit greatly. Few foods are superior to liquid manure where it can be obtained, and if a system of irrigation can be followed so much the better. Beds on the flat are less influenced by drought than raised beds, and in the former position moisture can be given in larger quantities without running to waste in the alleys. It must be borne in mind that the roots are far-reaching, and the moisture given should be liberal. Soot and salt are excellent at this season if there is an ample supply of moisture after the dressing is

given. Nitrates and such food as guano and fish manure may now be given. Any of these latter are best given, say, every ten days in small quantities in preference to large doses less frequently. Recently planted or sown beds will need more frequent supplies, as the root-hold is small. The plants will also benefit by a mulch of spent manure over the surface. Failing this, it is a good plan to hoe frequently both before and after giving food or moisture.

SEAKALE.—Plants intended for early forcing may with advantage get attention, and if liquid manure can be spared, give the same liberally and as often as it can be spared. The larger plants for forcing should have the small side growths removed. One crown in most cases will suffice, and all flower-heads should be cut off. It is well to give the plants ample space to develop the top growth, as upon this will depend the size of crowns made. Much the same advice holds good as regards the supply of food as advised for Asparagus, but Seakale will take it stronger, as the fleshy roots will soon absorb the food given. Soot and salt, or any food of a saline nature, suit Seakale, and now is the best time to apply the same. Whatever is given should be of a quick-acting nature. This should be conveyed to the roots freely by irrigation or liberal supplies of water. Young plants should be thinned, if at all thick, to give the leaves space, as if at all crowded the crown growth will be weak, and even if not needed for forcing this year, supplies of salt and soot will be well repaid.

VEGETABLE MARROWS.—These are fairly plentiful, and the supply may be kept going over a much longer period if a little extra attention is paid the plants at this season. After hot dry weather Marrows are frequently badly attacked by mildew, and to prevent this I have cut back the old foliage freely, shortened long trailing growths, and obtained new ones closer home. Plants in full bearing will be benefited by copious supplies of liquid manure, and if a mulch of decayed manure can be given they will suffer less from drought, and fruit till cut down by frost. It is not a good plan to allow these plants to go just where they like; much better thin out any crowded shoots and frequently stop others. Plants in bearing should not be allowed to mature seed; indeed, the fruits should be cut before the seed forms. If seed is needed, much better let one plant carry the seed crop, as it is certain that mildew will fasten upon plants in a crowded state or bearing small and large fruits. Late plants for an autumn supply should not be allowed to bear heavy crops till there is plenty of bine, and these may be fed liberally from this date.

EARLY CELERY.—The season of late has not been all one may desire for Celery, as unless copious supplies of moisture can be given it is useless to advise earthing up. With early Celery there is a difficulty, as with the best possible culture the plants bolt or become pipy, and then are useless. To prevent this it is far better to delay moulding up and give copious supplies of moisture. I find it a good plan with dry soil to earth the plants up gradually; this allows moisture to be given freely, as if a final earthing up is given it is a difficult matter to reach the roots afterwards. Only earth up sufficient for immediate wants; far better allow plants to make their growth than retard by premature earthing. Plants in full vigour will now take liberal supplies of food. I have great faith in soot and salt, these adding greatly to flavour and keeping slugs at bay. I have seen Celery flooded with crude liquid manure, but it should be toned down, as, though less injurious given now than later in the season, if at all rank it will cause premature decay in the centre of the plants. Far better dilute the food given and then there will be less fear of injury later on.

DWARF BEANS.—I find a quarter of late sown French Beans of great value at the latter part of September, as though we may get enough frost to injure the old plants that have been some time in bearing, the younger ones on a sheltered border may be saved. Another point deserving atten-

tion is that dwarf Beans in the autumn are always welcome, as they are much liked with game. In exposed gardens I have sown this crop in turf pits or in positions where a movable frame can be placed over the plants. For the purpose named a dwarf variety, such as Syon House or Early Favourite, will be most suitable. The latter I prefer, having a stronger haulm, and, though dwarf, it is most prolific. The soil should be well enriched, and it will be advisable to sow in deep drills, these preventing moisture escaping. If the soil is dry, it will be well to soak the drills previous to sowing to assist the seed to germinate quickly, as the season of growth is now none too long. This will be preferable to soaking the seed, as the soil being warm root growth is rapid. I sow in rows 2 feet apart, and thin the plants to 6 inches in the row.

AUTUMN LETTUCE.—A liberal sowing made now will provide a late autumn supply, and, should any of the plants not turn in freely, these will be just the material for lifting and housing for December supplies. It is the large blanched Lettuce that frost injures most, and though it is now full late to expect large heads, they will be large enough for most purposes if the seed be sown now and the beds well supplied with moisture. It is too early to sow for what may be termed early spring supplies in the warmer parts of the country, as the plants would be too large. This sowing may be made towards the end of the month. What I would advise now is a quick grower. Golden Queen and Perfect Gem are noted for their quick growth, and Sutton's Intermediate, one of the newer Cos varieties, is a fine winter Lettuce. With the soil in a dry state it will be well to cover the seed-bed with mats to assist germination, and transplant as soon as large enough. For lifting into frames in the autumn I have found it advisable to sow in drills, thin out freely, and leave the plants needed for lifting. Grown thus they make a good growth by the end of October and are larger. The thinnings will provide a supply for the salad bowl during the month named if given rich soil and ample space.

HERBS.—Mint cut over early in the season will now have made a nice growth and be in condition for drying. This herb is always in request through the winter months, and to get the best flavour it should be dried slowly by spreading it out thinly on floors or shelves before tying up in bundles. Other herbs, such as Tarragon, need much the same treatment, and the Savory, both summer and winter, may now be cut. The latter is not always needed, as it keeps green, but in severe weather it is not always procurable. Rosemary is useful in a dry state, and any other sweet herbs should be cut and dried. I suspend mine in small bunches to the roof of a cool store, and here they keep grandly. If the supply of Basil be at all short a sowing made now will furnish good heads by October. This may be sown thinly in boxes or in a cold frame if the weather is hot and dry. Fennel and Borage may now be cut down to within 6 inches of the soil if seed is not needed. Garlic and Shallots are used largely for flavouring. These should be lifted and dried and stored in a cool place for later use. I find these keep best tied in small bunches, as advised for herbs, and hung up. S. M.

Crassula jasminea.—I quite agree with what "T." (p. 67) says of this useful summer-flowering plant, and wonder why it is not more often met with. Presumably the demand for this miniature Crassula is by no means brisk, for on inquiry last autumn at one of the principal London nurseries, it neither found a place in their catalogues nor among the large store of plants to be seen in almost endless variety, and when ordered from another source quite a different plant was sent. By reason of its waxy texture it is not nearly so fleeting in its blossom as many summer-flowering plants. Like many another greenhouse subject, too, a solitary specimen conveys but a poor impression of its value. If grown largely like

Cinerarias, Primulas, Carnations, and other kindred subjects its value would be considerably enhanced, and particularly if its culture were as well understood and encouraged. It certainly deserves better treatment than is accorded it at the present time, and all that is needed to bring this about is for one of the leading growers to take it in hand and place it before the gardening public in quantity, so that its intrinsic value can be ascertained.—S.

ROSE GARDEN.

ROSE CULTIVATION ON THE MEDITERRANEAN COAST.

IN the north the season of rest for the Rose bush is that which comes with the lowering of the temperature in winter. In southern regions it is during the summer that this occurs, being caused by excessive drought which puts an end to all vegetation. The period of rest, which it is so important to take into account, may be determined by causes diametrically opposed to each other, since by excess of cold or of heat the same result is brought about. With this difference, however, that on the Mediterranean shore, in spite of the excessive dryness which characterises this region and of the facility with which in many cases watering might be applied, the grower for market will take good care not to resort to watering if he wishes for a regular bloom in winter. The conditions of climate, which are so different in these two regions, although situated at a distance apart relatively inconsiderable, make all the difference as regards the time of pruning, which in the south is from the commencement of September until October or even later, depending on whether the grower has greenhouse or outdoor plants to deal with, and his object is to get an early or a late bloom. Some twenty years ago the cultivation of the Rose was more lucrative in the south than it is at present, owing to its inexpensiveness, as the only protection needed was the azure vault of the fair sky of Provence, and the pruning season lasted not nearly so long. To-day, however, when, owing to the demands of commerce, late Roses pay much better than early ones, all the energies of the grower are directed towards procuring late blooms, although, to make success certain, artificial shelter, such as canvas, mats, and glass, is required. Despite the praises lavished upon the climate of the Mediterranean shore by persons concerned rather with the poetry of language than with looking at facts from the point of view of practical horticulture, it is the fact that frosts from 1° to 3° are of such frequency, that almost yearly, at one point or another on the sea-coast, the Rose buds are regularly killed by frost.

The Rose Safrano is the most met with. Although constantly threatened with the loss of its throne by the advent of some new variety, it, nevertheless, holds the reputation which it has long enjoyed, and is still planted largely. Safrano is not given glass shelter; at most it is allowed the protection of canvas or mats in situations which are favourable to it as regards temperature. Temperature differs enormously at points distant only from each other by some hundreds of yards, according to the disposition or configuration of the hills which protect these plantations from the more or less direct influence of the sea, and particularly the hour of the day at which the sun shines upon the plantations; light shelters, moreover, being used only to protect the plants from the ill effects of morning frosts known to

all southern growers who have experienced their disastrous consequences.

At first sight it might appear that the time of pruning would have an enormous influence upon the time of bloom. For some years the most careful growers have devoted all their energies to obtaining plenty of bloom somewhere about Christmas and the new year, a period of great activity in the Rose market; and with this in view they are accustomed to prune about September 20. But there is nothing precisely settled, and, in fact, the period of pruning is only a secondary consideration. A Rose bush pruned in August will seldom start into growth before one pruned in September should the first rains not fall until October. Growers, however, who prune in August and are able to water their plants may easily get a part of the plants in bloom by the time of All Saints, a period when the market is also fairly active, especially if the frosts have been unusually early in the north.

The period when Safrano Roses are very difficult to obtain is that between the end of January and the middle of March, and yet just at this time it is most important they should be abundant in order to effect the most remunerative sales; and it is this consideration that has governed the operations of not a few growers, who, without taking any account of the means at their disposal or the situation—more or less advantageous—of their plantations, have not hesitated to prune very early or very late. This difference between the periods at which the pruning may take place with the same results—that is to say, regular production from January 15 to March 15—calls for a short explanation. Safrano Rose on the sea-coast flowers at two different times, the one commencing November or December. The cutting of the blooms, by necessitating the removal of the shoots at a certain length, fulfils the object of a green pruning and drives the sap back to the eyes of the base. This developing afresh forms new flowering shoots, which bloom, or at least form buds, and under ordinary conditions are ready to be gathered towards the middle of March or the first fortnight in April. In computing seventy-five to eighty days as the period necessary for a shoot to develop completely its bud, it would seem at first sight that, barring accidents from frost, the first gatherings made, say November 15, should cause the putting forth of new buds about January 15, and that, on the same principle, late pruning performed say in November, and in the absence of accidents from frost, the result would be the same. But this is not the case, because if a period of seventy-five to eighty days is sufficient for the complete emission of a bud, the condition is not impliedly fulfilled unless during that period the Rose bush has enjoyed by natural or artificial agency the influence of a sum total of 750° to 800° of heat. From September 15 to the end of November in the open air on the coast region this condition is always to a great extent fulfilled, but it is otherwise in the same region from November 15 to the end of January, a period in which the heat falls off several hundred degrees; so that the first gatherings coinciding with an epoch at which the fall in temperature is relatively more and more marked, the flower branches do not put forth their second blooms any earlier than those which were pruned at a later date, because, owing to that very fall of temperature, the first remained latent for several weeks.

The southern growers then make a mistake every time that, by early or late pruning, counter pruning, or removal of shoots, performed without other adjuncts than that of

matting and canvas, even in places reputed to be the warmest, they aim at regularly producing the Safrano Rose from the end of January to the middle of March, because they are shutting their eyes to the fact that the bloom, or fruition of any plant whatever, is not governed by any set period of time, but rather by the sum total of necessary warmth which it receives during such period.—M. VRAY, in *Journal des Roses*.

Rose Violette Bouyer (H.P.).—It is said that this variety originated from Jules Margottin, and it is not a difficult matter to accept the statement. It has the fine vigorous growth of the grand old favourite, but here the likeness ends, for Violette Bouyer is in colour a lovely white, usually suffused with the most delicate shade of pink. The flowers are very double, globular in form and very freely produced. Unlike many of the H.P.'s, the flowers of this open almost simultaneously, affording at once a grand sheet of blossom. It is several days earlier than its larger rival, Merveille de Lyon. It has also another advantage over the last-named, and that is in its fragrance. I can recommend it with every confidence to anyone desirous of obtaining a good Rose to cut from. I never have seen this Rose so lovely as it has been this year.—P.

Weeping Roses.—There is an indescribable grandeur about perfect specimens of these weeping Roses that I am surprised they are not more frequently seen. To those who have space I would recommend them to try a few this coming autumn. Cultivate them well, do not touch them with a knife, and in three or four years splendid heads will be formed. Imagine a *Félicité-Perpétue* or a *Ruga* upon a 6-foot stem with the graceful shoots reaching almost, if not quite, to the ground, and wreathed all over with the fragrant blossoms. To add a touch of brilliancy, some *Crimson Rambler* upon stems the same height would indeed make a most glorious display. There is not quite the same graceful style in this Rose as belongs to the Ayr-shires, but it makes up for it in colour. Alternate trees of *Crimson Rambler* and *Félicité-Perpétue* planted alongside a spacious promenade could not be surpassed for beauty.—P.

The Garland Rose (Hybrid Musk).—This is well named, its huge panicles forming a veritable garland of creamy white blossoms. The tiny flowers as they open are of a lively buff shade, changing to pure white as they develop. It is very interesting to see the two colours mingled upon the same panicle. This variety forms an ideal pillar Rose, rampant and graceful. The growths darting out here and there among the huge bunches of flowers take away all stiffness of outline unfortunately so common among pillar Roses. Possessing as we do such a Rose as this, one need not be at a loss what to plant as a fitting companion to *Crimson Rambler*. This variety and *Félicité-Perpétue*, with, perhaps, *Aimée Vibert*, form grand contrasts to the ever-popular Rose named. To obtain the best effects they should be trained to 10-foot iron stakes. When these are covered (and they will be in an incredibly short time) the grandest form in which to grow these Roses will be made abundantly evident.

Rose Reine Olga de Wurtemberg.—When ordering a number of Roses for planting in the autumn of 1896, one plant of the above variety was included in the list. Last year, owing to the drought, both it and the other sorts made but little growth, but they formed an abundance of roots and became well established by the end of autumn. This season top growth has been more proportionate, with the exception of the above-named variety, which has already outgrown its allotted space. It is a rampant grower, and is more suitable for planting to cover a rough wall, an arbour, or some situation where it could grow away in a half-wild state, when it would no doubt reward its owner with an abundance of its semi-double brilliant red flowers. It evidently doe

not like restriction, and other quarters will accordingly have to be found for the plant this coming autumn, and where it will feel more at home. For cutting it is of but little use except in the bud state. It is a charming Rose, for which a position such as has already been hinted at should be found in every garden, provided the necessary space is available.—A. W.

A noble climbing Rose.—Gustave Regis puts all in the shade here for glorious colour, its fine dark stems and foliage adding another distinction from other yellows. The description hardly corresponds with that of the note in THE GARDEN of July 23, but that may be from the situation it grows in. Here, on a rough wall 15 feet high, in full south aspect, it rambles about in the open orchard with hosts of others, including *Maréchal Niel*. On comparing the two—both grown outside—Gustave Regis has by far the richer colour, and if it does so well here (N. Derbyshire) it should become more popular. How beautiful these wall Roses have been, and no doubt will be again later on, as they generally are here. I could not help filling the box with *Celeste*, the loveliest of bud Roses, and growing away happily anywhere either in sun or shade.—Geo. BOLAS, *Hopton Hall, Wirksworth*.

Rose Homere.—A couple of years ago, owing to alterations in the kitchen garden, I had occasion to shift a lot of old standard Rose trees on to a piece of grass recently enclosed. Judging by the appearance of the stems, the plants must be twenty years old at least, and it seemed doubtful if they would stand disturbing. All had evidently been closely clipped back for years, so they were simply lifted and planted carefully, staked, and mulched. They have not had a knife near them since, and all have made grand heads that have been covered with bloom this season. Among them was a plant of this beautiful old variety, and my object in writing is to note what a grand thing it is when grown thus loose and unpruned. Hundreds of flowers in all stages of development are now open, and after the heavy rains the foliage is fresh and green, forming a delightful picture. Closely-pruned standard trees are not pretty, but these great heads are quite a feature in any garden, large or small.—H.

Rosa gigantea.—A flowering specimen of this species, says the Kew Bulletin, has been received at Kew from Mr. T. H. Hanbury, La Mortola, Ventimiglia, Italy, with the following information under date of April 26: "On Sunday I saw *Rosa gigantea* in full bloom on the façade of the Chateau Eleonore at Cannes, the residence of Lord Brougham and Vaux. The plant is growing in a box measuring, perhaps, 2½ feet by 1 foot by 1 foot, and I should say that this box must be entirely full of the roots of the plant. The colour of the buds reminded me of those of the Rose Wm. Allen Richardson, but under the strong sun it opens very quickly and looks almost white before the petals fall." *R. gigantea* was discovered in Burmah, on the Shan hills plateau, at 4000 feet to 5000 feet, by Sir Henry Collett, K.C.B., and also in Manipur, at an altitude of 6000 feet, by Dr. Watt. At first there seemed hopes that this fine climber would succeed on walls, &c., in sheltered places in Britain, but although several plants at Kew and elsewhere withstood—with comparatively little protection—the severe winter of 1890-1, that of 1892-3 killed all of them outright. At Kew it grows vigorously under glass, but, so far, has not flowered.

Rose Climbing Souvenir de la Malmaison.—It is interesting to see this climbing form of a grand old Rose flowering profusely this year. As it grew so freely as a young plant and never produced a bloom, it was feared that it was going to turn out a shy variety. However, this season plants left at pruning time with 8 inches or 9 inches of last year's growth are now yielding quantities of buds, which disposes of the doubt alluded to. Everyone knows the old variety, how free-flowering it is and how useful in autumn, but it may not have occurred to many that an effective arrangement of this Rose can be produced by

planting its climbing form in the centre of a large bed, surrounding it with a quantity of the old dwarf form. The centre plants could have the support of about 5-foot stakes, and the remainder of the climbing form be treated as bushes. Thus, instead of having a flat mass of blossom, one could obtain an almost pyramidal formation, which would be a very telling feature in the garden. As an additional attraction one could plant an outside bordering to this bed of that very beautiful sport of the old Malmaison, namely, *Kronprinzessin Victoria*, for its sulphur-white blossoms are very lovely, and an agreeable contrast to the shell-pink flowers of its parent would be obtained.—P.

Rose Hon. Edith Gifford.—This is one of the best of the Teas and a good Rose for any position. The white of the flower is relieved as it opens by a tint of rose, while either in the bud or when fully open it is an exquisite Rose. It is also a good grower, with handsome foliage and flowers profusely. Plants put out last November and cut quite down to within a couple of inches of the ground started well, and are now nice bushes a couple of feet in height and carrying a number of fine blooms. Many growers, having the idea that these Teas will not stand pruning, leave them after planting with all the small wiry spray as they come from the nursery. With plants from pots the harm is not so great, but

Rhododendron Nuttalli. From a photograph sent by Mrs. Lawrenson.

when they are lifted and every bit of soil taken off to save weight the roots cannot possibly stand the strain. Not only this, but even with established plants weak shoots must break weakly and all such spindly wood should be taken out. The safest plan is to get the Roses in as early as possible, and if cold winds or frosts seem imminent to mulch at one. Then, instead of leaving the heads to gradually die back cut them back to firmer wood at once, and in spring prune rather severely. This will lay the foundation of a good tree, and subsequent pruning will consist only in taking out weak wood that is not likely to flower well. There is no comparison between such plants and others left with the heads drawing away at the roots all winter.

Two useful early Roses.—Although very old-fashioned, the *Gallia* and *Damask* Roses give us several useful kinds for early cutting or for garden decoration. Two of the best and earliest are *Blanchefleur* and *La Ville de Bruxelles*. The former is a very free, hardy sort, yielding quantities of white blossoms. As it appears before *Mme. Plantier*, it comes in most use-

ful for cutting early. It is summer flower ing only, therefore the shrubby border is the best place for it. Good plants upon their own roots quickly increase in size, and by pegging down the growths a broad mass of it is produced, which when in full blossom is very effective. The other variety, *La Ville de Bruxelles*, would make an excellent contrast to the above, and flowers at the same time. Its blooms, so freely produced, are of a beautiful lively rosy pink, paler at the edge of the petals. Like most of its tribe, the flowers are very flat, but they are very double and last a long time. The French and *Damask* Roses are extremely free growing and hardy, but in many cases advantage is taken of this fact to allow the plants, as it were, to care of themselves. I think this is a mistake. Give them the same treatment as we afford our exhibition Roses, such as thinning the growths and manuring, then flowers and foliage of surprising beauty will be the result.—P.

TREES AND SHRUBS.

RHODODENDRON NUTTALLI.

THIS was introduced from Bhotan in 1859. In its native mountains it grows from 10 feet to 30 feet high, and is frequently found growing as an epiphyte on the trunks or limbs of large forest trees. It is one of the largest flowered and most handsome of all the Indian species. There is no difficulty in its cultivation. The specimen from which the photograph was taken has been in possession of the owner, Mr. James Thompson, J.P., of Macedon, co. Antrim, Ireland, for above four years, and has always been in an unheated orchard house, not receiving any particular attention. It flowered in 1896 and again this year. The photograph was taken by Miss A. Bland.

Azalea viscosa.—Since the middle of June and throughout the whole of July lovers of pretty hardy plants have been able to enjoy the white sweet-scented flowers of *Azalea viscosa* (L.), known as *Rhododendron viscosum* (Torr.). The bush reaches, as a rule, 2 feet to nearly 4 feet in height. It was introduced from Virginia in 1734, and seems to be rather overlooked now-a-days—wrongly, to be sure. There are numerous varieties, among which are *A. v. tomentosa*, with red flowers; *virens*, with glossy leaves; *seabra*, with rough leaves; *tardiflora*, or *serotina*, which flowers early in June; *purpurea*, with purple flowers; and *nitida*, with white flowers tinged with red.—*La Semaine Horticole*.

The Jerusalem Sage (*Phlomis fruticosa*).—Though the order Labiate is a very extensive one, very few members of it find a place among our hardy shrubs, and, indeed, those few must be regarded rather as of a sub-shrubby character. One of the most noticeable of all is the Jerusalem Sage, which is a decidedly striking plant, and one, too, that will hold its own and flower well even in dry, sandy and stony soils; in fact, under such conditions it forms a more lasting shrub than it does in a good moist soil, for though its rate of growth is under such conditions more rapid, after a few years it commences to decay. The Jerusalem Sage forms a somewhat open bush that reaches usually a height of 4 feet to 6 feet. The stout branches are clothed with rugose leaves of a peculiar hoary character, while the flowers, which are borne in whorls on the points of the shoots, are large and of a rich bronzy yellow colour. It blooms as a rule during two or three months of the summer.—H. P.

Solanum jasminoides.—This is one of the most beautiful of climbing plants, and yet as such one of the rarest. It is also much more hardy than many people suppose, and this ir-

districts where its hardiness may in some measure be open to doubt. Quite recently we have seen this exquisite climber in a Thames-side garden flowering freely over a wire archway, and in a position, moreover, that at high-water mark has more than once been covered with from 2 feet to 4 feet of water. The pure white trusses of its flowers are so beautiful amid the dark green of its somewhat shining leaves as to always attract notice when the plant is in flower. The position best suited to it is a warm, sunny spot, yet in such that it is not allowed to suffer through lack of moisture. In the garden referred to no special soil was given at planting, yet it would appear to have a preference for peat and loam in about equal parts with root moisture in summer. The other day we noticed a nice batch of *S. j. floribunda* flowering with great freedom in quite small pots in Messrs. Veitch's Chelsea nurseries, the mass of flowers very chaste and pure.

ORCHIDS.

DISA GRANDIFLORA.

It is remarkable how many exhibitors fail with this showy Orchid, while others less skilled in Orchid culture can grow it with apparent ease. There is no doubt that a good deal depends upon the position in which the plants are grown, and that there are houses in which it is quite impossible to cultivate it well. It is difficult to say why, for apparently one house may be as suitable as another, yet in one the plants go on and improve every year, while in the other they cannot be induced to thrive or increase. The most likely place is one where the temperature remains constantly low all the year round and the atmosphere is continually moist, though with plenty of fresh air moving about over the foliage. Such positions are, of course, not easily found, as the air currents in the majority of cases soon sweep away the moisture, and on hot, sunny days it is difficult to keep the house at all cool without shutting it up close and shading heavily. Shade the plant must have, as a matter of course, but light is also essential, and this is where many such houses are found wanting. A heavy, thick mat or some such substance is used, and this effectually bars the passage of light and to a certain extent air also. Many again err in pulling the plants about too frequently and at all sorts of unseasonable times.

The plants vary in their time of flowering, and any that are now in bloom may be repotted as soon as the flowers have faded. Earlier plants may go into a cold, shady frame, or even be stood out of doors for a time, and be repotted after a little ripening up. But ripening up must not be confounded with drying off, for to dry the plants at this time of year will do more to ruin them than anything else. The new roots that are produced now and a little later will serve to re-establish the plants after repotting. It is well to get away as much as possible of the old material from the roots, as they abhor nothing so much as a close, heavy, and sour condition. To prevent drying, lay the crowns on damp Sphagnum Moss while the specimens are being made up. The plant has a very fine effect in large deep pans of good width, especially if extra strong crowns can be procured. A specimen with ten or a dozen spikes has a very fine appearance. Single crowns may also be grown in 6-inch pots well drained, in a compost of two parts of Sphagnum Moss to one each of peat and loam fibre, adding crocks and charcoal freely in large or small lumps, according to the size of the plants.

If convenient, the pans may be surfaced with Sphagnum Moss, as this does away with the necessity for heavy waterings during late autumn and winter. Moisture, of course, is required even now, but if it can be provided or rather conserved by these means, it is much better than continually pouring the water on. Great care must be exercised when picking over the Moss for this purpose, for perhaps there is hardly another species of Orchid of which small snails are so fond. Even when not present in the pans, they find the young growths out by some instinct and do incalculable harm in a very short time. When growth is getting well away the plants require a great deal of water both at the roots and overhead, light sprinklings from the syringe several times daily being of great assistance in keeping down black thrips, their worst insect enemy. *D. grandiflora* is sometimes grown in prepared beds of compost in a suitable house, and in such positions the young offsets are very freely produced. When it can be induced to thrive in such a position it does remarkably well, owing to the freedom the roots obtain.

Saccolabium Blumei.—This lovely old plant is now in full beauty, the long cylindrical racemes of flower being grand, especially when seen upon small plants growing in baskets. These hung from the roof of a warm house thrive well, as they enjoy the light and free air circulation better than a stuffy, moist heat. Clean Sphagnum Moss and abundance of crocks and charcoal suit it well for compost, and no dry rest or cool treatment is necessary to induce it to flower.

Miltonia Moreliana.—This is handsome in its best forms, the bright rosy purple lip with deeper lines being most effective. The flowers appear singly and last well in good condition, the plants if healthy and well rooted carrying them until they fade. *M. Moreliana* is, botanically speaking, a variety of *M. spectabilis*, and one of the finest of Miltonias. It may be grown on rafts with a surfacing of compost, or in shallow baskets in peat fibre and Moss over good drainage. The colour of the foliage is usually pale yellow, but this is not a sign of ill-health.

Oncidium crispum aureum.—Flowers under this name come from R. Roberts. They appear to vary little from those of *O. c. flavum*, though the yellow tint is very rich and the individual flowers are large. Large spikes with many flowers of this variety have a bright and pretty effect, but, like the type, the plants are rather difficult to keep in health for many years. They abhor a close and heavy compost, thriving best as a rule on a raft or in a shallow basket suspended close to the light in the Cattleya house. The large spikes produced are very trying to the plants if left on until the flowers fade.

Maxillaria tenuifolia.—Small plants of this species, although they do not show the peculiar habit, always produce more richly coloured flowers. The number produced when the specimens are healthy is enough to make a showy plant, the rich dark red of the flowers showing up well against the deep green of the foliage. When rambling away, the pseudo-bulbs are not so strong, though the semi-pendent habit assumed is pretty. It is an easily-grown specimen in an intermediate house if potted or placed in basket, with equal parts of peat fibre, loam, and Sphagnum Moss over good drainage.

Odontoglossum Harryanum.—This is very fine this week, a plant having several flowers. The sepals and petals are almost entirely deep chocolate, only a little of the usual green tint showing, and the form is good and well displayed. Although *O. Harryanum* will go on and increase in size annually if well treated, it is a bad plant to bring back to vigour when once shrivelled by drying-off or over-flowering, many fine plants in their first year of blooming having

been ruined. The pots for this species may be of medium size, and the usual compost for *Odontoglossums* suits it. A little more warmth than the cool house affords answers best during the winter.

NOTES ON ORCHIDS.

Now that the days are shortening and the growth of many species approaching completion, it will be necessary to closely watch the shading. The blinds must never be left down a minute longer than is really necessary, and the foliage on many spring-flowering kinds being now hard more sun is admissible. The *Dendrobiums* must be pushed along now, running the houses well up by early closing and drawing the blinds at the same time. The aspect of the house has of course a good deal to do with the time of closing, but with houses running north and south, or nearly so, with shaded ends the safest time now is about 3 o'clock. Where the sun shines on the house later, owing to its aspect, it may be well to wait another half hour or so. The proximity of trees or high buildings will also influence the time of closing, of course. I like to give these plants a thorough washing with the syringe when very hot weather prevails, as the baskets or pans are usually small and do not catch much of the water. Besides this, the roots now can hardly be over-watered in such receptacles, as growth is very active and this makes a great demand upon them. The somewhat difficult *D. Macfarlandi* delights in this treatment, provided always the plants are well established and healthy in pots or pans of limited size. It is with these difficult kinds that the value of good sound peat is so pronounced; it allows of the plants being kept year after year in the same receptacles, the fibre gradually wasting away instead of falling into a soddened mass, annual top-dressings being used to keep the plants going.

In the Cattleya house we have been busy surfacing large old plants of *Laelia purpurata*, the late-flowering specimens being just at the right stage for it. The roots enter the compost more freely now than at any other time of year, and with the above may be classed *L. elegans* and *L. crispa*, also any of the late-flowering Cattleya Mossie not yet attended to. The old autumn-flowering *C. labiata* is commencing to push up the spikes and must be encouraged by ample moisture, as although the roots are not making great progress on the surface, those below in the compost are active enough. This is one of the most constant Cattleyas in existence and never fails to bloom profusely. *C. Dowiana*, on the other hand, is liable occasionally to miss flowering. The growths with me this season are very free, and there is every prospect of a fine bloom a little later. The sticky exudation from this plant has been very marked this year, and growers should keep this under by sponging if it appears at all likely to hamper the forming growths. Otherwise it does no harm and may remain for the purpose it was evidently intended for, the trapping of any chance insect that may be prowling on the growth. All small-growing plants, such as *Zygopetalums* of sorts, that are growing upon blocks of Tree Fern or dressed wooden ones should be examined now, and where the young pseudo-bulbs are getting away from the rootstock they should be pegged or wired down; a little fresh Moss may also occasionally be required. See, too, that they do not suffer from want of moisture, these little attentions making all the difference to plants of a naturally weak constitution. The nearly-related bulbous kinds, such as *Bolles*, *Pescatoreas* and *Warszewiczellas*, should now be growing freely in a shady, moist part of the house, and here, again, a little adjustment of the compost may be necessary. By no means pull the plants about if they are doing well, but a bit of Moss here or charcoal there may do good where a growth or tuft of growths is loose. Galeandras are thirsty subjects at this time of year, and must not be neglected as regards water. Whenever a house is fumigated or vaporised, these

plants may with advantage be placed therein, they being peculiarly susceptible to the attacks of thrips. There are other kinds, too, that are objects of their attention, including the lovely *Miltonia vexillaria* and *Colax jugosus*.

There is not much doing in the cool house except the ordinary routine work. The majority of the plants are growing, and must naturally be encouraged. *Anguloas* recently repotted will by now be rooting freely into the new material, and as it is important that good pseudo-bulbs be made early, no check must now be given either by lack of moisture or through draughts. Scale puts in its appearance occasionally, and must be kept under by careful sponging. *Bletias*, *Thunias*, and other Orchids of this nature that have been put out of doors should not be too rapidly dried, but the foliage allowed to fall gradually and naturally, performing its proper functions to the last and preparing the plants for their winter's rest.

Phalænopsis violacea.—This is a very lovely little Moth Orchid when well grown, the deep violet-purple on the inner side of the lower segment and the front lobe of the lip showing up the somewhat dead tint of the rest of the flower. There is a good deal of variation in the species, some forms having more colour than others, one pretty variety having very little purple about it. It is much more frequently seen and a better grower than most of the *Phalænopsids*, and succeeds in most places under the conditions usually advised for the genus. It is a native of Sumatra, and first flowered in England in 1878.

Brassavola acaulis.—Though not a showy species, the peculiar habit and flowers of this plant make it worth a place. The leaves are Rush-like, growing in tufts, the flowers appearing at the base of these. The sepals and petals are greenish, the lip pure white, occasionally fringed, as in *Epidendrum ciliare*. The plant cannot be said to be difficult to grow, yet the fact remains that in some collections where Orchids as a rule are well done this is a failure. It is not a free-rooting subject, and the roots are easily surfeited by too much moisture, this leading to their decay, the plants in consequence becoming loose and untidy. In order to prevent this, I fastened some plants to rough blocks and wired these down to baskets of suitable size, filling up with crocks and surfacing with clean Sphagnum only. The plants came away well and grew with freedom, flowering every season, and when I left them were fine healthy specimens. It is quite wrong to give them much compost, as the roots cannot obtain a hold of the pots or baskets through it. For the growing season on the Cattleya house suits the plants, and they may be rested a little cooler when well established.—H. R.

Pachystoma Thomsonianum.—The flowers of this rare and beautiful Orchid appear during this month, and it is a pity it is not more generally known, as it would help to brighten a rather dull season for Orchids. The habit is pseudo-bulbous, and the plant is rather a restless one, growing out of season often and keeping to no strict routine. The flowers appear several together on slender scapes and are white in the sepals and petals, the singularly-formed lip being spotted and otherwise marked with purple. They have a very chaste appearance while they are fresh, the deep purple showing up the pure white most beautifully. It is an African species, coming from the mountains of Calabar, and requiring purely tropical treatment all the year

round. The plants like abundance of atmospheric as well as root moisture, and also light dewings over the foliage when the house is closed for the day. The pseudo-bulbs being small and the plants not particularly vigorous, it is best not to give much in the way of compost. On trellised rafts with a little Sphagnum about the roots, or in small well-drained pans, the plants do well, and may be placed in the same temperature and house as the *Dendrobes* while growing. It was introduced in 1878.

FLOWERING CLIMBERS.

IN the springtide of the year many a delightful picture is afforded by hardy flowering climbers, such as the mountain Clematis and Wistaria. In the accompanying illustration we see a stretch of wall made beautiful by their countless blossoms, especially effective being the brick archway, its sharp outline half veiled by the flower-wreaths of the Clematis, through which is seen a distant garden vista, while the blossom-laden sprays have rambled upward among the boughs of an overhanging tree. The two climbers here represented associate charmingly with one another, the lavender pendent

A wall covered with *Clematis montana* and *Wistaria*.

bloom-clusters of the *Wistaria* being set off to the best advantage by the ivory-white flower-mantle of the mountain Clematis. Crude walls and ill-designed structures devoid of interest assume an aspect of beauty when swathed in trailing growth and floral tracery. Strong-growing climbers, such as the two already alluded to, soon attain large proportions and clothe a wide expanse of wall in a comparatively short space of time. It is when allowed unrestricted freedom of growth that the most picturesque effect is obtained, and a *Wistaria* rambling along the coping of an old wall or Clematis garlanding the sombre foliage of a Yew with trails of starry blossoms are infinitely more charming than the same plants when subjected to formal training. Balconies and verandahs can be rendered objects of loveliness for many a month by the help of flowering climbers. One I have in my mind where the mountain Clematis and *Wistaria* mingle their blossoms and the Banksian Roses bear their sprays of yellow and white flowers. Later on the purple Clematis *Jackmani*, which has threaded its way through the countless growths,

spreads its rich velvet hue over the greenery and tall white Lilies grow at the foot of the pillars, while in the autumn the Virgin's Bower (*Clematis Flammula*) fills the precincts with sweet perfume. There are many other ornamental climbers that may be utilised with good effect, especially in the south-west, where *Solanum jasminoides* grows freely, and will cover a house with its snowy flower-clusters in three or four years. Where it is not liable to be killed or seriously injured by severe frost, there is no more satisfactory climber, as it commences to bloom in May; this year, indeed, it was in flower before the end of April, and blooms throughout the entire summer and autumn, after retaining its blossoms as late as November. Where the *Solanum* is hardy, *Physianthus albens* will also grow vigorously and produce its white flowers in profusion, while *Stauntonia latifolia* and *Cianthus puniceus* may also be planted with satisfactory results. The well-known blue Passion Flower is a quick-growing and decorative climber, and is attractive both during its flowering period and when, later in the year, its golden orange fruits hang like fairy lamps among the dark foliage. It has also the advantage of being practically evergreen,

its old foliage being in most cases retained until shortly before the appearance of the young leaves in the spring. S. W. F.

Lantanas.—In the days when specimen plants were popular two or three of the more vigorous forms of *Lantana* were occasionally employed for the purpose, but of late years they have been almost completely overlooked, though a dwarfier and exceedingly free-flowering race has now sprung into existence. This class of *Lantanas* may be employed for various purposes, and they are very useful where a greenhouse or conservatory has to be kept gay at all seasons, as they are of easy culture and keep up a succession of blooms for some time, added to which they are widely dissimilar from most plants so employed, and the great changes in colour that the flowers undergo from the time of expansion until they fade render them additionally interesting. Planted out during the summer months, *Lantanas* will flower well and keep on till the autumn. Their propagation and culture are very simple, as in spring cuttings of the young soft shoots will strike root as readily as a *Fuchsia* if treated in the same way, and they will grow freely in ordi-

nary potting compost. Cuttings put in early in the spring should be potted off as soon as rooted, and directly they take hold of the new soil the tops must be pinched out; then, treated much as the general run of greenhouse flowering plants, they will branch out and grow away freely. Then as the season advances the neat little bushes become thickly studded with flattened flower-clusters, which present a bright and attractive appearance during July and August and well on into the autumn. In growing the Lantanas, too much shading must, of course, be avoided, but the one thing to particularly guard against is red spider, which is very liable to attack the under sides of the leaves, and once it has effected a lodgment thereon is very difficult to eradicate. A good circulation of air as distinguished from direct draught and a liberal use of the syringe will as a rule serve to keep the plants clean. At Kew the Lantanas have for some years formed quite a summer feature in No. 4 greenhouse, but though they are often greatly admired, their culture does not seem to make much headway in gardens. Neat little plants of many varieties that differ widely from each other in the colour of their flowers can be obtained at a cheap rate from several of our nurserymen.—H. P.

ORCHARD AND FRUIT GARDEN.

TREATMENT OF YOUNG VINES.

WITH a view to getting as much as possible out of young Vines the first season, somewhat early closing and scant ventilation are practised during the summer. It is quite advisable, too, and good practice, for though rather shorter-jointed rods may be produced under less hastening conditions, it is a fact that short-jointed canes do not always mean a more regular start than longer ones. But the foregoing treatment must not be unduly prolonged, and after the end of July the growth made is not likely to become sufficiently well ripened to remain at the winter's pruning. After this date, then, the aim of the grower must be to ripen up the growth already made, and if the main rods are not shaded or crowded by foliage, a rather free lateral growth is desirable. To suddenly alter the conditions that have obtained during the summer and to throw open the houses at once would do more than anything to defeat the end in view. It is just possible that it may cause a check to growth, and this is not desired, for development depends as much upon the sap being kept moving as upon the admission of sun and air. When the time comes for the Vines to go to rest they will do so, and the more active the sap is at the end of the season the better, the leaves coming off freely in the hand when touched, and the eyes at the base of each swelling up properly. Growth checked by sudden inrushes of cold air will keep green, and the foliage will remain on until midwinter. No one needs to be told which kind of growth is more likely to be satisfactory the first season or to continue longest in proper condition. As in many other phases of gardening, the old saying "the more haste the less speed" is applicable to the ripening of the wood on young Vines. I like to see them grow quickly and produce large leaves, thick tendrils, and big buds at the base of the leaf-stalk. As a means of regulating the flow of sap to the buds individually, the plan of frequently pinching the main rod as it is made is not so much practised as it deserves to be. There is no check to growth in the process, and the difference in length of stopped and unstopped rods is practically none.

The plan I follow is to cut down the young Vines to hard wood in winter, whether this

comes to the level of the wall plate or below it, plant when the Vines have made about 4 inches to 8 inches of growth, and push them on as rapidly as possible. Sometimes a slight check will be noted, especially with Vines not too well rooted, but when the roots catch up to the growth, so to speak, they are soon off again, and after this all is plain sailing, as a rule. When the young growth is about a yard in length, pinch the point out. It must not be cut back, or a swollen joint will result. Just take the very point out of the shoot, and this will be a sufficient check to the sap to help the lower buds to swell. It matters little whether the second or first lateral is now taken on as leader, but I have a slight preference for the upper one. When another yard or thereabout is made, the same stopping is necessary, and this should go on until the Vines have filled their space. A straight, well-furnished rod of even thickness throughout will be the result of this treatment, and during the first season it will easily climb an 18-foot rafter. There is a great difference in rods so made and others given their heads from the first, these, as a rule, being much longer jointed, with a greater difference between the upper and lower portions. As mentioned above, laterals that have been rather closely pinched during the summer may now be allowed to ramble a little, but there is no gain in letting them run wild. A tangled mass of lateral growths, with leaves twisted among each other, is not needed. What is required is enough growth to keep root action vigorous without crowding. By the time the leaves have fallen about November the house should be thrown entirely open and pruning may take place. Some growers practise half-pruning early, but, beyond letting a little light into any plants that may be in theinery, I fail to see what good it does, especially in the case of young Vines. The longer in reason the foliage remains on these the better the rods develop. If any suspicion of insects exists, the rods should be thoroughly cleaned in winter at the same time that the house is put in order, but the stupid scraping and painting with all kinds of rubbishy nostrums are as unnecessary as they are dirty and unpleasant in practice. Proper cleansing and the application of approved insecticides are, of course, necessary with neglected Vines, but not with young Vines in new or clean houses.

Grape Lady Hutt.—I do not know what may be the opinions of other growers regarding this Grape, but the more I become acquainted with it the more favourably impressed am I with it. I find it succeeds admirably in the lateinery with Lady Downe's and other heat-loving varieties, the treatment afforded the latter seeming to suit it exactly. I have but one rod, which, until the present season, did not occupy the best of positions, but owing to its succeeding so well and the appearance and flavour of the Grape being so much appreciated, a rod of another variety was cut away to make further room for it. The Vine has in consequence been much benefited, and will, I hope, carry a full crop another season. This year the crop consists of eight medium-sized bunches, the berries of which are now stoning. The berries grow to a large size, in fact almost as large as those of Gros Colman, and remain in sound condition well into January. The colour is a greenish yellow, but if the foliage is drawn on one side, so that the berries can get the benefit of all the light obtainable, they lose the green tint altogether. I consider it an extremely valuable Grape for January use, and the fact of its being a white variety renders it doubly so, as but few if any Muscats then remain for use. By growing Lady Hutt there is no reason why late white Grapes should not be had in the two first months of the year, if not later,

and although not equal to the Muscats, it is certainly richly flavoured when properly ripened, and therefore deserving of extended cultivation.—A. W.

Strawberries in Hampshire.—The season now closing has been a good one, and as the weather kept fine for picking and marketing, growers have not much to complain of. A fair average crop has been secured. The work of clearing off all the plants that are exhausted, now claims attention, and the land thus set free is at once planted with some kind of winter crop. The preparation of the soil and the planting of new beds need pushing on, for if not got in early there is no chance of a crop the first year, the finest fruits being usually gathered the first year after planting, and the largest crop the second year, and after the third the plants are generally grubbed up. In this locality growers of large quantities have to rely on the railway for transit, and for this reason alone the old well tried Sir Joseph Paxton still holds foremost place, for although Royal Sovereign is earlier, larger, and of very good appearance, it does not travel like Sir Joseph, and I doubt if any sort yet raised can supercede it, for the conditions under which Strawberries are grown, packed, &c., are so different from those of private gardens, that a variety which is first class for pot culture or open air if gathered in punnets and hardly touched until laid on the dessert dishes would be practically useless to the market grower who had to send his fruit long journeys by rail. Although many may think that market growers are prejudiced against new things, I can assure them that no class is more alive to the importance of keeping pace with the times by growing anything that is really an improvement on the old. They, however, do not hastily discard old varieties until they are fully assured that they have got something really superior, and that is the only reason why they stick to Sir Joseph Paxton as the main crop variety.—J. GROOM, Gosport.

MILDEW ON PEACHES.

CAN you tell me why so many of the early Peaches in my orchard house go mouldy? The mould on the Peach starts opposite to the stalk and often before the Peach is ripe. On the sound side the flesh will not leave the stone. The house is not heated and this is an early variety with a good crop on, but quite half were mouldy.—QUEDGELEY.

* * * Evidently a case of mildew. This fungus is liable to attack the growth and fruit of some varieties of Peaches and Nectarines more than others, and some positions are more favourable to an outbreak and spread of the disease than are others. In many instances the leaves and points of the shoots are badly crippled by mildew and affected fruit neither swells nor ripens properly. As far as "Quedgeley's" present crop is concerned there is no remedy, but it ought to be possible to prevent future attacks. After the fruits are gathered syringe the tree and then well coat branches, shoots and leaves with flowers of sulphur. Leaves as they fall and all prunings should be removed and burnt. If the tree is not in a satisfactory condition at the roots and it is just possible the border at that particular part may be in a soured condition, take this in hand before the leaves fall in the autumn, removing much of the old soil, relaying the roots after they have been pruned in a fresh loamy compost. Most nurserymen and seedsmen can supply recipes for mildew, or if "Quedgeley" would prefer to prepare a solution for himself the following would answer: Take half a pound each of powdered quicklime and flowers of sulphur, mix these into a paste with water, stir this into half a gallon of water, and boil for half an hour. Allow this solution to cool and settle, and then pour off the clear liquid, storing it in bottles, duly corked, for future use. When using, add a quarter of a pint to three gallons of soft water, and apply through a syringe in the form of a spray. Trees previously affected by mildew ought to be sprayed with the solution of lime and sulphur or other somewhat similar

preparations before active growth commences in the spring, continuing spraying at intervals of a fortnight or so till the foliage is fully developed, ceasing before the fruit is far advanced in growth. Warm evenings are the best time for applying these remedies. A stagnant atmosphere and late and reckless ventilating are frequent causes of mildew attack. While the foliage is tender it should not be exposed to a rush of cold front air, which is apt to bring germs of mildew with it. Up till the end of May it ought to be possible to keep the temperature low enough by opening the top ventilators only, commencing with a chink soon after the sun strikes the house and adding more as the temperature rises, in advance of rather than after a considerable increase of heat. In this way a genial growing atmosphere is maintained and all rushes of cold air avoided.—W. J.

NOTES ON GOOSEBERRIES.

The fruit here is much later than usual, but very fine. From plants trained on an upright trellis and rather long pruned I have been taking splendid fruits of Berry's Early Kent, a variety that is excellent for almost any form of training and soil. It is a wonderful bearer, even in positions not first-rate for its culture, while the flavour when fully ripe is distinctly good. There is a disposition among growers of this useful fruit on trellises or walls to prune too closely, in consequence of which the fruit is none too freely produced, nor is it so fine. There is nothing gained by cutting in closer than about 3 inches, and where the shoots are exceptionally strong they may be left longer than this with advantage. The shoots that come from the lower part of these laterals may be reserved until they have made about 8 inches of growth, then pruned back, keeping the sub-laterals closely pinched afterwards and rubbing some out entirely. Then at the winter pruning there is a choice of plenty of good buds to prune back to. Much of the old wood that has fruited may be taken out in autumn, giving that left the advantage of light and air. For bushes, too, this cutting out of fruiting wood is not sufficiently practised, and instead of a nice open tree, that one may get the hand into without fear of the spines, dense bushes are the outcome, which get larger and thicker annually, and from which it gets increasingly difficult to gather the fruit. Another richly flavoured kind just coming in is the Rough Yellow, an old and well-known sort, very useful for dessert before the large kinds, as a rule, are in. Of these latter, many of large size and good flavour are obtainable, one of the finest and earliest being Keepsake. The fruit of this is smooth, green, with lighter streaks, full of pulp, and with moderately thin skin. Angler is not quite so large, but of good quality, while later excellent kinds in this colour will be found in Telegraph and Thumper, the former especially free-bearing. The grand old Warrington is excellent as a late-keeping red sort, while larger and equally good fruits early in the season may be gathered from Rifleman and Whinham's Industry. These Gooseberries make excellent additions to the best dessert, and yet may be grown by amateur or cottager with the greatest ease.

Suffolk.

H.

Strawberries.—The long protracted spell of cold, sunless weather in June delayed the ripening of the fruit so much, that what looked like being a very early season was converted into a late one, for whereas in Jubilee year the best of the fruit was gathered in June, it was not until July this year that any fruit was fit for market, at least in the open fields. Not only were the days sunless and nights cold, but the continual rains caused the plants to carry an exceptional heavy crop of foliage as well as a heavy crop of fruit. A good deal of what should have been the finest fruit was spoilt by slugs or rotted on the ground. With the month of July came a sudden and welcome change to brighter and drier weather, and a large quantity of good fruit has

been sent away. The season will probably last considerably longer than during several of the preceding years. As the soil retained the moisture long enough to swell off the late fruits, I have not yet been able to get any correct reports as to how the newer sorts of Strawberries have been standing the test of travelling long distances by rail, but in my own immediate locality the fruiterers still give the preference to Sir Joseph Paxton as the best of all sorts, as the fruit turns out of the boxes or baskets as fresh and firm as if gathered from the plant. Royal Sovereign, although specially fine, did not travel nearly so well, and if kept until the second day was useless. The wet season rendered the fruit very tender and watery, and not nearly so satisfactory as it was from plants grown in pots. Making such large foliage, the plants need double the space between the rows. Royal Sovereign evidently needs a drier season if grown as an open field crop. If gathered in punnets it is grand, fruits each over two ounces being plentiful.—J. GROOM, *Gloucest.*

SOCIETIES AND EXHIBITIONS.

NATIONAL CARNATION AND PICOTEE SOCIETY.

CRYSTAL PALACE, JULY 27.

The original date was a week earlier, but the incidence of the season, and especially the prevalence of a low temperature at nights, had so retarded the development of the flowers, that it was found necessary to postpone for a week the exhibition; but even then the majority of the blooms were far from their best. Still, as is usually the case, there was a good representation of the leading sections, though there was a lack of that fine development which usually accompanies a favourable season. The nave of the Crystal Palace, with the awning overhead tempering the heat, is an ideal place for an exhibition of Carnations, as the flowers are always seen to the best advantage. What blooms were staged were mainly from the southern growers, for the most of those of northern growth were not sufficiently advanced. As far as the Carnations were concerned, the bizarres and the flakes fell below the average of quality we have been in the habit of seeing at this exhibition, but many of the selfs, the yellow grounds, and fancies were particularly good. The showy self varieties were most attractive, and the class for six blooms of a self Carnation of one variety, which did not find a place in the published schedule, was perhaps one of the most striking features in the whole exhibition, about twenty half-dozens of various colours being staged.

Mr. Martin Rowan, Manor Street, Chelsea, won the first prize for the best twenty-four blooms of flaked and bizarre Carnations, and his success is all the more satisfactory, seeing his flowers are grown so near to the centre of London. Mr. Rowan has been a most successful grower and exhibitor for many years past, but all his triumphs have been won with blooms grown within the area of smoky London. His best scarlet bizarres were Admiral Carzon and Robert Houlgrave; crimson bizarres, Master Fred and J. S. Hedderley; pink and purple bizarres, William Skirving and Sarah Payne; purple flakes, Gordon Lewis and George Melville; scarlet flakes, Constance Graham and Sportsman. Mr. J. Douglas, Great Bookham, was second. There were five stands of twelve blooms, Messrs. Thomson and Co., Sparkhill, Birmingham, taking the first prize here with Robert Houlgrave, Lord Salisbury, Master Fred, Guardsman, Sportsman, Magpie, Gordon Lewis, Vulcan, Mentor and Mrs. May, Mr. F. A. Wellesley being second. There were nine collections of six blooms, and Mr. A. R. Brown, Handsworth, Birmingham, was awarded the first prize, Mr. F. Hooper, Bath, the second, and Mr. Geo. Chaundy, Oxford, the third. Mr. Brown grows his flowers in one of the smokiest parts of a manufacturing district in Bir-

mingham. There were three collections of twenty-four self Carnations, but not necessarily distinct. Here Mr. C. Blick, gardener to Mr. M. R. Smith, Hayes, was first with a collection of brilliant blooms, those of a maroon shade being Sir Beveys, Friar Tuck, and Sir F. Drake; crimson and scarlet, Mrs. Gray Buchanan and Firebrand; rose, Mrs. A. Norman, Enchantress, Joan of Arc and Exile; yellow, Cecilia, Falcon and Miss Julia Harbord; white and blush, Kelpie, Hildegard, Helmsman, Purity, and Cordelia. Second, Mr. Douglas, whose blooms were very good, but unnamed. Mr. C. Turner was third, his finest blooms being Little John, Sir Guy, Germania, Duchess of Fife, G. L. Mine and Rose Unique. There were seven entries for twelve blooms, Messrs. Thomson and Co. taking the first prize with very fine flowers of Her Grace, Exile, Mrs. Eric Hambro', Percy Conquest, Ruby, Germania, &c. Mr. C. Phillips, Bracknell, Berks, was second. There were as many as twenty entries of six varieties, Mr. A. R. Brown taking the first prize with really superb blooms of Royalty, a very fine deep rose self; Mrs. Eric Hambro', Miss Audrey Campbell, Mrs. J. Douglas, Negress, and a seedling. Mr. W. Garton, jun., Woolston, Southampton, was second. Next came the fancies, a fancy Carnation being anything which cannot be classed in any of the foregoing sections or among the Picotees. Here some very fine and striking blooms were staged. In the class for twenty-four fancy Carnations, Mr. M. R. Smith was first with a magnificent collection mainly of new varieties. The most striking were Aglaia, Muleteer, St. Gatien, The Cid, Merry Duchess, Goldilocks, Elaine, Renegade, Maid of Honour, Zingari, Alexandra, Electra, Eothen, Allegra, Fairy Guinevere, Persimmon, Lord-Lieutenant, Don Carlos, and Hidalgo. Mr. C. Turner was second with smaller flowers of excellent quality. Mr. A. J. Rowberry, South Woodford, was first with twelve fancy Carnations, his chief blooms being Cardinal Wolsey, Orestes, Monarch, in two distinct forms, Dervish, &c. Mr. C. Phillips, Bracknell, Berks, was second; his leading flowers were Miss Arkwright, George Cruickshank, Cardinal Wolsey, and seedlings. There were nearly twenty entries for six blooms, Messrs. Thomson and Co. coming to the front with the following in very fine character: Cardinal Wolsey, Voltaire, Golden Eagle, Monarch, Miss M. Hill and Socrates. Mr. J. W. Foulkes, Chester, was second with Voltaire, Cardinal Wolsey, His Honour, and May Queen as his best flowers. An interesting supplemental class was for six self Carnations of one variety, in which there were many entries, the first prize falling to Mr. Martin R. Smith, who had Cecilia, a large pale yellow self; Mr. J. Douglas was second with Mrs. Eric Hambro', a white self; and Mr. C. Phillips third with Regina, also a yellow self. A further supplemental class was provided for six fancies of one variety, Mr. M. R. Smith taking the first prize with Hidalgo; Mr. A. W. Jones, Handsworth, was second with Golden Eagle; and Mr. J. Douglas third with Perseus. There were fifteen entries. Next came the classes for single blooms, in which a considerable number are staged, the judges selecting the best. Of s.b. Carnations the best was Richard Monk, a fine new variety from Mr. R. Sydenham, Robert Houlgrave and Robert Lord following in the order of merit. Master Fred, also from Mr. Sydenham, was the best c.b., J. D. Hextall coming next. That fine p.p.b. William Skirving took all the prizes in this class. The best p.f. was Gordon Lewis, from Mr. M. Rowan, followed by George Melville and Magpie. The best s.f. was John Wormald, a new variety, shown by Mr. Sydenham; Sportsman came next. The leading r.f. was Mentor, from Mr. Brown; Mrs. Rowan following next in order. The best white selfs were Mrs. Eric Hambro', The Bride, and Cristabel; the best rose, Exile, Royalty, and Perfection; the best scarlet, James Douglas, The Cadi, and Lady Hindlip; the best maroon, Uncle Tom, Manxman, and Labby; the best yellows, Miss Audrey Campbell, Miss Wilmot, and Regina; and the

best buff, Mrs. Reynolds-Hole (finely shown by Mr. C. Turner), The Dyak, and Midas. The best fancy was Voltaire, followed by Monarch, Eldorado, and Cardinal Walsey.

PICOTÉES.

These are always an attractive section, and they were generally better in quality than the bizarre and flaked Carnations. Mr. C. Turner had the best twenty-four, the leading flowers being Brunette, Mary, Clio, Duchess of York, Madame Richter, Favourite, and Mrs. Payne. Mr. J. Douglas was second; he had Ganymede, Cassandra, Mrs. Chancellor, Harry Kenyon, Clara Penson, Nymph, Zerlina, Mrs. Ricardo, Mrs. Beswick, Constance Heron, and Fortrose. Messrs. Thomson and Co. had the best twelve varieties, Mr. F. A. Wellesley was second, and Mr. Weguelin, Teignmouth, third. Mr. A. R. Brown had the best six; Mr. Cartwright was second. The stands of twelve yellow ground Picotées brought some fine blooms, and they are always greatly admired. Mr. M. R. Smith staged a superb dozen, having in the finest character Duchess Lily, Badminton, Hygeia, Lady Bristol, Dinorah, His Excellency, Wanderer, Duke of Alva, Volage, Vampire, Edith, and Fashion. Mr. C. Turner was second; his finest blooms were The Gift, May Queen, Vespasian, Mrs. Douglas, Mrs. Gooden, and Golden Eagle. There were nine stands of six varieties. Mr. G. Chaundy, Oxford, was first, Messrs. Thomson and Co. second. Of single blooms of Picotées there were many. Isabel Lakin was the best heavy red; light red, Mrs. Gorton, Thomas William, and Lena; heavy purple, Medhurst's seedling; light purple, Harry Kenyon and Somerhill; heavy rose, Madeline, Lady Louisa, and Little Phil; light rose, Rosie Sydenham; heavy scarlet, Mrs. Sharp, Duchess of Albany, and Mrs. A. R. Brown; light scarlet, Favourite and Fortrose; yellow ground, Wanderer and Mrs. R. Sydenham. The premier bizarre was s.b. Admiral Curzon, from Mr. Rowan; the premier flake, s.f. Flamingo, from Mr. J. Douglas; the premier self, Cecilia (yellow), from Mr. M. R. Smith; and the premier fancy, Hidalgo, from the same. The premier heavy edged Picotée was Clio (scarlet), from Mr. C. Turner; the premier light edge, Somerhill (purple), from Messrs. Thomson and Co.; the premier yellow ground, Mrs. Douglas, from Mr. C. Turner.

Seven classes were set apart for exhibits of undressed flowers, and they were generally well filled, a large number of blooms being staged. At the luncheon Mr. Martin R. Smith made an appeal to the representatives of the gardening press to give a greater prominence to these classes than they had hitherto done, for, as he stated, they operated as a kind of introduction to the more important competitive classes, and amateur growers were induced to attempt something in the classes in which dressed flowers are admitted. It may be said of these classes that they were all well filled, but with few exceptions the flowers were small and lacking in symmetry. The principal prize-takers were Messrs. F. Hooper, W. Garten, Jun., J. W. Foulkes, S. F. Solley, J. Loredor, E. Charrington, W. L. Walker, S. A. Wendt, and H. Lloyd. Some of the flowers were unnamed.

There were classes for plants in pots. The only group, filling a space of 50 feet, came from Mr. M. R. Smith, and it contained some very fine new varieties, such as Helmsman, white; Her Grace, blush; Zelia, white; Triumph, crimson; Quentin Durward, pale scarlet; Godefroy, soft scarlet, with some yellow grounds. The best group of 30 square feet came from Mr. J. Douglas. He had some very good varieties, also selfs and yellow grounds. Mr. E. Charrington was second. Mr. M. R. Smith had the best twelve specimens in pots, and Mr. J. Douglas was second. They were all well-grown and bloomed plants. The best single specimen was Golden Eagle, from Mr. M. R. Smith. Mr. Douglas was second with Saul, a yellow self.

Floral decorations with Carnations comprised a dinner-table, the first prize going to Mr. H. Rogers, Woodbridge, who employed sma-

blooms of pink Carnations on a centre and two sidepieces arranged with appropriate foliage. The Morters Stores, Ltd., Norwood, was second with a heavier arrangement. They had pink and crimson Carnations, with appropriate foliage. There were also classes for ladies' sprays and button-holes. Many were staged, but it cannot be said they taught anything new or novel in this way. The Martin Smith special prizes for Carnations from the open border brought, as is usual, a good competition. The best bunch of a self-coloured variety was Jim Smyth, from Mr. H. G. Smyth, Bloomsbury, a brilliant scarlet of fine quality. Mr. Collins, Woodbridge, came second with Miss A. Campbell, yellow self, and Mr. E. C. Goble third with Duchess of Fife, soft pink. Mr. J. Enston, gardener to Mrs. Whitbourn, Great Gearies, was first with six bunches of self-coloured Carnations, staging very good varieties, but unnamed. Mr. E. C. Goble was second and Mr. H. W. Weguelin third. With nine bunches of flaked bizarres or fancy Carnations Mr. Weguelin was placed first, Mr. Enston second, and Mr. W. L. Walker third, all unnamed.

SEEDLINGS.

A large number of new varieties were staged and certificates of merit were awarded to the following from Mr. Martin R. Smith: Cecilia, yellow self; Goldlocks, Enchantress, salmon-scarlet self; Grand Duke, scarlet self; Benbow, apricot self; Edith, y.g. Picotée; Etna, bright scarlet self; Lady Bristol, and a dark crimson-maroon self named Lady Frances Scott, from Mr. E. Charrington.

On this occasion there was but little of a miscellaneous character in addition to the show. Mr. H. Eckford, Wem, Salop, staged fifty varieties of Sweet Peas, prominent among them the new varieties of the present year, Duke of Westminster, Faeination, Othello, Mrs. Dugdale, and the Hon. P. Bouverie being particularly fine. Messrs. W. Cutbush and Son, Highgate Nurseries, had an effective stand of bunches of cut flowers, Malmaison and other Carnations, Sweet Peas, &c., and Mr. J. Douglas had a table of cut blooms of his new and other choice varieties.

Royal Horticultural Society.—The next meeting of the society will be held in the Drill Hall on Tuesday, August 9. The committees will meet at noon, and at 3 p. m. a paper on "Water Lilies" will be given by Mons. Latour Marliac.

BOOKS.

WHERE WILD BIRDS SING.*

THE author wrote this little book in the desire to encourage the study of Nature, which is too much neglected or wrongly imparted in the training of the young. He has been a close observer himself all his life. He writes mainly about birds, but few things seem to have escaped his notice in insect, animal, leaf and blossom. The book seems well calculated to fulfil its object in inviting to the systematic observation of natural things. A chapter is devoted to each month of the year, and this seems the most natural way. Some of the things recorded are, of course, of common knowledge, but bear repeating, and there is much that is new to the ordinary observer, and nothing that is not interesting.

The weather in West Herts.—A warm week, the highest day temperatures in shade ranging between 70° and 77°. The night preceding the 26th proved an exceptionally warm one, the thermometer exposed on the lawn only falling to 58°, which with two exceptions (1893 and 1895) is the highest minimum reading registered by this thermometer in any part of the year

* "Where Wild Birds Sing." By James E. Whiting. Sydney C. Mayle, Publisher, Hampstead, N.W.

during the past thirteen years. In contrast to this high night temperature it may be stated that on two previous nights during the week the same thermometer fell to within 7° of the freezing point. At 2 feet and 1 foot deep the ground is at the present time respectively 2° and 4° warmer than is seasonable. Rain fell on three days during the week, but only to the aggregate depth of about a tenth of an inch. Indeed, so dry has the soil become, that no rain water whatever has come through either percolation gauge for nearly a fortnight. On the 24th the sun shone brightly for 13½ hours.—E. M., Berkhamsted, July 28.

— A week of changeable weather as regards temperature. For instance, on the 29th ult., the highest reading in shade was only 56°, while on two other days it reached 78°. Several of the nights were very cold for the time of year, and on that preceding the 31st the exposed thermometer showed a reading only 3° above the freezing point. There occurred a great range between the lowest night and highest day temperatures, the difference on two occasions being over 30°. At 2 feet deep the ground is now about 2°, and at 1 foot deep about 3°, above the average. Rain fell on but two days during the week, the total depth amounting to less than a quarter of an inch. On the 31st the sun shone brightly for 13½ hours, but the record for the 28th and 29th taken together was less than half an hour. During July the days were, as a rule, warm, while the nights, on the other hand, were usually cold. Indeed, on eight of them the thermometer exposed on the lawn registered readings from within 7 to 3° of the freezing point. Rain fell on but seven days, and to the total depth of less than three-quarters of an inch, or about one-fourth the average quantity for the month. It was not, however, quite as dry as the same month last year. Taking June and July together, the rainfall at Berkhamsted was, with the exception of 1868 and 1887, smaller than in the same two months for over forty years. The sun shone on an average for about one hour a day longer than in an average July.—E. M., Berkhamsted.

NOTES OF THE WEEK.

Carnation Princess Charles of Denmark.—Among the border kinds this is an excellent white self of capital constitution and free flowering. As a comparatively dwarf kind also this is worthy of note, while the petal is of good substance and fine in form.

Silene alpestris is now carpeted with its snow-white blossoms that produce so pretty an effect in the garden in its broad, spreading patches. It is one of the most freely flowered of the evergreen alpine class, and as such quite content in ordinary garden soil.

Sidalcea malvæflora Listeri.—The deeply-notched pink flowers of this plant render it most attractive in the border, where it is now in bloom. An easily-grown plant, of neat habit and producing its elegant blossoms freely are among the points that make it worth a place in collections of hardy things.

Pentstemon heterophyllus.—This is one of the neatest as it is the showiest of the dwarf Pentstemons; a plant, however, that would appear to delight in very warm and sandy soils. Quite dwarf bushes of it are now loaded with a profusion of lilac-blue flowers, and there is also a sort of metallic rose tint that renders this a very beautiful kind.

Linum arboreum is one of the prettiest of the hardy species, covered for a long time during summer with bright yellow cup-shaped blossoms on a neat, sub shrubby, compact-growing bush. It is a good border plant, and even better in the rock garden where more efficient drainage is usually at hand. Being so easily raised from seed, it may be grown quite freely with little cost.

The Burgundy Rose.—The pretty little Rosa burgundica has been very pleasing here this summer. The season has been rather a trouble-

some one for some Roses on this dry soil, but the watering necessary to keep some of the alpinas alive has suited the Burgundy Rose, which has delighted me with a considerable number of its neat double flowers. Many of these dwarf Roses are very interesting.—S. ARNOTT, *Rosdene, Carselthorn, by Dumfries, N.B.*

Patrinia rupestris.—Under this name there are two plants said to be grown, one being *P. intermedia* and the other *P. sibirica*. I must confess to being unaware which of these is the name of *P. rupestris* occasionally seen and seldom attractive. At Kirkconnel there is a good specimen which surpasses those usually found in gardens, and is rather a favourite from the profusion of small white flowers it produces. These are found useful for cutting.—S. ARNOTT.

Heuchera sanguinea grandiflora.—The striking beauty of this plant was again exemplified by some sprays in Messrs. Barr's group at the recent meeting of the Royal Horticultural Society. Taller in growth apparently than the original kind, it is equally free flowering, and what is of more importance still is the exceeding brilliancy of the flowers. These are so rich in colour as to leave the original a long way behind. It is to be hoped so marked an improvement will soon become plentiful.

Anemone japonica alba.—The earliest days of August, or in reality the first day of the month, saw the opening of the first flower of the above useful border plant. From the present time to the end of October this plant will yield an unceasing supply of the pure white and much-prized blossoms. Such profuse flowering in the best perennials is indeed a gain, the more so when in one species we have a trio of useful and beautiful subjects, this group of Japan Wind-flowers alone giving three distinct shades of colour.

Carnation Mephisto.—It is impossible when viewing border Carnations to refrain from comparing the different habits of the plants. Too frequently the general view is lost by noting a flower of more than ordinary size, beyond which, perhaps, there is little either of form or colouring to recommend it. In the above variety not only is there a decided colour, but good form with great freedom. More than this, the perfectly erect habit of the variety assists materially in the display, as every flower is thus seen to advantage.

Romneya Coulteri.—The lovely pure white satiny blossoms of this handsome plant are ever welcome, as few things are so strikingly beautiful and so chaste; indeed, the large blossoms are among the most exquisite of those of flowering plants, so delicate is the glistening purity of the large-petalled blooms of this fine Poppywort. A fine flowering group of this Californian plant would be difficult to excel, and in those favoured localities where the hardness of the plant is assured, nothing can surpass it in stately beauty. Some lovely plants in bloom were brought to the Drill Hall a week ago by the Messrs. Barr and Sons.

Campanula lactiflora.—One of the most showy of the taller border Campanulas is that grown and sold under the above name. Judging by the term itself, the plant should possess flowers of a creamy white, and such a plant, possessed also of the fine free-flowering habit as the one now referred to, would make a good display in the border at this time. The plant usually sold as the typical species is, in truth, *Campanula lactiflora cerulea*, one of the most freely branched of all the Bellflowers. Usually it is 4 feet high or so, and when given room for development, an extremely showy subject. This is also known as *C. celtidifolia*.

The scarlet Turk's-cap Lily (*Lilium chalcedonium*) is one of the showiest of all garden Lilies. The exceeding brilliancy of the flowers, which are of an intense glistening scarlet or vermilion shade, surpasses almost all others in this respect. In strong and rather clayey loam, freely intermingled with a marly gravel from the magnesian limestone formation, this fine Lily

proved most successful, being stronger and more vigorous than in any peaty bed, or with mixtures of loam and peat, which are frequently recommended for it. When well grown the plant is fairly robust, and will produce as many as eight and sometimes more of its richly-coloured flowers.

Fuchsias at Chelsea.—A very gay and pretty sight at the present time is largely composed of Fuchsias in one of the greenhouses at Messrs. Veitch's nursery at Chelsea. The plants are grown in large pots, and, with no stopping of any kind, are allowed to run up for several feet. A couple of these Fuchsias placed one on either side of one of the principal rafters and trained to the ridge throughout the entire length of the house make a very pleasing arrangement now that the plants are in full bloom. There is no arrangement as to varieties, a pair of plants of equal size being placed together, and in the mixture of colour they show well the value of Fuchsias for such a purpose.

Fritillaria acmopetala in fruit.—This Fritillary is a favourite here, where it does well in the sandy peaty soil of one of the borders. It does not appear to be generally known that it is at this season attractive because of its seed-pods. These are of what may be called an elongated pear shape and are each nearly 2 inches in length. The colouring is now pretty, being ivory-white, with green ribs and a green top. The beauty of many plants such as this when in fruit is not always observed, and those fond of their gardens frequently lose much of their interest by removing the seed pods from their flowers when they have gone out of bloom.—S. ARNOTT, *Carselthorn, by Dumfries, N.B.*

Buphthalmum speciosum (syn., *Telekia speciosa*).—As seen in a border among other plants this *Buphthalmum* is not particularly attractive. In such a position it looks coarse. In the wild garden, or, better still, isolated on the grass, one finds it present a different appearance. Planted on grass in good soil and allowed to develop into a large size the showy *Buphthalmum* is very effective, and I was much pleased with it as seen thus in the beautiful and picture-que garden of Mr. J. Rowley Orr at Leddriegreen, in the Blane Valley, Stirlingshire. Of the many plants I have seen this was the finest, its handsome leaves looking well when seen with the grass around.—S. ARNOTT.

Double-flowered Ivy-leaved Pelargonium Achievement.—This was exhibited at the last meeting of the Royal Horticultural Society, and well merited the award of merit which the floral committee gave it. Mr. H. J. Jones, of Lewisham, says the plant is the result of a cross between the well-known Ivy-leaved Pelargonium *Souvenir de Charles Turner* and a pure white zonal Pelargonium. The plants are of sturdy growth, the habit being quite characteristic of a zonal, while the foliage has a pleasing combination of the two parents. The blossoms are large, of a pleasing shade of salmon-pink. This is quite a distinct type of Pelargonium, and is evidently novel and pleasing.—C. A. H.

Escallonia philippiana in Scotland.—Sometimes the preconceived ideas of the tenderness of plants receive a shock on seeing them in apparently rude health where little expected. I was surprised the other day to see *Escallonia philippiana* doing well at the edge of the wood beside the garden of Captain Stewart, of Shambellie, Newabbey, N.B. The shrub was grown as a bush, while even on a wall I should not have expected to see it hardy in this locality. It is very fine on walls in the neighbourhood of Dublin, but some correspondent from the north of England or the east of Scotland would oblige by stating if hardy there. In the south-west of Scotland we can grow many plants which fail in the east.—S. ARNOTT.

Notes from Shropshire.—It may be of interest to know that *Crinodendron Hookeri*, of which mention has been lately made in THE GARDEN, has flowered well this summer in the garden here, as also *Abutilon vitifolium*, both

white and mauve. There is in flower at present a large bush of *Buddleia variabilis* with racemes $1\frac{1}{2}$ feet long, also *Carpenteria californica* and *Fremontia californica*. *Buddleia Colvillei* has stood several winters, but has never flowered. *Magnolia Watsoni* seems quite hardy. *Tropaeolum speciosum* is a troublesome weed here, though the soil is dry and sandy. I believe the best way of establishing it is to plant it in spring when beginning to grow.—T. M. BULKELEY-OWEN, *Telsmore Hall, Oswestry.*

Cytisus scoparius Andreanus in Ireland.—Few plants have made their way into gardens more quickly than Andre's Crimson Broom. It is, indeed, a question if it is not becoming too common, seeing that we have so many beautiful Brooms not nearly enough grown. It is unfortunate, too, that some raisers, anxious to secure and dispose of a large stock, have raised and sent out seedling plants varying more or less from the original and less brilliantly coloured than it. The deep, rich, velvety crimson and gold are wanting in some of these. In going among gardens one meets with many fine specimens, but the finest I have yet seen is in the Daisy Hill Nursery, Newry, where Mr. Smith has a magnificent bush—or tree, as I might well call it—12 feet high and 8 feet through. It has, moreover, the additional beauty of being branched to the ground. In some places a specimen such as this would be considered unprofitable, as taking up too much space, but there can be no two opinions as to the magnificence of such a plant in full bloom, as it was when I saw it. It would be interesting to know if there is a finer specimen in the United Kingdom.—S. ARNOTT.

PUBLIC GARDENS.

Bishop's Park, Fulham.—The Parks and Open Spaces Committee recommended, and it was agreed, that the Council do approve the estimate submitted by the Finance Committee, and do agree to increase by £5000 its promised contribution of £7500 towards the extension and completion of Bishop's Park, Fulham, in accordance with the plans submitted by the Vestry, such further contribution making with the sum of £5000 already paid to the Vestry a contribution of £17,500 towards the entire estimated cost of acquiring and laying out the park, viz., £33,245.

Sparrows.—Can any reader tell me how to get rid of sparrows? Their noisy chirrup disturb me from early morn to dewy eve.—A. R.

Ants.—I am much troubled with ants, destroy *Carnations* by biting off the petals just at the point of junction with the calyx; the ground below is covered with the shed petals. How can I destroy the nests without hurting the plants? Of course, in such a case the ordinary remedies, turpentine, &c., are not admissible. I am putting cotton-wool, loosely pulled out, round the stems, to make, if possible, an impassable barrier. So far it seems a success.—J. R. NEVE, *Camden, Glos.*

Covering a galvanised building.—Could you kindly inform me what would be the best evergreen plants, quick growers, flowering if possible, for me to plant against the walls of a corrugated iron building which I have in my garden? The aspect is south and south-west, but parts of the walls are shaded, part in full sunlight. I am anxious to get the whole building covered as quickly as possible.—B. C.

** We should think the most vigorous of the Ivies would suit you. We should advise you to erect a high trellis round the building and paint it a dark stone colour, or better remove the building out of sight.—Ed.

Names of plants.—*D. M.*—*Poterium alpinum.*—*Henry Boyle.*—The cut-leaved Lime.—*C. L.*—*Ozothamnus rosmarinifolius.*—*J. Ludlow.*—Kindly send flowers.—*A. C. Bartholomew.*—The Flowering Ash (*Fraxinus Ornus*).—*Alice Wilson.*—*Begonia Worthiana.*—*J. Crook.*—Too shrivelled to identify.—*H. S. L.*—*Althaea ficifolia.*

TREES AND SHRUBS.

SOME SHRUB NOTES.

TO THE EDITOR OF THE GARDEN.

SIR,—The number of THE GARDEN for July 30 has come into my hands at this place with other things from England, and I have time for studying it here. There are several things noticed in it which have been of interest to me of late, and I will venture to say a few words about them. I agree with all that "D. T. F." has written about

OZOTHAMNUS ROSMARINIFOLIUS. I must add, from an experience of many years, that this delightful shrub is of very doubtful hardiness indeed. I believe it comes from New Holland, and, like so many other things from that part of the world, when once it gives way at all there is sure to be an end of it. It cannot—at least I have found it to be so—be coaxed back again by any persuasions into vigour and life. I think it must be five-and-twenty years or more since I first came across this very striking plant in the gardens at Glasnevin. Dr. Moore at any rate was alive, and a most pleasant visit still lives in my memory. But of all which I then saw for the first time or otherwise, Ozothamnus rosmarinifolius has even now the foremost place in my mind. I well remember coming across it quite unexpectedly, and I thought I had never seen anything before in the way of shrubs so entirely out of the common; it looked all over as if there had been a deep fall of snow and we had winter in summer. The specimen at Glasnevin was, as I seem to remember, of quite a large size, and no one could have passed along that garden walk on that early summer day without being greatly attracted by it. I wonder if this particular shrub still lives, for if it is alive, Ireland must score largely over the Isle of Wight, for my experience with it has been one of failure and success in strange alternation. Of course it was not very long after the acquaintance I made with it in Ireland before Ozothamnus rosmari-

nifolius was doing well in my garden, and this went on, I think, for several years. I remember its being an object of great attraction at a garden party I had in Ryde twelve or fifteen years ago, and "snow in summer" was the expression which rose from the lips of most persons who passed through my gates. But the glory was only the prelude to a fall, and my shrub, which had become at that time of very good size, was cut off in the winter that followed—and so also was its successor soon after—and for several years I had more or less of difficulty in getting on with it at all. Last summer I fondly hoped that this great favourite of mine was going to put up with me once again, but I was greatly deceived in the idea. It came to grief in the early spring, and soon passed away. I attribute this entirely to a most unlooked-for cause, viz., the severe and unusual drought which prevailed in the Isle of Wight all through last winter. I never should have thought of watering during January and February, but this, I think, ought to have been done in some cases at least, and I have had to pay the penalty for my neglect. I can think of nothing else besides the drought which made last winter so expensive to me in several instances. The rainfall in January last was little less than the rainfall in June. We must learn by experience, though it is sometimes very costly indeed. But as your correspondent "D. T. F." has said, Ozothamnus rosmarinifolius has one very great point in its favour: it is very easily increased by cuttings; and as soon as I perceived in the spring that my shrub was in a moribund condition, I made cuttings of some of the tips of the branches, and I think every one of them struck. When I left home about seven or eight weeks ago they had all been transferred to small pots in the greenhouse, and were doing surprisingly well considering the short time they had been rooted. After a sufficient interval for growth has been passed, I hope to see Ozothamnus rosmarinifolius once more in my borders, but I dare not expect that it will be a very lasting

success. It is difficult to protect it from frost, for I do not think it likes at all to be much covered up, and it would seem also that drought must be guarded against at all seasons of the year.

ROSA GIGANTEA does not move so quickly as "S. W. F." desires. It is, nevertheless, doing well in many gardens in England. Mr. Bartholomew had a specimen of very fair size and which was putting forth strong shoots when I last visited his garden at Reading, and I have one which was kindly given to me at Kew some time ago, and which is fast growing into size, but I am unable to report that it has blossomed. Nevertheless, I have good hope that it will do so. Very often indeed these things need time, and sometimes long time, before they reward us for our pains, but when once they begin to show themselves forth they do not fail us again. The late Major Gaisford was once taking me over his well-furnished garden when we came to a beautiful shrub which was in blossom, and in which he took the greatest delight. Unfortunately, I cannot now recall its name to my mind, and I have nothing here to refer to. He told me a great deal about it, how long he had grown it, &c., and he seemed to think that it spoke volumes for the climate of Worthing that it had done so well, and so I thought too, but it told quite as much for the salubrity of the Isle of Wight and a great deal more for my stupid impatience, for that very shrub I had kept in my garden for several long years until then, and I had only just cut it down and thrown it away because I despaired of its flowering. Perhaps the very next year it might have burst forth in all its glory, and at any rate I learnt a lesson there which I have never forgotten—a good many shrubs and trees must attain to some age before they blossom. Rosa gigantea is safe from all molestation in my hands, and every year that it lives and does nothing I hope will be the last year before its glory commences.

ABUTILON VITIFOLIUM of both colours deserves all the praise that Mr. Arnott has given

it. I have never yet lost it at all, but I have been two or three times informed that it is essentially short-lived, and that young plants should be grown on from seed, so as to take the place of those which will naturally pass away.

CRINOBENDRON HOOKERI, I find, can be propagated with the greatest possible ease. It is esteemed to be very handsome, and it certainly can be grown quite well in the south of England with a slight protection in winter.

MAGNOLIA WATSONI and *M. PARVIFLORA* do well with me against a wall in a very dry spot, though I can quite understand how they would like to have more moisture supplied.

TROPEOLUM SPECIOSUM, according to my experience, exists in a dry place, and now and then it has a blossom or two just to show what would happen if it had things more to its mind; but I very much doubt if in the total absence of wet it is ever seen to great advantage, and if anyone could under such circumstances arrive at a proper conclusion about its extraordinary brightness and profusion of colour. Mr. Arnott should, perhaps, call to mind the fact that Scotland is so often bathed in mist, and I hope I am not maligning it if I say that *Tropeolum speciosum* is generally happy there, because if it misses moisture in one way, viz., in a dry soil, it gets it in another way, viz., from the atmospheric influences which abound in that country. But even in Scotland cultivators tell me that this *Tropeolum* is an essentially moisture-loving plant. Mr. Osgood Mackenzie was the other day so good as to send me from Inverness-shire a large supply of it, and he put a word in his letter to this effect, "Let it have plenty of water," so that although I have grown it for years, and in my ignorance have been more or less satisfied with it, I am in hopes now that quite a new start is being entered on in my garden with regard to this matter. This is not all that I have to say about it, and I came across a very striking discovery only last year. I went to pay a visit to a splendid garden where I saw much and learnt much in several different ways, and, not to mention other things just now, I was electrified at seeing *Tropeolum speciosum* covering a large part of the north front of the mansion and blossoming everywhere. Its vivid red colour, its captivating fruit, and the delightful green of the foliage formed a picture which at an interval of about a year is quite fresh in my mind. If I had supposed up to that time that I could grow *Tropeolum speciosum*, and that I knew what it was like, I came to a very different conclusion upon the spot. Of course I was not long in inquiring about the mystery, and my host was very good in satisfying my desire for information. I felt certain at once that there must be moisture somewhere, and also that there must be something more than moisture to account for the splendid picture before me, and this proved to be the case. *Tropeolum speciosum* revels in a highly-manured soil, and when it gets that, it immediately goes to work to show what it can do; it responds to it at once when it has a good harder to feed upon, and the difference between some highly-fed plants and those that are poverty-stricken can hardly be exaggerated. When my lesson was learnt I determined to act upon it, and in three spots in my garden which are facing the north I had the soil excavated to some depth. The sides and the bottoms were lined with thick clay so as to make them retentive of moisture, and then the borders were filled up with a compost of good fibrous loam and plenty of well-rotted manure, so that richness might be ensured. I left England too soon to gauge the difference in the results but even then *Tropeolum speciosum* was coming

up vigorous and strong, and I have no doubt about its future at all. I am quite of "H. R.'s" opinion about

STRAWBERRY LATEST OF ALL. It certainly is of very great use and of the richest and most exquisite flavour, and it does well in the Isle of Wight.

In thus running through your impression of July 30, I hope I shall not seem to have indulged in the spirit of controversy. With the very slightest exception my letter has rather been in the way of corroborating what has been said by others. *THE GARDEN* of July 30 served to interest me in several ways, and in a place of this sort—delightful though it be—when the last page of "The Last of the Barons" has been nearly turned over—and one cannot read for ever—and when the rain is coming down in sheets, so as to keep one indoors, the "cacoethes scribendi" asserts itself in a rather formidable degree, and you will be the judge whether the results of it lead to anything or not, and whether in horticultural affairs out of the mouth of more counsellors than one wisdom is to be found. HENRY EWBANK.

Adelboden, Canton Berne, Switzerland.

WILLOWS FOR THEIR BEAUTY.

NOTWITHSTANDING the number of trees in the country, we doubt if there is a more picturesque or beautiful one than the Babylonian Willow, which is not common in many districts about London, although it is by the river and in the eastern counties. There are many, however, who plant this who do not care for handsome Willows of erect habit, but, as we think, with more beauty of colour, such as the scarlet-barked or cardinal Willow and the old yellow Willow, now thought to be a variety of the white Willow, and in any case a hardy and beautiful tree. Of late years a number of other Weeping Willows have been propagated in Germany and elsewhere, so that we are no longer confined to the old Weeping Willow, which occasionally was apt to be cut down in hard winters, being, probably, a native of a warmer country than ours. The variety of this Babylonian Willow with the crisp leaf is distinct, but more curious than precious.

SALIX BLANDA.—Among Willows which we have tried, in addition to the Weeping Willow, the most important is *S. blanda*, which we had from Germany. It is a vigorous and fine Weeping Willow, though not yet old enough to show its true habit in our country. It is clearly a fine grower, however, and as it has been tried in the cold parts of Germany, there can be no doubt as to its hardiness.

THE YELLOW WEEPING WILLOW.—Equally important and also of undoubted hardiness is the weeping variety of the old yellow Osier, a common tree throughout the country, and the weeping form of it is likely to be a more important tree than the old Weeping Willow. It grows rapidly with us.

SALIX SALOMONI.—This also, as we have tried it, seems to be a free-growing and most graceful Willow, but, with us, not old enough to show its true form. It is supposed to be a hybrid between the white Willow of Europe and the Babylonian, and is a very rapid-growing tree, as, indeed, most Willows are in river-bank soils.

THE KILMARNOCK WILLOW.—This is a variety of the common Goat Willow, or withy, of our woods, and, like it, is an attractive tree in spring. It is usually grafted, but in this case grafted on its own wild parent, so that the contest between stock and scion, that takes place among grafted Willows, does not occur in it. Half the Willows we have planted have been lost owing to the habit

of grafting curious kinds, wholly different in aspect and habit from the common stock on which they are grafted, generally perishing a year or two after planting.

S. ELEGANTISSIMA.—This is another Willow which has a certain claim to be called a rapid growing, tall, and handsome weeper. Willows have a curious way of crossing and intercrossing, hybridising themselves in all sorts of ways, and it is difficult to account for the origin of this: but from a garden point of view this is not of much consequence.

THE AMERICAN WEEPING WILLOW.—This should really be called the purple Weeping Willow, because it is a European kind, and one of the most graceful. It is not very tall, but has pretty grey slender leaves, with long flexible twigs. It is usually grafted on something else, and grown as a single, umbrella-headed tree, although it is much prettier grouped or massed beside the water. It is only then that one gets an expression of its extreme grace, which makes it as precious as any Bamboo. In our case this Willow was grafted on the common Osier—a very coarse growing Willow of which the shoots spring up for ever from below the graft. If let alone for a year or two they would soon make an end of the purple Willow; but by continually removing them we keep the tree pretty healthy. There would not be much trouble in getting the Willow on its own roots and making it form its own stem. Certain dwarf Willows are also grafted, such as the silvery form of repons; but grafted, as they generally are, on the coarse Willows, their lives are very short.—*Field.*

POPULUS ANGULATA (AIT.) VAR. CORDATA.

How is it that this fine tree is so seldom met with in parks and gardens? Is it because of the false names under which it figures in the nurseryman's catalogue? *P. angulata* var. *cordata* is without doubt a form of *P. angulata*, as see also M. Alfred Wesmael in his interesting monograph on the Poplars. The variety differs from *P. angulata* in the leaf ribs, which are generally green, whilst those of *P. angulata* are red, but especially in its great hardness. *P. angulata*, on the other hand, owing to its susceptibility to hard frosts, especially when young, is in no way suited for cold climates, and is little cultivated for that very reason. Its variety *P. angulata cordata*, on the contrary, will stand the severest cold, and was untouched by the terrible winter of 1879-80. It may therefore be very advantageously substituted for *P. angulata* in countries that are too cold for the latter. In the collection of trees in the establishment of Simon-Louis Frères at Plantières-les-Metz there is a *P. angulata cordata* which is presumed to be about sixty years old. The dimensions of this tree are as follows: Height, about 65 feet; circumference a little above 3 feet from the ground, 6 feet; close to the ground, 9 feet 10 inches. The tree is a female and remarkable for the large quantity of cotton surrounding the seed. I have never observed so much cotton in any other Poplar, and when it falls it is like a carpet of snow on the ground. I cannot recommend too highly this excellent variety, which I consider one of the finest of its race. Like its congeners, *P. angulata cordata* prefers a cool and moist soil. It has produced a sub-variety called *P. angulata cordata robusta*, which Simon-Louis Frères intend to bring out this year. It differs from the parent variety in its extremely quick growth. This sub-variety is the most vigorous of Poplars I know, remarkable, too, for the size of its leaves. It appears to me to be a hybrid between *P. angulata cordata* and *P. Eugènei*, the latter a very quick growing Poplar, presumably a hybrid between *P. monilifera* (Ait.)

and *P. fastigiata* (Desf.), which was raised by Simon-Louis Frères, who possess a specimen of it about sixty-four years old.—M. JOURN, in *Le Jardin*.

NOTES & QUESTIONS.—TREES & SHRUBS.

Syringa macrostachya.—This new Lilac was exhibited at Paris by Messrs. Croux and Fils, of Chateau, on May 12 last, and was awarded a first-class certificate. According to the Journal of the Société Nationale d'Horticulture de France, it is a very distinct variety, remarkable for its large trusses and highly-scented flowers; the flowers large, with ample divisions, flesh-coloured in the early bud, of a bright lilac-rose colour at the time of opening, and afterwards white, very slightly tinged with lilac.

Laurustinus in Cheshire.—There is a very great difference in the growth of the Laurustinus in Yorkshire and Cheshire, so much so that one can scarcely believe it to be the same shrub. In Yorkshire, towards the east coast, the plants only attain a height of something like 4 feet, whereas in Cheshire, in the neighbourhood of Broxton, specimens 12 feet or 14 feet high and as much through are met with. At Bolesworth Castle there are some grand bushes. The soil, formed from the red sandstone rocks of this district, seems to be the medium most favourable to the growth of Laurustinus, for not only do the plants grow to a large size, but the annual shoots are long, strong, and the foliage and flowers of exceptional substance. When in flower in the early months of the year these plants are a mass of white waxy blossoms, and attractive features on the lawn and in the shrubbery. The plants, too, are not only objects of beauty in and out of flower out of doors, as their dark green foliage contrasts with that of the Laurel, Rhododendron, and other subjects of a paler green hue, but the flowers are most useful for house work. Being sweet-scented and possessing lasting qualities in a cut state, the Laurustinus is valuable for indoor decoration, and when the vigour can be got in them like that in these in Cheshire, large branches literally covered with blossom are available. The season of the year that this well-known shrub flowers—February and March—is another item in its favour, for flowers of any kind are not too plentiful then. The Laurustinus being an early-flowering shrub, planters should select a sheltered spot for it—one where the plants will be protected from the north and east winds. Given this and a sandy fertile loam well drained, healthy growth should obtain, and a useful supply of white flowers be secured during February, March, and April.—J. RIDDELL.

A QUIET CORNER.

The Willows are swaying in the soft south wind and the Bamboos yield to the summer breeze, but there is a quiet corner where every leaf is still and every flower at rest. It is a little pool, where the overflow from the larger pond finds exit. Its surface is unruffled, for the water, though moving onward, has a motion so gentle as to be unapparent. Here, in perfect peace, float the white cups of the water Ranunculus glistening in the sunshine.

But what is this ruby light among them? A few stepping stones lead across to the bank on the other side, and here the crimson *Mimulus* has taken root, and, creeping out into the deeper water, mingles with the *Ranunculus*, and lifts erect its succulent stems with gleaming blossoms from the expanse of pure white flowers beneath, its foliage darkly brown, like the shadowed water over which it rests. An *Arum Lily*, too, is nestling by the stones, affording only a stray bloom, but growing freely from year to year with its tall and exquisitely curved leafage. Around the verge, with their rootlets well within reach of the water, the purple *Funkias* are in bloom and the *Iris Kämpferi* send up its spear-like foliage and flower-spikes surmounted by expanded blossoms like huge butter-

flies at rest. Softly bending over this little pool, which we call *Giotto*, because it is so small and round, are the long wands of the Japan Knotweed (*Polygonum sachalinense*). It, too, with its roots in the moisture, has fulfilment of desire and is of commanding growth, and though not yet in flower, its stems have reached some 15 feet in length.

Little wonder if this quiet corner draws us near in the morning sparkle, when the blue sky shows between the silvery Willows, and the swallows with white breast sweep overhead, or in the twilight hour, when the glow of sunset touches the bending branches, and we feel how Nature's calm can bring repose to the human heart. She, too, struggles with adverse storms and cold and drought and needs unsatisfied, and yet, ever fearless, pressing onwards, brings her work to perfection in a summer's eve. A. L. L.

ORCHIDS.

VANDA CÆRULEA.

This lovely *Vanda* is one of those Orchids of which no one ever seems to tire, the handsome blue flowers being so distinct from everything else in cultivation. Whether it can be termed an easily grown plant or not depends upon the conditions under which it is grown, for it is a singular fact that the treatment followed in one place with the greatest success is in another met with failure. Without a doubt many amateur and other growers have failed with it by allowing too much heat and a close, stuffy atmosphere. Because a plant comes from a point very near the Equator, it does not follow that it will need great heat, for high up on the mountain ranges the temperature is often low at night, while on the Khasia Hills, where this plant grows naturally, hoar-frosts are of frequent occurrence. I have both seen and had good results with this *Vanda* in a variety of positions, but the finest plants I ever had were arranged close to a ventilator in a house principally devoted to *Cattleyas*. They grew on the front stage, and as the ventilator was nearly always open, not only light, but air played freely about the foliage and roots. It is no use attempting to grow *V. cærulea* where the house is dark or the atmosphere stuffy. For a time all apparently will be well, the growth luxuriant and green, and flowers produced in fair numbers; but the growth made is not the kind that an experienced grower likes to see. It is soft and easily checked, and is, moreover, exceptionally liable to be attacked by spot and insects. Grown in the position indicated, it is, on the other hand, solid and almost disease-proof; more flowers are produced from it, and a slight mistake in ventilation, watering, or what not is hardly felt by the plants. Yet even given these conditions *V. cærulea* is not always happy, and though for a few seasons after importation the plants grow and flower well, something eventually goes wrong. It may be the roots will die back, turning almost black at the points and failing to obtain proper hold of the compost; spot, again, may set in and weaken the plants, or the centre of the main growth die, and the plant has only backbreaks to depend on. Any or all of these is a check to them, and unless the grower is more than usually fortunate or skilful the probability is that nothing he can do will arrest this backward tendency of the plants. Thus it can scarcely be classed as an easily-grown kind.

The treatment of the roots is not so difficult, for these are fairly vigorous, and soon take hold with a will of anything presented to them.

Large pots or baskets are not required, the roots being always healthier and longer-lived when closely entwined about the basket rods or sides of the pot than when buried deeply in Moss or other material. I have often had fine plants with a couple of good spikes to each in small baskets of about 4 inches wide. I never care to see this species made up into large specimens by placing a lot of plants together in wide pans. Not only do the varieties often differ from each other, but the amount of material that must of necessity be placed about the roots is not at all to their taste. The flat surface of the large pans prevents the grower from syringing the plants, as the water would lie on the surface and render it difficult to determine its real state as regards moisture. This syringing if not too heavily discharged is much enjoyed by the plants, especially on hot summer days, when it rapidly dries off and the water does not run into the leaf axils. It serves to freshen up the atmosphere about the plants and is greatly disliked by insects. The latter are not more than usually troublesome with this *Vanda*, though often imported plants are attacked by cockroaches and the small white scale that affects this class of plant. Ordinary vigilance will keep both these in check, and light fumigations are occasionally required to keep thrips and aphids down. If anyone interested has found this *Vanda* doing badly, it is worth while being at a little trouble to find it a suitable place. Sometimes it thrives in positions that seem the least likely for Orchid cultivation, where the atmosphere may be dry and draughty and where other species would hardly exist. It is wise to try a plant or two in various positions, and when the right one is found to leave them there. Frequent disturbance at the roots is wrong. The roots show their dislike to it by dying off at the points, and this checks the growth. Top-dress the plants annually and cover as many as possible of the roots that have been growing in the atmosphere, and by this means put off disturbance as long as possible. Then do it thoroughly, giving fresh material and cutting away any decayed portion of roots or stem.

H. R.

Cattleya Wallisi.—This beautiful *Cattleya*, though not so large as some of the labiate group, is so chaste as to always command admiration. Flowering, too, when the bulk of the season's blossoms are over, it is more than ever welcome. The sepals and petals are pure white, the lip has a blotch of orange-yellow, and the flowers are each about 5 inches across. In a light open part of the *Cattleya* house, where the temperature as a rule is higher than on the stage, this *Cattleya* does well if planted in small pans or baskets. The roots like a fairly rough and open compost, but not too much of it, as they are not particularly strong. Peat, Moss, and finely-broken crocks or charcoal over good drainage suit it best. Growth commences in late spring or early summer, the plants remaining dormant after the flowers are past. No drying off is necessary, the plants as a rule keeping to their proper season without it.

Odontoglossum Oerstedii.—Very pretty just now are the chaste flowers of this dwarf *Odontoglossum*. They occur on racemes from the base of the pseudo-bulbs, about four on each, and are individually not much over an inch across, pure glistening white, with a yellow centre to the lip. It is a native of Costa Rica, but found at a great elevation, so that the coolest house suits it best all the year round. The plants like an abundant supply of fresh air and ample atmospheric moisture the whole year round, consequently they do well suspended from the roof in company with such as *O. blandum*, *O. Cervantesi* or *O. nevium*. Pans or small baskets may be used and

a compost as usually advised for the genus. The present is not its regular flowering season, but this is by no means constant. When the growths are getting well away, but before they commence rooting, is the best time to give new material to the roots, and the latter must always be kept moist, especially when active growth is going on.

Epidendrum variegatum.—Some of the varieties of this species are so unattractive as to be hardly worth growing, but there are many others that are very pretty and worth a place in any collection. It belongs to the section with fusiform stems or pseudo-bulbs, bearing each a couple or three deep green leaves, from between which the flower-spikes issue. The colour in a plant noted in flower during the week is very singular, the ground of the sepals and petals being milk white, a faint green line marking the centre, while purple-brown blotches occur on each side of this. The lip is a very bright rose in the centre, becoming paler at the margin. The racemes are many-flowered, but all the flowers do not open at one time, and during the evening they are very fragrant. The plants are easily grown in a Cattleya house temperature, and may be placed in fairly large pots of peat fibre and Sphagnum Moss over good drainage. For the strongest plants a little loam fibre may be mixed with this. Plenty of water is needed while growth is active, and a free circulation of air about the plants tends to make them more free flowering. It is a native of Rio de Janeiro and a widely distributed plant that first flowered in this country in 1832.

Dendrobium Phalænopsis.—The lovely blossoms of this Dendrobium are now open, and it is evident that in many places this plant can be well grown year after year, though it must be admitted that in many others its culture is by no means a success. In a neighbouring collection I have noted a few plants with remarkably fine and healthy shoots, notwithstanding they are growing in a house principally devoted to warm house Ferns and stove plants generally. There can be no question that specimens vary in their constitution, some being much hardier and better growers than others, and this is the case with many other kinds rather difficult to manage. A good light, with plenty of atmospheric moisture and ample heat, is necessary while the plants are growing, and after the flowers are past it is all the better for a rest in a cooler house. The plants vary so much in their times of resting and growing that no special seasons can be given, but the most usual resting season is from March to mid-summer, a time when most Orchids are either in active growth or flower. A small basket or pan is preferable to a large receptacle, the roots liking to grow in a tangled mass one over another rather than ramble through a lot of compost. The original *D. Phalænopsis* had whitish flowers with a suffusion of rose, but there is an immense number of varieties now in cultivation, these rendering it one of the most useful of Orchids that bloom during the dead season.

Vanda teres.—There are few more beautiful species than this when the plants are well grown and flowered, the blossoms being bright and telling in the extreme, and much larger than would be expected by an examination of the growth. The ridiculous old system of tying the growths to stakes and allowing them to ramble away with nothing to hold by and the roots in mid-air has become almost obsolete, and a more sensible mode is practised. The stems are grown in proximity to rods or a Tree Fern stem that the roots can lay hold of, or they are cut down and new plants started annually. No Orchid requires a higher temperature, probably, or delights in stronger sunlight than this. In the brisk heated atmosphere caused by well damping and syringing, the sun meanwhile being full on the house, the plants grow like weeds and flower profusely. Plenty of root moisture is, of course, essential, and some cultivators ensure this by planting in a rather deep, but well-drained bed of Sphagnum Moss and charcoal. After flowering

and when the growth is complete, the atmosphere may be allowed to get a little drier and more air be given, so that the plants harden, and by the middle of winter a temperature of about 55° at night is ample. The roots, too, may at this latter season be kept almost dry, the plants thereby being induced to rest thoroughly and starting more freely because of it. *V. teres* is an old plant in collections, having been discovered in Sylhet early in the present century.

NOTES ON PHALÆNOPSIS.

GROWERS of these beautiful Orchids have not had a very pleasant time this season, the long-continued spells of cold, damp weather, when for days the sun never showed through, being anything but suitable for their growth. It is true the temperature may be easily kept up by fire-heat, but the difference in the feeling of a house forced up by this means in dull weather and another kept buoyant and brisk by the action of the sun is very marked. It is important that the leaves of these Orchids are ripened and hardened as they grow. It is as necessary to ripen the growth of a Moth Orchid as it is that of a Vine, but whereas in the case of the latter, growth may be pushed along rapidly at first, and by exposure to sun and air later may be hardened almost artificially, this will not do for the sensitive Orchid foliage. There will be need of great care then during the coming autumn and winter, for, no matter how well the plants may look at present, there is always a danger of soft foliage giving way at the axils in early spring. It is the more puzzling to amateur growers for the simple reason that the effect of ill-considered treatment does not show itself at the time. One may dry the roots of a Phalænopsis for weeks, and yet the foliage will be as fresh as ever and no apparent harm will be done. The mischief is there and will eventually be seen, not perhaps always in the same way, but in some way the evil will out. Drought at the roots is especially harmful now to the semi-deciduous *P. Lowi*. A plant of this species that is in had health at this end of the growing season is very unlikely to stand the effects of a winter's rest, which is really recuperative to strong, healthy plants. A very good way to grow this plant is to tie or wire it to blocks of teak, the latter standing in a pot or basket of crocks and Moss. This being kept moist, the moisture creeps up the block to the roots, while a few of the stronger of these find their way downwards into the Moss. Until signs of rest are observed, then, let these be kept very moist, only avoid wetting the foliage. The longer this remains on, the stronger the plant will be and the better the growth in the ensuing season. The leaves must never be taken off when they appear to be falling; if they keep on all the winter it does not matter, for many plants of this species are nearly evergreen, but it is much better to let them fall naturally than to hasten them when it is plain they are preparing to fall.

During the season of rest, *P. Lowi* requires less water than any other Phalænopsis. If large plants of the stronger-growing members of the genus have the Sphagnum growing very freely about them they will not require very frequent waterings. If too long a time lapses between the time of watering and their drying again, it will be necessary to remove a little of the Moss, in some cases holding more moisture than the roots need. From the present time onward shading must be gradually decreased over these plants. The foliage is much too tender as yet to allow of anything like full exposure to the sun; indeed, more than usual after the dull weather will care be necessary, but the sooner a reduction is made the harder and more robust will the foliage become, and the better able to stand the ordeal of a cold, sunless winter with its lack of light and perforce air. The chink of air on the roof ventilators at night should not be neglected now, a little warmth being kept in the pipes so as to

maintain the temperature of the house at or near 65°. Damp the floors and stages freely with soot-water, this being of great assistance to the plants. H.

Cattleya granulosa.—Among the more recent importations of this old species, some very much larger forms than the original have turned up. I lately saw a flower upwards of 5 inches across, the peculiar greenish tint of the sepals and petals showing rather prettily behind the bright crimson-purple spots upon the lip. It is a medium grower only, but with ordinary care will flower freely. The growth comes away in early spring, the spike appearing from the apex, and after the flowers are past the plant must be kept dormant. Small pots and a thin compost suit it best.—H.

Lælia purpurata.—This fine old Orchid is still (August 6) making a fine show, a large old plant of an exceptionally good type always flowering much later than the rest of the plants here. The flowers are large, the lip exceptionally deeply coloured and handsome, and it is a welcome addition to the list of flowering Orchids now. *L. purpurata*, being a strong-rooting subject, likes more room in the pots than many, and if the growths are well away from the rim of the pots, surfacing is better now than repotting. If possible, keep the plants from growing again after flowering.

Dendrobium d'Albertisi.—The plants belonging to this section of the genus, and including such fine species as *D. taurinum* and *D. stratiotes*, are, it is true, somewhat difficult to manage successfully, and seldom are really good specimens forthcoming. Still, they are very beautiful and distinct, and anyone having plenty of heat at command should try them. It is of little use attempting to keep the plant of the above, for instance, to any set time of growth and rest; the best plan is to encourage it when it begins to grow and to let it take its chance as to the flowering season. The blossoms occur principally at the top of the stems in short racemes, are pure white at the base of the petals and lip, the former tipped with green, the latter having lines of purple. When really healthy it is a vigorous-growing species, but it is not wise to give it too much room, as in case of an overdose of moisture at the roots in winter these are apt to decay. A small pan or pot well filled with roots is more likely to be satisfactory than a larger one with a few roots in the centre of the compost and all the rest without any. Ample heat and atmospheric moisture with free exposure to sun while growing suit it well.

Atmosphere of Orchid houses.—In your issue of the 9th ult. you have an article on the atmosphere of Orchid houses, and among the recommendations is one of placing sulphate of ammonia on the pipes. Would you kindly inform me of the manner in which this should be done, also in what quantity and how often to produce the result desired?—J. G. WOMACK.

* * * If your hot-water pipes are provided with evaporating troughs, these form the best receptacles for the sulphate. It should be broken up roughly and about a tablespoonful placed in each trough, with sufficient water to melt it. Add to the water as it evaporates for about a week or ten days, and then put in a little more sulphate. The ammoniacal fumes rise from this and are most effective when the atmosphere of the house is moist, as it always will be in the growing season. As with feeding plants at the root, so with the atmospheric treatment. Regular and light doses are required, an ammoniated atmosphere being always kept up. If more of the fumes are in the house than the plants can take up it is simply wasted by passing out of the ventilators. There is little danger of overdoing it unless it is gone about in a careless way. The fumes should never be strong enough to be felt by a person entering the house, as these may be injurious to the foliage, especially if the ventilators remained closed while the sun is shining; but if applied as above there is no fear of this.—H. R.

STOVE AND GREENHOUSE.

A BRANCHING DATE PALM.

BRANCHING Date Palms are frequently met with in India. The finest I have seen is the one now figured, and is growing in the Residency garden at Indore, Central India. It is sur-

manure in some form or other. Nitrate of soda, followed by guano, is as good as anything, and the roots should always be moist before applying it. The plants may be cut down when they are done with for the season, kept on the dry side through the winter and started and repotted in spring.

Fuchsia corymbiflora alba. Several of the original species of Fuchsia are very beautiful, and

as in the type, have the exterior of the tube almost pure white, while the reflexed sepals are pink and the corolla bright red. The large white stigma is also very noticeable. A large, sturdily-growing plant of the variety alba is just now flowering freely in No. 4 greenhouse at Kew, in which structure another species is also in bloom. This is *Fuchsia simplicicaulis*, whose loose style of growth fits it for training to a roof, in which position the long pendulous clusters of blossoms are seen to great advantage. In this species the flowers are of a carmine-red tint, and a number of leaf-like bracts interspersed with the blossoms give it a very distinct appearance.—T.

Campanula mirabilis.—One of the most telling of new hardy plants at the meeting of the Royal Horticultural Society on the 26th ult. was this handsome Bellflower. A really good specimen forming a perfect pyramid was shown by Mr. M. Prichard, Christchurch, the plant being well-nigh covered with its pale blue flowers. The example in question was in a 9-inch pot, and to say that the base of the pyramid of blossom was on the average 3 inches in excess of the diameter of the pot all round will but fairly give an idea of the perfect form the pyramid had taken. Lying prostrate on the rim of the pot and spreading therefrom, even the lowest branches were crowded with flowers, and in this way gave some impression of what the plant is likely to be in point of effect when grouped freely in the rock garden. A curious point is the prostrate character of the semi-fleshy leaves that form the rosette prior to flowering, such leaves spreading out to a foot or even more across before attempting to spike. It is obviously a plant that to secure the best results must be grown very quickly from the start, planting out the seedlings quite young before it is possible they can become root-bound. A perplexing question at the present time is whether the newcomer is going to prove perennial or biennial. Present indications suggest the latter, and even at this it can be naught else but an acquisition to good hardy flowering plants. In the plant now referred to the tip of the pyramidal spike arched slightly, thereby producing a singularly happy result. The spike of blossom alone was about 15 inches high.

CYCLAMEN CULTURE.

THERE are few more useful plants than the Persian Cyclamen, and its popularity is well deserved. A few years ago when a good deal of stir was caused by nursery firms showing plants that had been grown from seed in about a year, this culture at the time being by no means general, in certain places the idea that these fine plants were grown in a high temperature gained ground, and even now the older plants are given greater heat than they need. The Cyclamen is a greenhouse plant, and there is no need of stove treatment at any time. All that is needed is a genial, moist temperature with all the light possible in the earlier stages, and shade from bright sunshine later in the season. The best time to sow the seed is undoubtedly as soon as it is ripe. The longer it is exposed to the air the weaker its germinating power. Care is necessary in sowing the seed, the capsules bursting and wasting it if allowed to remain too long on the plant. Sheets of white paper may be laid between the pots, and the seed-pods picked when fully ripe before they burst. Sow thinly with a dibber about half an inch below the surface in pans, using rather coarse silver sand with the compost, and as the seed is sometimes longer in germinating than at others, it may be necessary on occasion to lightly prick over the surface before the seedlings appear. The latter may remain in the seed-pans long enough to get the second leaf only one appearing at first and here the advantage of thin sowing is apparent. A temperature at night of

rounded by Mangoes and other trees. I once saw several of these Dates at a place near Barh, in Bengal.

C. MARIES.

Cassia corymbosa.—This bright and showy old greenhouse plant is at its best now, and standing outside it keeps up a display over a very long season. It is one of the most gross-feeding of greenhouse plants, and consequently when flowering or growing must have liberal applications of

with their varieties are well worth a place in our greenhouses and conservatories, differing as they do in a most marked manner from the innumerable garden forms that we have now in cultivation. The typical *F. corymbiflora*, which was introduced from Peru in 1840, is of quite tree-like habit, with large leaves and immense pendulous clusters of blossoms, which are quite 4 inches long. The variety alba, a very uncommon form, differs from the typical kind only in the colour of its blossoms, which, instead of being rosy scarlet

about 60° is ample at this stage, and the house may be, if possible, kept a little closer when the young seedlings are placed into the small pots. The little bulbs and roots should be lifted out with as little disturbance as possible, and as the former in the early stages rest on the surface, they must be potted just a little lower. At this and subsequent shifts the compost may consist of good fibrous loam three parts to one of peat and leaf-mould, adding to this a little well-dried cow manure and a plentiful sprinkling of coarse sand. At the first potting this cannot, of course, be used in a rough state, but when the larger size is reached the rougher the better. The above is what I use here as compost, but where it is difficult to obtain any of the ingredients, the best at hand must be substituted. Soil, of course, is an important matter, but careful atmospheric treatment is far more so. The best position for the plants all through the spring and summer is on light, open stages in low span-roofed houses, or else on temporary shelves fixed fairly close to the roof glass. In the latter position they are, of course, apt to dry up rapidly and the roots are checked, so examination of the pots twice daily in summer is imperative. The shift into the flowering pots may take place at any time between the middle of July and the end of September, according, of course, as the plants are early or late. I have found that seeds sown in the latter month are fine plants by the end of July and may be potted then. These should commence to flower in November and go on till March at least, and are the most useful batch.

Regarding the resting treatment after the plants have flowered, there is a great difference of opinion among growers. Whichever is the right way, there is no doubt the careless practice of standing them as thick as they can possibly stand in dark pits, frames, or elsewhere is decidedly wrong. No air reaches the leaves, and these naturally soon turn yellow and drop. Some of the plants are very dry, while others are wet, for it is impossible to tell whether they want water or not. In one case they are starved and weakened; in the other the roots are all killed, and the bulbs are sure to start badly. My plan is to remove the light shading provided while the plants are in flower, and water as usual until the foliage shows signs of ripening. Then the water supply is gradually withheld, and the plants have a month or two at midsummer without any water at all. In some cases all the foliage dies off; in others a few of the younger, strong leaves remain, but these as a rule fall as soon as the bulbs commence to grow. Repot when signs of growth appear after a good soaking of water has been given. With these old plants it is safest to leave the top of the bulb just above the compost line. Shake most of the old material from the roots and pot fairly firm. Water as little as possible until the roots have had time to get out into the new material, and keep a moist growing temperature about them. Light syringings are helpful in all stages of the growth of the Cyclamen, but the water must be discharged in a very fine spray and as far as possible applied to the under sides of the leaves rather than the upper. For feeding the plants use weak guano water at frequent intervals alternately with the same quality of clarified soot water, the good effect of the latter being especially apparent in the healthy appearance of the foliage. Should thrips or green-fly appear, fumigate or vaporise the house at once.

Asparagus Sprengeri.—The illustration of this given in THE GARDEN at page 88 shows off this plant well. I have this growing in a pot, and can

strongly recommend it to those who want a plant for hanging baskets. Another way of using it to good effect is to grow it in pots, slightly staking it out with fine stakes. Where there are vases in high positions in rooms, then the plant can be dropped into the vase and allowed to hang over.—DORSET.

Caladium luteum auratum.—It is now about thirty years ago since the late Mr. F. Bause raised several golden-leaved Caladiums that were named after members of our royal family, and which have remained ever since as the best of their class; in fact, very few of this section have been obtained from that time to now. A later addition to this class is *luteum auratum*, which is, I believe, of continental origin. In this the entire leaf is of a uniform yellow with a tinge of green, and though certainly less showy than many other kinds, it affords a very distinct and pleasing variety.—H. P.

ORCHARD AND FRUIT GARDEN.

PLANTING STRAWBERRIES.

In many gardens planting will be late this year, but the delay will not be much felt if we get genial rains, as the soil being warm, root-action will soon be active. Last year I saw a very large quarter of Strawberries nearly barren of fruit. The planting had been well done, the land had been trenched three spades deep, the good top soil placed in the bottom of the trench out of reach of the roots and manures also, with the result the soil that was at the surface was so poor the plants made little progress and were a complete failure. I am aware in some gardens one may trench between 2 feet and 3 feet deep. Much depends upon the soil, but it is not needed if the plants do not occupy the quarter more than two seasons. I adopt a different course altogether, and find it more profitable, having a shallow soil less than a foot in depth in many parts of the garden. I plant yearly and only take one crop from such free-growing varieties as Royal Sovereign, President, Noble, La Grosse Suerée and others of a like nature, keeping the Pine section, Latest of All, and those that may be classed as weak growers two years only. It is useless to plant weak plants in September to fruit next June, and in such a season as this, when runners from fruiting plants will not be ready before the middle or end of August, the plants grown thus will be better the second year than the first. If runners are purchased, I have at times had them too small to make fine fruiting plants the next season. This can be avoided if plants in pots can be purchased for early planting. I grow a goodly number of plants for the production of runners, but there is no loss in so doing, as after the runners are procured the quarter is made tidy and the plants allowed to give a crop of fruit the next year. They bear an enormous crop, and are earlier than those that have fruited before. By planting every year, or at least every other year, the grower who has a poor soil to deal with can obtain much better results at less cost, as the land will be in better condition for other crops. Drought and wire-worm are the greatest enemies I have. To combat these it is useless to place the top spit or old surface soil too far down, and I merely double dig—that is, dig the top spit and then fork up the bottom, the manure being placed between that is under the top spit, and in liberal quantities too. I never use horse manure if possible on such land; cow manure, that from pigs, or both combined are much better, as these retain the moisture, and the plants when they get hold make a fine growth. Night soil mixed with a liberal proportion of soil

is excellent food for digging in; indeed, if mixed with burnt refuse it is one of the best fertilisers for quick-growing crops. I plant as early as runners can be obtained 2 feet between the rows, 18 inches between the plants. This is rather close many will think, but I only take one crop. I tread the land as hard as possible; indeed, it is gone over with a heavy roller previous to planting to enable the plants to make a sturdy growth. Each row of plants is firmly trodden after planting to keep the roots well down. I draw drills previous to planting. This allows of moisture being given freely, and in October the drills are filled in and the plants trodden round. They winter grandly. In growing for runners the trusses are pinched off as soon as they show early in May, and any backward trusses are treated similarly as they show. I have secured some 8000 runners this season. Five thousand are in fruiting pots for forcing; the remainder for planting. I like to have all runners planted by the middle of July, but owing to the late season and drought I am two to three weeks later than usual. By annual planting wireworm is kept in check. I use gas-lime, soot, and charred refuse freely when preparing the land, and it is not lost on other crops which follow, as it checks the spread of club in the Brassica crops and prepares the soil for shallow-rooting crops, such as salads, Spinach, and others. In the following May after planting I give a light dressing of some approved fertiliser. This will strengthen the flower-trusses, and the surface is lightly hoed over before putting on the protecting material. I find fish manure or guano excellent. This, given at the time named in showery weather, is soon carried down to the roots. G. WYTHES.

COLOURING MUSCAT OF ALEXANDRIA GRAPE.

ONE of the many things which try the skill of a Grape grower is the colouring of white Muscats. Some recommend abundance of air, others seem to think a stimulant necessary, while there are not a few other ideas afloat on the subject. Some twenty years ago I had a span-roofed house of Muscat of Alexandria, running at a right angle from a range of lean-to's, in the gardens of Sir Robert Jardine, Bart., at Castlemilk, Dumfriesshire. In this house there was a portion to which no means of ventilation was provided, and yet in this corner I always had beautifully coloured Muscats. A remembrance of this in recent years induced me to adopt a new method in colouring Muscat of Alexandria, and as the results were everything that could be desired, I am penning this note in order that others may try the same, and in the hope that equal success will attend the treatment. Instead of keeping the ventilators open more or less from the time the Muscats showed signs of colouring, I continued to close the house at the usual time in the afternoon, running up the temperature to 90° and 95°. No more air was admitted until next morning, or till the sun raised the temperature above 75°. In short, I continued the treatment suitable to the Vines after the berries were set right on until they were finished. Since I adopted this plan I have not had the least difficulty in securing a beautiful amber colour in Muscat of Alexandria. Of course, such treatment would be detrimental to the colouring of black Grapes; therefore, only such a course as suggested should be adopted where the house is filled with white Muscats, or the Muscats associated with such other white varieties as Mrs. Pearson, Pearson's Golden Queen, &c. Having practised the shutting-up system for colouring Muscat of Alexandria Grape for three years with every success, I would strongly advise everyone who grows this Grape in a house, either by itself or with other white varieties, to give it a trial. Those who do so will

be surprised at the rapid progress the berries will make in colouring and the finish they put on.

J. RIDGELL.

Peach Waterloo.—I gathered this Peach from a south wall on July 26. Few Peaches are superior in colour, and the quality is really good for such an early variety. We have several others equally early. For instance, Early Alexander and Amsden June come in at much the same time. Amsden June was ripe on July 20. I prefer Amsden June and Waterloo to Alexander. The soil may be answerable, but with me Alexander is none too prolific; whereas Waterloo is a grand cropper, and, what is better, the trees usually make a splendid growth. As the variety ripens with Alexander, the two are not needed, and I give Waterloo the preference. All the kinds named are American introductions, but valuable, as they give us fruits so long in advance of our own early kinds.—G. W.

Peach Early Grosse Mignonne forced.—This Peach is not grown under glass so much as it deserves. I am aware it is not so large as the older Grosse Mignonne, but, unlike that variety,

value of Hale's Early, and may not need two varieties to come in at the same time, but this is so distinct and so good that it makes a valuable addition to the Peaches at the season named.—G. WYTHES.

APPLE WARNER'S KING.

Few Apples are so popular as the variety illustrated. Its size and appearance make it well known, and the quality being first-rate there are few gardens of any size in which it is not grown. At the Apple congress held in the Royal Horticultural Society's gardens in 1883 this variety was staged by no less than 110 exhibitors. It had no less than twelve synonyms, favourite names being Nelson's Glory, Poor Man's Friend and the King Apple. This shows its popularity, as it may be grown in most soils and is not particular as to locality. I have seen very fine fruits grown within half a dozen miles of the city and not under the best possible conditions as regards soil and situation. Warner's King may be classed as an

and grass-green skin in an unripe state. When ripe it takes on a clear deep yellow, with patches of brown russet on the sunny side. The tree makes a vigorous growth, and is not much subject to disease. It is one of the best as regards quality, the flesh when cooked being delicious. I find the trees resent hard pruning. The crops from standard trees are grand when the trees are not crowded and the fruits large. As a cordon it bears fairly well, but the hard stopping is not conducive to free fruiting. The greatest difficulty with standard trees is that the fruit, owing to its size and weight, is in rough weather liable to be blown off. To avoid this I would advise a dwarf standard. Avoid crowding the trees, as, to get the rich colour described, free exposure is necessary. It is well named the Poor Man's Friend, as I do not know of any variety more productive or one that commands a better price even when gathered direct from the trees. It is a great favourite on the exhibition table, and always a prominent fruit in collections. In its season it is difficult to beat either for size or quality.

G. WYTHES.

Apple Warner's King. From a photograph sent by Mr. A. W. Brown, Belwood Cottage, Perth.

it forces much better and is a very fine flavoured fruit. Many will think the Grosse Mignonne a shy fruiter when hard forced, but this refers to the older kind, on open walls one of the finest Peaches in cultivation, as it has few equals in quality and is one of the best mid-season kinds grown. The early variety is not quite so large. This ripens with me on an open wall the first week in August in a good season, and the trees fruit grandly. Those who study quality should grow this variety in a cold house. It is one of our best Peaches, not a strong grower, but remarkably prolific. I have frequently had the larger variety sent for the early one. S. M.

Peach Early Canada.—This little-known variety is well worth more attention. It is an American variety, and in that country it is much valued for its cropping. With me it has never failed to crop freely, and, what is better, it can be forced, its season being the same as that of Hale's Early. On open walls I think it is the earlier of the two. The fruits are large, of a beautiful crimson colour, and of excellent quality. The trees make more growth than most of the American varieties, and there is no easting of buds when the trees are forced. Everyone knows the

early cooking Apple, in season from October to early December. I am aware fruits may be kept much longer; indeed, I have seen this variety exhibited in March, but I fail to see the utility of showing fruits when their flavour is gone. With me this fruit is at its best early in October. The soil being light in a measure doubtless hastens maturity. This is one of the heaviest croppers, and it rarely fails to bear freely most seasons. In some soils, if kept, it spots badly. As an early market fruit it always commands a high price if the fruits are carefully packed and graded. Being a soft fruit it soon shows bruises, and in gathering needs more than ordinary care if the fruits are to be stored. It is a great favourite in Scotland, as the illustration will show that splendid fruits are grown in that country. The fruits are very large indeed. Some have exceeded 2 lbs. in weight, but to get size it is necessary to thin freely. My best fruits have been produced on bush trees on the Paradise stock. On this stock it is most fertile, but it makes a good standard in suitable soil. The fruit is well known by its small closed eye

MELONS FOR FRAMES.

PLEASE say what are the best flavoured Melons to grow in ordinary Melon pits without artificial heat.—WESTPORT.

* * In ordinary garden frames I have had Melons equal in quality to hothouse fruits; indeed superior, as the Melon in a frame gets more natural treatment. Houses are often kept in a hot, steamy condition, this affecting the flavour of the fruit. Few varieties will beat the old Golden Gem, but I have found this old variety difficult to obtain true to name. Of newer Melons, Gunton Orange is one of the best for frames. This is a small fruit, but it is of delicious flavour, and, what is so necessary with frame Melons, it is a quick grower, soon arriving at maturity, and has a thin skin. I always find that a Melon that takes long to ripen is not suitable for frame culture. Another point equally important is to grow those of a short-jointed nature and with medium-sized leaves. Varieties with large leaves are difficult to set in frames without artificial heat. Other excellent varieties are Read's Scarlet Flesh, a medium-sized fruit of great merit; Syon House, also a medium fruiter, with a densely netted skin, scarlet flesh, and of fine flavour. The old Beechwood was a grand frame Melon, but it is new not to be had. If another scarlet is needed, Blenheim Orange is a very fine variety. This takes a little longer time to finish than Gunton Orange or Syon House, but it is of first-rate quality. Of white-fleshed varieties The Countess is one of the best, but this needs more time to ripen. Hero of Loeking, not unlike it in size and quality, is a rounder fruit and has a thick skin. This should be grown under the best possible conditions. It does well in a frame with a little heat to finish the fruit, and it keeps longer than many kinds after colouring. Green-fleshed varieties I do not advise for cold frames. These mostly need warmth to perfect their fruit. They do well from May to September, but earlier or later one does not get the best results in a cold frame. Of green-fleshed kinds, Victory of Bath is very good. Of newer kinds, Middlesex Hero, Epicure, and Windsor Castle also do well in frames. For years I grew Melons in cold frames that had grown Potatoes, Beans, or other early vegetables. The soil was levelled over, made firm, and about half a bushel of fresh loamy soil added. In this two plants were put out, one to fill the upper the other the lower part of the frame. The seeds were sown during the third week in April for planting at the middle of May and raised in the frames, as I found I got much sturdier plants grown thus, as they were close to the glass and clean and when planted they went away well. In frames every bit of warmth should be made the most of. At

night the glass should be covered with mats, and in the day it is well to ventilate carefully, not giving a lot of air at one time, but by degrees as the sun gains strength. Early closing is equally important. Plants put out in May will show fruit in the early part of July. The first fruits are secured and the plants are stopped at 2 feet. They then push out laterals, which are stopped at the second joint above the fruit. Artificial fertilisation is necessary, and it is well to secure the first fruits that show, as with frame Melons I would rather have two early fruits than four late ones. After the fruits are set, liquid manure or a good fertiliser may be given freely. Growths not needed may be cut away to admit light and air. As the fruits approach maturity give no food, water sparingly, and admit plenty of air.—G. W. S.

APPLE CULTURE NEAR LONDON.

In dealing with such a subject as this it is, I feel, somewhat of a difficulty to say anything fresh, or what has not by one or another practical grower been already said or written. I shall, therefore, follow lines that have from time to time come under my notice or observation. Let me at once state that I am no believer in what may be called "rule-of-thumb" practice, but, on the other hand, a firm adherent to adapting the circumstances to each respective case. Failures may and do occur, but even in failures we gain experience for the future benefit of ourselves and others. Neither should we be disconcerted if we do not at first, or in after attempts even, always attain the object of our wishes. Perhaps if we always succeeded at the first we should not in the end be any better off, the relaxing of individual effort being under such circumstances the natural sequence. It is a healthy sign for the future fruit industry of this country that the enthusiasm of growers, both amateurs and the trade, is being aroused to producing not only more fruit, but that (what is in my opinion of the utmost importance) of better quality also. What is most needed to bring about this result is a greater regard for detailed or more scientific management rather than haphazard planting regardless of the surroundings, climatic and otherwise, of each particular locality.

VARIETIES.

The Apple amongst fruits is to a great extent what the Potato is in relation to vegetables; it is the staple fruit beyond any question. A good supply of Apples over a prolonged season will well compensate for any additional labour expended in their culture, setting aside, of course, any fancy mode of growing them. I am no advocate for extremely early kinds for private use; for market it may be different. It is an easy matter to obtain the earliest supply from windfalls, besides which the earliest sorts are not oftentimes good keepers. Lord Suffield with me is a case in point. As an early Apple I give the preference to Ecklinville, to succeed which I have had good results from Cox's Pomona. Its one failing with me has been the tendency to split at the stem, after which, if the weather be wet, decay ensues oftentimes. My next Apple on the list is Golden Noble, which in my case has never failed to crop since coming into bearing after planting in 1876; the tree possesses a vigorous constitution, with an erect and sturdy growth. Waltham Abbey Seedling succeeds the foregoing well, being in good condition until nearly Christmas. Then Blenheim Orange comes into use, it being followed by Bismarck, which has quickly established itself as a general favourite. Wellington, which I find to do fairly well, comes next. As a late kind I have had

the best results with Alfriston, and of the newer kinds I give most decided preference to Newton Wonder; it will no doubt supplant the Wellington. An unfortunate name is Newton Wonder, as it may lead to confusion with Newtown Pippin.

Of dessert Apples, I commence at present with Gravenstein, which always crops well and is a sprightly flavoured fruit. Next to it in succession comes King of the Pippins, which is quickly followed by the (in my opinion) prince of dessert Apples, Cox's Orange Pippin, which of itself covers a prolonged season. Scarlet Nonpareil succeeds it admirably. This Apple with me crops well and carries the succession forward into the spring. I have only given a dozen varieties, these being those on which I chiefly rely. Of other cooking Apples, Prince Alfred is undoubtedly a very fine fruit for use after Christmas. Thus far I have not got it into good bearing condition, my trees being young. I have been given to understand that it does best on the Crab stock. Gascoigne's Scarlet also promises well; it is by some growers classed in the same category as the Blenheim, viz., for dessert and cooking. As an October (and possibly later) dessert fruit I favour St. Edmond's Pippin, which belongs to the Russets, and will, I think, prove to be an acquisition, but as yet it seems to be little known. My soil is a light loam resting on gravel which overlies the London clay, and the garden is about 70 feet or 80 feet above the river Thames. During prolonged drought I suffer very much from want of moisture, but on the whole I am able to produce from old trees even good average sized fruits. The one failing is a deficiency in colour. This can easily be accounted for when it is taken into consideration that the garden is only six and a half miles from Charing Cross. I am now gradually forming a new orchard of Apple trees, dwarfs on the English Paradise stock. Thus far I have been very well satisfied with the results, having only commenced four years ago. Last year Newton Wonder and Bismarck of cooking sorts, and Cox's Orange Pippin and Baumann's Red Winter Reinette of dessert fruits gave me some good samples. These and other kinds are planted on grass land (old pasture), the loam being of good consistency, neither heavy nor light, but shallow, the gravel being reached in two spits, or about 18 inches. Here I think the English Paradise will succeed. The one difficulty I have so far found is in the labour of watering, but when the trees are well established this will not give trouble. In planting, I took off the turf and dug the holes some 3 feet in diameter and two spits deep, placing the turf at the bottom, adding to the soil a little light manure. After planting (the distance apart each way being about 12 feet), I mulched with manure on the surface and watered the trees well to settle the soil. I have not thus far dug any more around these trees, nor do I intend to do so at present. My reason for this is to keep in check a too robust growth. If the ground were dug all over and after that again laid down in grass, the roots would ramble away from home, I think, too quickly. By this it will be gathered that I favour a firm soil, which I do for orchard culture. With these trees my intention is to prune moderately. I do not advocate severe pruning in any case; it only tends to a renewed vigour of growth with other attendant evils, as canker. The better plan is to get the trees into bearing as soon as possible, and then adopt the treatment needful in each case. For instance, if there be a tendency to produce strong shoots of a non-fertile character, I would pinch

these shoots so as to encourage the weaker ones, and thus balance the growth. When too much vigour is apparent throughout any given kind, then endeavour to starve the trees rather than feed them, and afterwards use the knife severely. Should I find root-pruning necessary, I shall not hesitate to practise it. This I consider should be done earlier in the season than it is as a rule performed, and that before the leaves fall. It may be thought, perhaps, Why did I not plant standards rather than dwarfs? My answer to this would be from the standpoint of utility. The dwarf trees are more easily managed as regards pruning, the gathering is done more expeditiously, and the fruit is not so liable to injury from winds. Personally I think we have too many standard Apples. Anything beyond 3 feet of clear stem does not find favour with me. When I have perforce of circumstances planted standard trees, I have particularly noted that they have been longer before arriving at a fruit-bearing condition. I have, however, some old trees of standards on grass, planted more than forty years back, which still bear well. The best of these are Waltham Abbey Seedling, King of the Pippins, Blenheim Orange, and Wellington. When at the Deepdene Gardens, Dorking, as foreman, during 1868-70, I noted particularly that the finest flavoured of the dessert Apples were from trees on grass, facing west, the soil a rather light sandy loam. I slightly thin out the old standard trees, removing the cross wood and the weakly shoots as early as possible in the pruning season; this has given better fruits. The unusually wet summer of 1879 was followed by a severe winter. This seriously injured many of the large trees, especially those on cultivated kitchen garden ground. Since then I have gradually lessened their numbers, and still hope to do so, in order to have the cultivated land entirely free of shade for the other crops. It is, I consider, a mistake to encumber the kitchen garden too much with either Apples, Pears, or Plums (or, in fact, any other kind of fruit-bearing tree). It must not be thought that, by planting standard trees, the ground still has the same productive powers as it would otherwise do. It is better to adopt the market-garden system of growing bush fruits and the others of tree-like habit in alternate rows than to take a partial vegetable crop instead. Fruit trees around the borders are very well, being easily managed, but let the quarters be as free as possible. In many cases I am very much disposed to think the non-fruiting character that is evinced by indiscriminate planting where the soil is heavily dressed with nitrogenous manures is thus oftentimes brought about. Then if severe pruning afterwards obtains, the case is only aggravated and canker will ensue. Espalier-trained trees are, I think, preferable in the kitchen garden proper, as the borders will thus be less under shade. Cordons, too, are most commendable for marginal lines. For small gardens, both espaliers and cordons should find more favour, the great point to observe in such limited spaces being that of guarding against any undue amount of shade. To occupy walls with Apples is scarcely advisable when other fruits can be profitably planted against them; should the American blight attack wall trees, the process of cleansing is not such an easy matter.

To plant Apples after Apples on the same ground is a most decided mistake. If it has to be done in order to preserve the uniformity of appearance, remove the soil and substitute fresh. It will pay to do this even if it is only by making an exchange from another plot. Plums or Cherries would be much better if other fruit

trees are planted after either Apples or Pears. It will happen occasionally that some given kind or another does not yield a profitable return. To remove such, root and branch, is not advisable if the tree be healthy and vigorous; the better plan in order to introduce another sort, or to increase those which have been proven to thrive well, is that of grafting. It is surprising how soon a change can thus be made. Either cleft grafting or crown or rind grafting are about the best methods. I have noted particularly that fresh vigour has in some cases been thus imparted to the tree. In selecting trees to be thus operated upon do not commit the mistake of cutting away at the usual period of pruning the branches of such trees, but rather leave them until the time arrives for grafting. The

OLD APPLE ORCHARDS about the country which have been woefully neglected and severely let alone, save to gather the fruit, are oftentimes, and rightly so, condemned. Many of these may yield good crops as regards numbers occasionally, but in size there is a deficiency, and if any are to be sold the prices obtained are not what they should be. I am now thinking more especially of grass orchards. By practising a thinning-out process where the growths are dense, a deal of good may undoubtedly be done in such cases, whilst if the trees are impoverished by bearing crops of small fruit further assistance should be given them in the way of manures; farmyard manure in such instances could be advantageously employed, first removing the turf or digging it in, then mulching the surface, and allowing no grass to grow around these trees for a year or two. Failing farmyard manure, there is the liquid manure, which in many places is allowed to run to waste. Soot or lime would also prove efficacious, but not conjointly, because in a measure one counteracts the other. Road scrapings with either would be a good combination. Of other manures, I would apply bone-meal when and where it can be obtained at a moderate figure. In this way when the trees are free from disease, it will be possible to renovate them to a great extent, exhaustion being the cause of failure. Large orchard trees which bear heavy crops of small fruit are, relatively speaking, more severely taxed than trees which bear weightier crops of finer fruit, but in lesser numbers, the resources of the former being concentrated in a greater degree in the perfecting of the pips or seeds, just the same as in the cases of Peaches and Nectarines, Cherries and Plums, during what we term the stoning period. It is then in every case when the trees are strained to their greatest capacity. Old orchards, which to all intents and purposes are beyond any dealing with in a profitable manner, had better be destroyed and the ground devoted to other crops. Where the trees are apparently suffering from too much moisture in the soil, when such is heavy and retentive, open ditches might be an assistance, or in extreme cases drains would be advisable. In planting a new orchard on such ground I would most certainly advise draining in the first instance. In selecting a

POSITION FOR A NEW ORCHARD, I would prefer the ground to besloping gently towards the south, south-west or west where the loam is heavy or at all retentive of moisture. On the other hand, if the soil be a light or mellow loam, a flat surface would be the better of the two in my opinion. In any case a good depth of loam is preferable. Low-lying positions, where there is danger of injury from spring frosts, should be avoided in all possible cases. Unfortunately, amongst gardeners who have the privilege and

opportunity of planting new orchards, the choice of the position is not left to them so often as it should be. In this, as in other matters pertaining to the garden, it is an egregious blunder to suppose that any spot is good enough either for the garden proper or the orchard. On the other hand, the best possible positions should be accorded, for surely the garden is not or should not be deemed an eyesore. In planting it will pay to do the work well in the first instance, never omitting to water the trees immediately afterwards, whilst care should be taken not to plant too deeply. If the trees be standards, stake them at once, three stakes being better than one thrust between the roots. By pruning moderately the first season, instead of hard pruning, there will be a greater encouragement given to the formation of fruit-buds. Mulching should always follow the planting, it will protect the roots through the winter from too severe a frost, through the spring from parching east winds, and through the summer from extreme drought, and thus lessen the need of watering. It will pay to give attention to this last item of work, and that as closely as possible for the first few seasons. We have to guard as much against the young wood becoming extremely hardened or bark-bound as we have against a too luxurious degree of growth. I strongly advise early planting in every possible case; from the middle to the end of October is infinitely better than any time during November or December. As regards

STOCKS, I favour the English Paradise for all garden trees, except in special cases (as the one I have quoted). To me it seems to be the best in every way for gardens, as it is also for orchards, when due attention can be paid to the trees. In poor soils, the Crab would possibly be the better selection by reason of its greater vigour, as it would too, perhaps, when the after-labour is likely to be too limited. The French form of the Paradise does not appear to be so hardy as the English, and it is not, I think, so much in use as formerly. In one orchard with which I am acquainted, the cooking Apples are worked upon seedlings of good free-growing sorts. The result is all that one could wish, slightly more vigour, perhaps, being apparent than some of us would like to see, yet the produce has been satisfactory. All things considered, I think the English Paradise, by reason of the numerous fibrous roots which it makes, commends itself.

GATHERING THE FRUIT.—Some people gather their Apples sooner than they ought to do for fear of their falling. It would be better if we could leave them as long as possible on the trees. Against this it may be reasonably perhaps urged that the autumnal gales are an uncertain quantity, but I would rather risk the loss of a few than spoil more afterwards through gathering them too early. If some do fall over and above what are at the moment required, they can be turned to excellent account for preserving as jam. For jelly it is better to have all of one kind, but for jam it is of less moment. In gathering, every possible care should be taken not to bruise the fruits. A small gathering basket is better than a large one, and a medium-sized receiver not of great depth is a yet better article. I have occasionally seen Apples that are at all susceptible of impression distinctly bruised when a large quantity has been put into one deep basket. The greater weight, even for handling, is also an argument against this procedure. I daresay most of us have had to contend at some time or another with shrivelling to an undue extent when stored. This will arise from various

reasons. Too much warmth, as when the fruit room is artificially heated, too much ventilation continuously given, and too much woodwork that is neither painted nor varnished are all likely to produce shrivelling. I would rather be inclined to advocate a partially smoken fruit store so as to ensure some degree of moisture. This, too, would keep the fruit safe from frost. A temperature of 36° Fahr. should be the lowest; 40° even is low enough. The best fruit room of which I have had charge was entirely below ground, but the best store place of which I have ever had any experience was a cave which had been excavated for some distance into a sandy bank. Here the fruit used to be kept lying on the sandy bottom; no fruit could possibly have kept better, whilst the flavour of the dessert kinds in that particular case was always noted. It is better to keep the fruit room almost in darkness; this will in a measure prevent shrivelling, all the more so if it be kept nearly closed after the fruit has gone through the sweating process. Woodwork that is not painted or varnished, and brickwork that is not well coated with whitewash, likewise cement floors, are all to a greater or less degree absorbent, extracting the moisture from the atmosphere of the store, and thus in turn the fruit is affected. Too much care cannot be exercised in avoiding the use of hay on which to lay fruit for even a short time, as the pungent properties of the hay will be perceptibly imparted to the Apples or Pears. Anything, in fact, that emits any odour will act prejudicially against the flavour of fruits such as these.

Many of us who are gardeners know that there is a considerable difference in the cooking properties of Apples. There are those which, to use a common term, quickly go to pieces when cooked too quickly or too much, such as the Wellington and Waltham Abbey Seedling, for instance. On the other hand, if these Apples be carefully attended to they are perfection. The properties of good cooking Apples as to their treatment in cooking can be usually discerned during the paring and shing. I fear, however, that with many who have charge of this work, an Apple is an Apple and nothing more. I know some cooks who add water to cooking Apples before cooking them, but this should altogether depend on the firmness or otherwise of the particular kind. In the baking of Apples also there is room for improvement. Oftentimes these are placed in too fierce or quick an oven; the result is that the skins quickly swell up and burst and the fruit is reduced, as it were, to a pulp, the skins themselves frequently being burned brown really before the fruit is actually baked. On the contrary, baked Apples should be placed in a slow oven, or one in which the heat is receding. As baking Apples I much prefer the Russets, the Blenheim or Bess Pool, rather than those with softer flesh. In Apples, however, as in other fruits, there will undoubtedly be a difference of opinion amongst all as to what constitutes the ideal fruit. Perhaps most of us would give the premier position to Cox's Orange Pippin for the dessert. In my opinion it is the best; its medium size is in its favour, so is its firm, crackling flesh, which again stands it in good stead as regards its keeping properties, besides which it is not a rank grower (at least I have not seen it as such), whilst also it is a reliable cropper on the whole. Tastes differ as regards flavour. I think the best flavoured Apple I ever tasted was Egremont Russet; Mannington's Pearmain, too, is one of my favourites. As a cooking Apple, when in season Waltham Abbey Seedling is hard to

beat. I consider it one of the very best, better, to my taste, without any sugar at all (often-times I consider sugar is used too freely). I have alluded to a few of the newer Apples as being tried under my charge. To these I would add Beauty of Bath as an early dessert kind and Early Rivers as another, but for cooking it is earlier than Lord Suffield and has a hardier constitution. Bramley's Seedling is unmistakably an excellent late kitchen Apple, having the essential keeping quality, viz., firm flesh. Although not new, the American Mother is worthy of notice; not the best, perhaps, in appearance, but one of the finest in flavour. Note, however, that it is grown on the Paradise stock. I consider the system adopted by Mr. Crump, gardener to Earl Beauchamp, at Madresfield, an excellent one, viz., that of propagating Apples and other fruits in the home nursery for distribution amongst his lordship's tenants. Mr. Crump is a close observer of suitable varieties for the district, which must considerably enhance the productive capacity of the tenants' orchards. I have scarcely touched on

DISEASES OR INSECT PESTS.—Of the former, canker is the most troublesome, at least from my observation, but, fortunately, I have escaped it fairly well. How to avoid it I have alluded to in previous remarks; to get rid of it is another matter. If the trees be vigorous, allow extension if possible with the hope of better crops to equalise matters; on the other hand, if the trees be, as it were, exhausted, then my advice is to destroy them. Of insects, the American blight is, I consider, the worst enemy. For this, Mr. Wright, of Chiswick, advises Jeyes' fluid, at the rate of half a pint to the gallon of water. I have tried other washes, as McDougall's, which has been effectual. Of the much-dreaded caterpillar in the spring I have had, fortunately, but little experience, I am glad to say; hence I have not made any test for its destruction. At the same time I keep a keen eye in the spring should it appear.

Gunneshury House, Acton. J. HUDSON.

NOTES AND QUESTIONS.—FRUIT.

Melon Hendre Seedling.—This is a finely netted kind, white outside, with scarlet flesh. I consider it an advance on Blenheim Orange. The flesh was tender right to the rind. My fruit was from a plant grown in a big pot on an open stage in a plant stove. It is not an extra large kind. Those who want a fine scarlet-fleshed Melon should give it a trial, as evidently it has a good constitution.—J. CROOK.

Strawberry Royal Sovereign rotting.—On reading over the notes from Mr. Tallack on Strawberries, I observe he finds this kind prone to rot. I agree with him in this, having found the fruits do just the same. Last year I made several rows from plants that had been forced. They made very large leafage and the crop was enormous, but at the beginning of the ripening period a large portion rotted. I should recommend planting this kind wider apart or growing it on somewhat poor, firm ground in shut-in gardens.—J. CROOK, *Fordé Abbey.*

A new Strawberry—Prolific.—At the July meeting of the Royal Horticultural Society several new Strawberries were tested, and a unanimous award given to a new fruit named Prolific. The variety in question is the result of crossing British Queen with Empress of India. The former with me (with many others also) is none too prolific, but immense trusses of fruits and plants also of the new variety were sent to show its free cropping, and it certainly was well named. The quality was so superior, that the committee took it as a standard to test others by, and this is certainly a high commendation. I am aware in some soils Strawberries differ greatly. Some do well, others fail, but those who succeed with this need not trouble about British Queen, which it much resembles, except that it is brighter in colour and ripens to the point, and cropping so freely will be a grand addition to the mid-season kinds.—G. WYTHES.

DESTROYERS.

SLUGS.

In most gardens slugs are very troublesome in spring and early summer, eating up the young seedling plants. In moist localities they are more of a nuisance than where the soil and situation are drier. The kind of soils most favourable to the increase of slugs are also those best adapted by nature for carrying out the methods of cultivation most inimical to slug life, and at the same time aid in increasing the fertility of the land. Loams, and loams inclining to clay, in wet localities almost invariably carry a large number of slugs, and to keep them under should be the aim of the cultivator. The first step in this direction is to have a homogenous arrangement in the garden, in order that a large piece of ground can be dealt with in autumn and early winter. This having been arranged, a trench 2 feet wide and 2 feet deep should be taken out at one end of it immediately the crops are cleared, and the whole vacant space turned over to this depth and ridged. Manuring for the following year's crop can be done as the work proceeds, but except for Carrots, Parsnips, and other deep-rooting root crops, it should not be placed in the bottom of the trench. Rather the top spit should be put in the bottom, then the layer of manure, and on the top of this another spit ridged. By treating the land in this manner all or most of the slugs will be got rid of. Of course there are usually borders to the vegetable quarters, and these are not infrequently filled with fruit trees, bushes, and perennial plants of one kind or another, so that a margin of soil as well as the Box and other edgings form a nucleus in which a few slugs will be able to survive the winter. When the borders contain Carnations, Sweet Williams, &c., it will be found that slugs will make use of them for protection during the winter and spring months. Air-slaked lime is the best antidote for them in such quarters. Pass the lime through a quarter-inch sieve before using it. It will be necessary to lift the growths of Sweet Williams, Carnations, &c., to get at the slugs with the lime. The lime will only kill the slugs at the time it is applied; therefore a good dressing ought to be given to make a fairly clean sweep of the pests. A fair amount of lime should also be dusted into Box edgings when they are small. In spring and early summer, when the crops are being put out, some sifted lime should be kept ready for the first damp night after a period of dry weather and sown broadcast over the land as late in the evening as possible. By taking advantage of an opportunity like this to clear off the slugs, I have had comparatively little trouble with them. In wet times three dressings on consecutive nights will get rid of the majority of the slugs. There are no good results from putting down lime during the day so far as keeping off slugs is concerned, for the moisture in the atmosphere soon combines with it and forms a crust on its surface, over which the slugs pass with impunity. Frequent hoeing checks slugs, closing up the holes in the soil in which they take shelter.—J. RIDDELL.

—Some years ago, says Mr. W. B. Mynors in the *Field*, finding the Strawberries, Lettuces, &c., to be almost uneatable owing to a plague of slugs, I tried various plans, and decided on placing small lengths of old decaying boards, say 5 inches or 6 inches wide and 15 inches to 18 inches long, between the rows of Strawberries and seedlings. Poplar, Alder, Elm or Ash are preferable to Fir woods. In one small patch of a garden, for the first three years, I destroyed an average, roughly counting, of

about 18,000 in a season; now some 300 is the outside, and my Strawberries, &c., are untouched; 100 pieces of wood, after being down three days, after a wet night, produced about sixteen slugs each; a boy, basin in hand, duly collected the 1000 slugs, and with a little fresh soot, lime, or boiling water soon destroyed them. The numbers speedily were reduced, and out of about thirteen sorts of slugs or snails which abounded in this garden only six are now to be found, and in very reduced numbers. An abundance of thrushes has greatly helped in getting rid of our shelled enemies, and I here and there have an unsightly stone, soon well polished, to crack them upon. One day I placed two bits of board on a small bare patch of ground of about 5 yards square; on lifting them I had forty-four slugs, next time twenty-two, then eleven, afterwards one only, nor did any trace of any remain. The spawn of some slugs is to an experienced eye almost as visible as mustard, and, surely, any careful digger can duly account for them. I have also been very successful in reducing beetles, ants, and mice to a minimum.

Getting rid of ants.—C. H. Fernold, of the Massachusetts Experiment Station, recommends the following: Make holes with a crowbar or convenient stick from 6 inches to 1 foot deep and about 15 inches apart over the hill or portion of the lawn infested by the ants, and into each hole pour two or three teaspoonfuls of bisulphide of carbon, stamping the earth into the hole as soon as the liquid is poured into it. The bisulphide of carbon at once vaporises and, permeating the ground, destroys the ants but does not injure the grass. One should remember while using this substance that it is highly inflammable, and no flame, not even a lighted cigar, should be brought near it.

GARDEN FLORA.

PLATE 1183.

THE ALMOND AND ITS VARIETIES.

(PRUNUS AMYGDALUS.)

(WITH A COLOURED PLATE OF P. A. FLORE-FLENO.)*

WITH the exception of the comparatively new Chinese Peach (*Prunus Davidiana*), the Almond is the first of the great *Prunus* tribe to come into flower in early spring. Its earliest flowering variety (*persicoides*) is generally in bloom in the metropolitan district by the beginning of March, and sometimes by the middle of February. From those dates well into April the Almond furnishes one of the most conspicuous and beautiful features of our gardens. It was naturally a tree that would attract the notice of the early travellers in the south of Europe, the Levant, &c., both for the beauty of its flowers and for the value of its fruit, and it does indeed appear to have been one of the earliest introduced of foreign trees. The precise date of its introduction is not known, but it was in cultivation in this country at least 360 years ago. Like the Peach, the Persian Lilac, and other plants that have from time immemorial been cultivated in Oriental countries, the true native country of the Almond was for a long time uncertain, and it seemed to have disappeared in a truly wild state. It has, however, been found undoubtedly wild in the mountains of Algeria during recent years. Like all plants that have been under cultivation for centuries past, the Almond has developed several varieties, although, regarded as a flowering tree, it has not varied to the same extent as many others. It is different, however, where it is cultivated for its fruits. In the south of Europe,

* Drawn for THE GARDEN by H. G. Moon. Lithographed and printed by J. L. Goffart.

for instance, there are dozens of fruiting varieties grown. In its ordinary form the Almond in this country is a round-headed, spreading tree, 20 feet to 30 feet high. Its branches are rather open and its leaves are lanceolate, of a lustrous green, and toothed at the edges. The flowers are each $1\frac{1}{2}$ inches to 2 inches across, of varying shades of rose, occasionally so pale as to be almost white.

In planting the Almond it ought to be remembered that it is leafless at the flowering time. Some situation where there is a background of dark-leaved evergreens ought if possible be given to it. A group which has always struck me as being the most happily placed of any I know consists of some five or six trees planted on a lawn in a sheltered bay formed by Hollies and Evergreen Oaks. Whilst being perfectly hardy, the early-flowering habit of the Almond renders shelter acceptable and natural. It likes a warm soil that is well drained and fairly rich. It is propagated in this country mostly by budding on the Plum stock. Budding appears to be a necessary evil in this case, not only for the perpetuation of named or good varieties, but even for the common one, which is said to be, on its own roots, more particular as to soil and less easy to transplant. Seedlings are, of course, much longer in reaching the flowering state.

The following are the chief named varieties cultivated here for the sake of the flowers:—

PRUNUS AMYGDALUS AMARA (Bitter Almond).—This is one of the finer forms, its flowers being somewhat larger than ordinary, darkest in the centre, almost white towards the tips of the petals. This variety produces the Bitter Almond of commerce, which is used for flavouring confectionery, &c.

P. A. DULCIS.—The flowers of this—the Sweet Almond—do not differ materially from those of the Bitter Almond, although they are usually earlier. The two varieties are so closely allied, that seeds of the one will produce trees of both kinds.

P. A. FLORE-PLENO.—This, which is charmingly portrayed in the coloured plate, is a distinct improvement on the type; the flowers by the doubling of the petals last longer in beauty and are more showy, and at the same time have lost none of their gracefulness. The colour is a deep tender shade of rose. It has been in cultivation at least seventy years.

P. A. MACROCARPA.—This is one of the old varieties of the Almond and is included in Duhamel's list, made early in the century. It is, perhaps, the most vigorous of all the varieties, having larger leaves and flowers than any other. A coloured plate of this variety was issued with THE GARDEN for October 17, 1896, and by that it will be seen that the flowers are over 2 inches across. It is of more erect and less spreading habit than the common Almond. With the exception of the variety persicoides, this is the earliest flowering of the Almonds.

P. A. PERSICOIDES.—We have at Kew two plants of this variety that have for some years past flowered at least a fortnight in advance of the typical Almond. In 1897 they were in bloom early in March, but this year they were fully in flower by February 12. Although little known in gardens, the variety is an old one, the name being included by Duhamel in his list of Almonds. It has been suggested that it may be a hybrid between the Almond and the Peach. The flowers do not differ from those of the common Almond except in their precocity.

P. A. PENDULA is an interesting form with drooping branches.

The older catalogues mention a variety with variegated leaves. I have not yet met with it, and possibly it has disappeared from cultivation. Unless it differs from the majority of variegated Prunuses (which are mostly mere

rubbish), this will have proved no great loss. Besides the varieties mentioned above, which are of interest to us merely as flowering trees, there are, as already stated, many others cultivated in warmer climates for the qualities of the fruit. These are known by colloquial names, and are of no importance in Britain, where the Almond is cultivated for the flowers alone.

W. J. B.

THE WEEK'S WORK.

FRUIT HOUSES.

MELONS.—Those plants which were turned out of pots the first week or so in July have in my ease made the best possible progress. Everything certainly has been in their favour; warm, sunny weather, a steady and genial bottom-heat (from manure and leaves only), combined with a free amount of atmospheric moisture and sufficient warmth in the pipes to prevent any harm or check from a rather low morning temperature (the nights have been occasionally quite chilly) have all worked out thus far good results. Nearly all of the crop is now set, many swelling away freely, these being thinned down to two, three or four to each plant as the vigour of the plants happens to be. Size at this season is all-important for the supply, hence a heavy crop is not so desirable. By maintaining the temperature at an average of 72° at nightfall, I hope to have the earliest ones ripe the first week in September. Preparations are now being made (August 6) for an additional lining of manure on the inner side of the bed, precautions being taken against using rank manure so as to engender steam. Upon this added fermenting material more soil will be placed and a very slight surface-dressing only upon the present roots for fear of raising the bed too high near to the stems. Stopping, tying and fertilising have had to be daily attended to where grown on a large scale. The first is done sparingly always, where possible, by pinching with the thumb and fingers (to let the shoots get large enough for a knife is decidedly bad practice). As the plants have plenty of room to run upwards they are not stopped until a length of 4½ feet has been attained; thus treated there is ample foliage to do its share in the perfect development of the fruits. Tying is done carefully, the shoots being kept on the underside of the trellis so that the wires can do no harm with slack ties. During fertilisation a rather drier temperature is maintained, with extra warmth in the pipes if the weather happens to be dull or damp. As soon as the fruits have attained from one-third to half of their size, the Melon nets will be got out and secured to each fruit, but not any too tightly. These nets are infinitely better than either the old-fashioned roundish tin painted green, the antiquated piece of board with holes, or the cross of raffia. As a precaution against red spider, near to the piping a dusting of sulphur has been puffed lightly upon the lower foliage. When the fruits are well advanced, there will be but little need of either thinning or pinching the shoots. The object should rather be that of retaining the foliage to assist in taking up the moisture from the soil, and then imparting in return quality and flavour to the fruits in their later stages. As soon as indications of colouring appear, be more cautious in regard to watering, but do not withdraw it completely, as some are disposed to recommend. The quality of the soil has, of course, to be considered; if it be heavy and clayey it will, of course, be more retentive of moisture.

LATER CROPS.—To deal with these successfully there must not be any check in the growth now. On the other hand, take advantage of all available warmth by closing early so as to hasten the growth and secure a good set by the first week in September if possible. If the fruits are not well advanced by the beginning of October they have not nearly so good a chance of developing their

flavour. It should be borne in mind that ripe fruits of the best keeping kinds, of which Hero of Lookinge is an admirable example, will keep considerably longer in October than during warm weather in August or the early part of September. The keeping of such fruits is more to be recommended than the forcing of the same to maturity with atmospheric conditions none too favourable.

LATE FIGS.—Late varieties, as Negro Largo, now swelling up their fruits will require every encouragement. Do not be deluded into keeping them too cool, by which means the fruit will never swell up so freely or well, thinking thereby to successfully retard the ripening. If kept too freely ventilated I have found that a semi-ripening process of the wood takes place, which afterwards does not act beneficially in the ripening of the fruit. If, however, the latest batch of pot plants were retarded as long as it was safe to check them in the spring, there will not now be much need of keeping even the latest of these at all on the cool side. Pot plants for late as well as for early forcing are decidedly preferable, being more easily managed in every sense. After the middle of September the second crop in late houses even will be ripe or nearly so. Then the late pot plants will take up the succession, and continue it for some weeks longer. Do not now permit any further extension of wood growth, but stop the shoots so as to force up the embryo Figs on the latest plants. The latest known reliable variety, viz., Nebian, or Grosse Verte, is decidedly later than Negro Largo. It is this I am now alluding to chiefly as regards stopping, but it also refers to late sappy shoots of Negro Largo as well. D'Agén is the latest Fig of all by repute, but so far I have not been able to give it a fair trial. Figs in pots now bearing good crops of fruit will be benefited greatly by occasional doses of weak manure water from the farmyard, whilst as an alternative some tried artificial manure will be beneficial. Take care for the present whilst the fruits are swelling that the plants do not become dry at the roots, but rather keep them well watered. Later on when ripening this treatment will have to be considerably modified. Watch closely for any symptoms of red spider and also of scale and act accordingly; a good remedy for the destruction of these plant pests is to be found in N. L. All insecticide (not vapouriser). For mealy bug it is also efficacious, but in that instance needs to be used somewhat stronger.

EARLY FIGS IN POTS.—By this time this stock should be well advanced towards a thorough ripening of the wood. Some plants may have already cast their leaves, but even if this be the case it must not be taken for granted that the wood is well matured. In every case it will take longer to do this properly. I still have the stock of early pot Figs under glass. Being in a house that is well ventilated, I prefer to keep them there rather than outside just at present. If exposed in the open and not protected at the roots rather more water than is desirable has to be given them, whereas inside this is not the case. Some of the plants will soon have shed their leaves; when this is seen to be general, the plants will be stood in the open. Meanwhile, no sudden check to cause the foliage to fall will be allowed. In a fortnight I hope to have them standing in a warm, sunny position, with a board placed on the most exposed side and wide enough to protect the pots from too much sunshine. Here they will stand until the end of September. In the meantime, if any of the plants really appear to need a shift, it will be given them, but most of this work was done some time back, as then noted. It can, however, be done in the case of St. John and Pingo de Mel with safety when the foliage has fallen (some other kinds will at times cast their first crop if then disturbed at the roots). The real value of these two early forcing Figs does not even yet appear to be fully appreciated in private gardens. In repotting, be careful to guard against too large a shift; one size larger of pot is ample, a steady progress with Figs being much better than a rapid one with a tendency to non-fertility if the wood be too luxuriant. Perhaps, too, we should

hear less about the disease (fungoid) of which we have heard recently if over-exuberance of growth was kept in check with the wood tissues more hardened.

FIGS PLANTED OUT.—Early forced plants of these should now be well advanced towards a ripening of the wood, otherwise they will not be so reliable for early forcing another season. If need be, some fire-heat should still be afforded to trees which have made a free, luxuriant growth, but with abundant ventilation at the same time. Let the leaves fall naturally, it being better to at once thin out super-abundant growth rather than merely strip off the foliage indiscriminately. Continue to syringe once a day or so if any red spider be apparent.

LATE FIGS.—These will be still bearing a crop of fruit, possibly the latest of the first crop in very late houses, but more likely the second crop, the fruits not yet having completed their second swelling stage prior to ripening. In any case it will be advisable to still allow a little warmth in the pipes, provided a fire is not kept alive on purpose; it will be found to add flavour to the fruit as well as being better for the trees themselves. When no fire-heat is given to late Figs planted out at this stage, it certainly should be considered in a month's time, when perhaps it might be done with more convenience. In dealing with houses newly planted, or where the trees have not as yet filled their allotted space, a caution is necessary not to encourage much more growth now, otherwise it will not be ripened by the time the leaves fall. By cautiously keeping the borders a little drier a steady check that will be scarcely perceptible may be given to the trees, yet the object in view will be accomplished all the same in good time. HORTUS.

KITCHEN GARDEN.

MULCHING AND WATERING.—With but little rainfall many of the autumn crops will suffer if not mulched. I have found old spent Mushroom manure excellent for the purpose. Peas and shallow-rooting crops will feel the effects of drought, but a mulch and a thorough watering weekly will keep them going. Runner Beans will fail to pod freely unless given liberal supplies of moisture, as having a lot of foliage it is impossible for light showers to reach the roots. Cauliflowers will fail to make heads if the roots are dry. The plants will be benefited if litter can be laid over the surface soil. I find liberal supplies of liquid manure may then be given, and the plants are much freer of caterpillars treated thus. There will be a difficulty in keeping newly-planted crops going, and whenever possible a thorough watering at night once or twice a week should be given. Beds of seedling Cabbage should not suffer from want of moisture, and if the seeds are not germinating freely it will be well to make a later sowing in case the stock of plants is small. Cardoons will need much moisture, as unless this is given they will bolt badly. Food also in the shape of liquid manure should be given freely.

WINTER ONIONS.—From the 15th to the 20th of this month is a good time to sow the above. By the term winter Onions I mean the Tripoli and Giant Rocca varieties, and though I am aware any of the other kinds may be sown, as they are quite as hardy as the kinds named, they do not turn in so quickly, and Onions in the early summer months are valuable. One of the first to bulb is the Leviathan White Tripoli. This is much earlier than the Rocca section. Early White Naples is an excellent variety, mild in flavour, and fine for autumn sowing. Of course, these types do not keep long, neither are they needed for keeping, as the spring-sown will be harvested for the store. In some soils spring-sown Onions do not do well, and here more attention may be paid to sowing at this date. Plants put out early next spring will not be injured like the smaller seedlings sown in February or March. I prefer sowing these late in August to escape the attack of grub rather than in heat or under

glass some four months later. If the soil has been well manured for a previous crop it will suffice, as what is needed till next March is a sturdy growth. Manures in a liquid state or as surface dressings may be given when growth is active early next spring. Many growers transplant the young seedlings. I transplant a portion, leaving the others, these being the earliest to mature, but they do not attain the size of the bulbs put out in rich soil. I would advise a good space between the rows, this allowing of thinning and cleansing. Thin sowing is necessary, as Onion seed rarely fails to germinate freely. If Onions are grown for salad they may be sown thickly, as they are drawn early, but constant drawing from beds needed to stand the winter loosens the plants, and they do not then stand severe weather. An open position is the best for the Onion quarter, as I find plants well exposed superior to those on a sheltered border. My seed is now being sown on land cleared of summer Spinach. The soil being light, it is merely hoed over and then well trodden or rolled to get a firm hold for the plants. I find I obtain much better results from firm land. I admit the size may be less than one sees in the huge prize Onions, but these are not needed for home supplies.

SPRING-SOWN ONIONS.—These are quite a fortnight later than usual, but it will be well to harvest them before the rains begin, as if the bulbs start into new growth their keeping qualities will be impaired and no amount of care will bring them into condition. I have just gone over the beds and bent down any thick-necked plants that would be long in ripening, and others that are fully matured have been pulled and laid thinly to harden. It is an excellent plan to lay on racks or stages, as this allows any moisture to escape freely, and in damp weather, if room can be found in a cool house, so much the better, as they so soon decay if at all thick and damp. It will be advisable to frequently turn them over, to expose all parts of the bulbs. Later on I find it best to rope those needed to be kept till next spring. If suspended in a cool shed they keep well, and the tying may be done in wet weather. Land which has produced the Onion crop will be in condition for the Cabbage seedlings. This will not need food or digging, merely cleaning the surface. Onions grown for seed, if not given strong supports, will twist and break, as the flower-heads are heavy.

MAIN-CROP CABBAGE.—I have previously advised on the spring crop, and now would give brief advice as to what may be called summer or main-crop Cabbage, as where there is a large demand I find it advantageous to have a late supply. There is no lack of varieties, and such kinds as Mainerop, Imperial, and Favourite are splendid types of summer Cabbage. They are not so large as Enfield Market or Early Offenham, both very fine varieties and great favourites in market gardens, but for a private garden a large Cabbage is not so much needed. Seedlings raised now may be planted out at the end of October or left till February. I plant out a small portion and prick out a goodly number into rows 6 inches apart. They winter well thus, and another planting is obtained in March from the seed-beds. I have in severe winters seen these all destroyed, while those pricked out have been but little injured. It is important to sow thinly if the plants are left in the seed-beds, as if at all close they get drawn and lack roots. Now is a good time to sow Red Cabbage for pickling. Dwarf Blood Red is a small grower and of good quality. The Red Dutch is larger and not so early. In sowing at this season it will be well to have well worked and manured land, as the season of growth is none too long.

COLLEWORTS AND WINTER CABBAGE.—Now is a suitable time to plant out a good breadth of Coleworts for October and November use, and with a mild autumn the supply may be kept going till Christmas. Coleworts to do well need a rich soil, or at least the manure near the surface, as the plant must make its growth in a short time. For the season named I advised the Rosette variety,

and this planted rather closer than Cabbage will well repay for ground occupied. Planting will now be difficult should the heat and drought continue, but it will not be well to delay the work. It may be facilitated by drawing drills, filling these with water previous to planting. For mid-winter supplies—indeed, well into March—I rely upon a good breadth of St. John's Day and the Christmas Drumhead. The former is the earlier. Christmas Drumhead is not injured by the weather, having a dwarf stem and a hard Drumhead-shaped heart. It is a splendid Cabbage for late winter use. These take up less space than ordinary Cabbage, having few outer leaves. They do well planted in an open position in rows 18 inches apart and 15 inches between the plants.

LATE BROCCOLI.—I have just cleared the latest quarter of Strawberries and have planted the same with late Broccoli, having made a sowing late in May specially for late planting. In hot weather it is well to puddle in the plants. I draw rather deep drills and fill these with water before planting. Plants put out now cannot make the growth of those planted a month earlier; on the other hand, these frequently pass through a severe winter when the larger ones are destroyed, and being planted rather deep they have no stem exposed. I do not get such large heads from this late lot, but they are quite large enough for use; indeed, they are appreciated more than large ones. This lot of plants will do well at a distance of 2 feet between the rows and 18 inches between the plants; indeed, if ground is scarce 18 inches each way will suffice.

TOMATOES ON WALLS.—The season of late has been most favourable as regards the ripening of the fruit; but earlier, owing to the cold nights, there was but slow progress, and this caused later flowering. Unless the plants have been kept closely trained to the wall fruit will be late in maturing. All lateral growth must now be kept closely stopped, as from this date the fruits which set will not have time to swell. The grower will do well to hasten the crop that is now set, and to do this it will be necessary to pinch out the points of the leading shoots and to give food freely in the shape of a fertiliser, or, what is better, liquid manure. With gross plants, feeding is not needed. Here more light will be beneficial. I am not in favour of cutting away too much growth at one time. Far better go over the plants weekly and induce a firmer growth. Many growers remove all the leaves, only leaving the bare stems. This is not a good plan, as the fruits often become badly spotted or decay at the centre, and scald also in hot weather. A portion of the leaf may be cut away, but sufficient should be left to cause an equal flow of sap all over the plant. My best outdoor Tomato this year is Conference, both for cropping and quality. S. M.

ROSE GARDEN.

ROSE CULTIVATION UNDER GLASS.

The varieties of the Rose most commonly cultivated in this way are Maréchal Niel and La France, next Niphetos, Lamarque, Gloire de Dijon and some others, but to a much less extent. Souvenir de la Malmaison is cultivated in cold frames, or partially so, being very gently warmed at night, and that only at the time when the most of the buds are half developed, the ventilation by day being thorough and not attended with danger, owing to the climate. Among hybrids the most in vogue are Paul Néron, La Reine, Anna de Vobach, Souvenir de la Reine d'Angleterre, Baronne de Rothschild, &c. In the middle of the house are Carnations, Rose Souvenir de la Malmaison, and even hybrids. The association of dwarf plants in the middle of the house is not, however, to be recommended, because, being too far from the glass and receiving only so much of the light as finds its way through

the spreading branches of the Rose bushes, the flowers are always of second-rate quality. A far better way is to utilise the floor of the house for a plantation of spreading Rose bushes of the same variety as those that occupy the sides, the plants being tied to a low trellis. Rose bushes uncovered during the summer and entirely unwatered, and suffering in consequence from excessive drought, have passed through their normal period of rest for that region. The conditions of climate in fact do not admit of outdoor growth until the end of September, according to the arrival of the first rains (these being absolutely *nil* from May to September) which, outdoors, makes the time of bloom about mid-November. Remunerative culture without glass protection does not aim at producing blooms at this period when Roses are abundant outside, but at delaying the time of flowers until mid-January and to the end of March.

Two means are at the disposal of the grower in securing this result. The first and least effective is to commence watering from the end of September in order to hasten the growth and admit of pruning at the same season, the object being to obtain a first bloom in the months of November and December. The pruning caused by the gathering of the buds causes new flowering shoots, which bloom a second time from January to March, given the aid of moderate artificial heat.

Another method which resembles the preceding, in so far as regards the time of growth and pruning, is to suppress a portion of the flowering shoots when the buds have already made considerable progress, the object being to drive the sap back to the eyes of the base, and thereby delay the blooms. The bad points of these two methods are that they provoke a first bloom at a time when Roses are cheap, and exhaust the bush without profit to the grower and prejudicially to the beauty and abundance of the second bloom, when Roses are scarce, and consequently fetch much higher prices. The second method, which is much preferable to the other, is to prolong the period of repose and delay pruning until about mid-November, watering copiously, with the object of obtaining a single blooming season, but much more abundant from January to March.

In order to prolong the period of rest, special glasshouses of, however, very simple construction are indispensable, the only way to delay the vegetation being to preserve the roots of the bush from all contact with damp. For this purpose the top sashes are lowered before the arrival of the first rains. The glasshouses adjoin, that is, the very narrow spaces between are sheltered by boards covered with zinc and nailed to the abutment posts of each house, thus forming gutters for carrying off the water which comes from the spouts at each end of the glasshouses. This arrangement is absolutely indispensable, for without it the major portion of the Rose roots, being outside the shelter, would be as much exposed to the rainfall as they would if the glasshouses were uncovered, and premature vegetation would be the result, and the object, which is to prolong the period of rest, would be defeated. It is true that in this case the eyes at the summit of the shoot would alone develop, but at the time of pruning the sap would be driven back, which is always prejudicial to good growth and causes the drying up of a certain proportion of the sap, to the detriment of the blooms.

The method above described of arranging the glasshouses is not always followed, and many growers along the Mediterranean coast have made up their minds that the produc-

tion of Roses at a fixed season is materially impossible, basing their opinion upon the characteristic points of the climate of that region. It is a fundamental error, because the failures are solely attributable to defects in the construction of the glass shelters.

The Rose *Souvenir de la Malmaison* is as a rule grown in frames. Treatment the same as that used to delay vegetation is applicable in the cultivation of spreading Rose bushes. Given a very moderate artificial heat and plenty of air, they generally adapt themselves better to two successive blooming periods than those of the other class. It is better not to have more than one season of fine bloom, namely, January to March, than to exhaust the plants by a first bloom in November, when, as I have said, Roses are abundant outside. As yet few growers have devoted themselves to the regular forcing of hybrid kinds, which demand the same conditions of culture as those just described, excepting, of course, the two successive seasons of bloom from the same plants, which is not to be thought of in these sorts of Roses. But in regard to hybrids, the climate of the coast region lends itself admirably to regular forcing, as permitting with equal ease the production of as good blooms at Christmas and New Year's Day as are to be had in northern regions at the end of March, that is, be it well understood, if the time of rest is properly observed.

It is superfluous to add that, whatever the sort of Rose cultivated, copious manuring is indispensable. Farnyard manures largely supplemented with phosphate and lime are generally those which produce the best results, especially in granitic soils, from which these two elements are absent. Rules as regards manuring are difficult to lay down with any good result, as the needs of the plant and the composition of the soil have always to be taken into account.—G. VRAY, in *Le Jardin*.

HYBRID TEA ROSES.

No one twenty years ago would have ventured to predict such a remarkable popularity as the above tribe possesses at the present day, nor have dreamt that the mingling of the Teas and Hybrid Perpetuals would have yielded such a glorious harvest. But the fact remains, and every season brings these beautiful hybrids into greater prominence. It matters little to the lover of garden Roses whether the Hybrid Teas are classed separate at exhibitions or with the H.P.'s. Suffice it that such charming kinds exist. It is commonly admitted that *La France* was the first Hybrid Tea, and it is very remarkable that such a grand Rose should be raised without the aid of artificial hybridisation. That it is a hybrid is, I think, abundantly clear. There is much of the China in this lovely Rose, but M. Guillot was entirely ignorant of its origin. If such a Rose could be obtained by chance, one cannot help thinking that the French raisers, with their glorious climate so well adapted to seedling Roses, have allowed golden opportunities to pass, when they might have obtained by artificial aid many striking novelties that would have equalled, if not surpassed, the accomplished efforts of our own countrymen. It is cheering to know that Mons. Pernet-Ducher is working in this direction, and the results attending his endeavours have been so far entirely satisfactory. The production of such beauties as *Caroline Testout*, *Mme. Abel Chatenay*, *Marquise Litta*, and others go far to prove this statement. *La France* was introduced in 1867, and we had to wait seven years ere *Captain Christy* and *Cheshunt Hybrid* appeared. The former is as popular to-day as it was twenty years ago, but the latter, although a useful Rose, is heavily

handicapped by the dull colour of its expanded blossoms. Another four years elapsed before *Mme. Alexandre Bernaix* appeared. This was a good Rose, if somewhat flat. The next year (1878) witnessed the introduction of Mr. Bennett's seedlings. These were a very disappointing lot, but their introduction was soon to be atoned for by the magnificent varieties that followed from the same source. *Reine Marie Henriette* was also of the same year. The year 1882 gave us one of the best decorative Roses we possess, namely, *Camocens*, also *Lady Mary Fitzwilliam*, a variety that has laid the foundation for so many later novelties. Another Rose of the same year, *Countess of Pembroke*, is not to be despised, and is far superior to many that we have recently seen obtaining gold medals. The next year (1883) gave us *Grace Darling*. It is a charming Rose, so strong in growth, as hardy as a gallica variety, and delightful in colouring, but somehow when cut the beautiful tints quickly fade. The following year we were given *Gloire Lyonnaise*, and in spite of many rivals it remains the best lemon-white variety for garden decoration. *Waltham Climbers No. 1* and *No. 3* followed in 1885. The former is still the brightest crimson climbing Rose, possessing beauty of form and vigorous growth, and the latter a darker shade with lovely recurved petals and deliciously scented. This year also produced the marvellous *Her Majesty*. For the exhibitors it remains a standard variety, but the flowers are generally considered too coarse for garden or room decoration.

Viscountess Folkestone, which I have heard described by some as the most lovely of all Roses, was first seen in 1886. *W. F. Bennett*, one of the sweetest of Roses, and *Mme. Joseph Desbois*, together with the glorious rampant Rose *Olga de Wurtemberg*, were given to the public the same year. *Mme. Germaine Caillot*, which now and then is seen in most beautiful condition, was the outcome of the year 1887, as also was *The Meteor*, which I believe was given away by Mr. Bennett, so little did he value it. A grower in America, however, has a far different opinion of it, for he declared quite recently that all other Roses might go so long as he was allowed to retain *The Meteor* as a crimson forcing variety. *The Puritan* was another Rose of the same year; it had, however, a very short existence; but another variety, *Bardou Job*, is still looked upon as one of the most beautiful of semi-double flowers. *Duchess of Albany* appeared in 1888, and the lapse of ten years has not diminished its popularity. In the forcing house one would take it for a crimson variety, so very intense in colour are its fragrant blossoms. *Comte Henri Rignon* and *Souvenir de Wootton* were introduced this same year. The former is of stumpy growth but highly decorative, being a perfect sheet of bloom when fully out, but the latter is too dull in colour to be considered worth a place, although it is remarkably free. In the year 1889 we had *White Lady*; magnificent in the highest degree are its blossoms, and this season has seen it in wondrous splendour. The white *La France*, a real beauty and so grandly decorative, also *La France de '89*, a fine Rose, which has undoubtedly suffered from its ridiculous name, were also introductions of 1889. The next year (1890) will long be remembered for one of the most beautiful Roses of any year ever sent out. I refer to *Caroline Testout*. I question if any Rose has obtained such unstinted praise as this variety. The raiser, Mons. Pernet-Ducher, gave us the same year the long-budded *Gustave Regis*, and other fine continental varieties were *Marquise de Salisbury* and *Triomphe de Pernet père*. *Pink Rover*, a fragrant pink climber, and *Danmark* must also be included among this same year's productions. The year 1891 was also remarkable, and this time our German neighbours scored heavily with the introduction of *Kaiserin Augusta Victoria*, a variety of equal individuality as *Caroline Testout*. The pretty *Mme. Pernet-Ducher*, the grand decorative *Grand Duc de Luxembourg*, the very distinct *La Fraicheur*, together with lesser lights, such as *Mme. Joseph Bonnaire*, *Baronne G. de*

Noirmont, Progress, and Augustine Halem, were also introduced in 1891. The next year nothing very remarkable appeared. Lady Henry Grosvenor was of this year, but it is a Rose better adapted for indoor than outdoor culture. Marquise Litta was, perhaps, the best of 1893. It certainly is a lovely Rose and of a most pleasing shade of colour. Germaine Trochon will yet make its way, for it is a good grower, with bronzy yellow flowers, and Mme. Jules Finger is a very double white seedling from Lady Mary Fitzwilliam. Hippolyte Barreau, although not very remarkable in colour, has the free-flowering propensity of the tribe, and Princess May is a delightfully fragrant climbing Rose, with the most perfect globular-formed flowers I know, and Mme. Joseph Combet would be grand if its flowers expanded better. I think the palm for real beauties must be awarded to the year 1895. What a grand array! Mrs. W. J. Grant, Mme. Abel Chatenay, Souvenir du President Carnot, Souvenir de Mme. Eugène Verdier, Charlotte Gillemot, Clara Watson, Princess Bonnie, Rosamane Alex Hugier, and Josephine Marot are Roses of the greatest excellence. The following year was not quite so productive, but two first-class novelties appeared, Antoine Rivoire and Beauté Lyonnaise. The former fully sustains the good opinion formed of it upon its introduction. It marks a distinct break in Roses, as it has Camellia-like form, which is very welcome, if only on account of the novelty. Other good kinds of this year were Helena Cambier, Marjorie, Souvenir d'Auguste Mestral, Alice Furon, and Rosette de la Legion d'Honneur, a charming semi-climber, every long shoot flowering at the points and producing the sweetest formed buds imaginable. Of the productions of 1897 I must speak with more reserve, but I have seen sufficient of Madame Cadeau-Ramey and Mme. Jules Grolez to satisfy myself that they have a great future before them. Ferdinand Jamin is good, but does not surpass Mme. A. Chatenay. Ferdinand Batel has a glorious orange shading. Countess of Caledon I cannot say much for; it lacks brightness of colour. Margaret Appert will, I believe, be in much request; so also will Gruss au Teplitz for its very vivid cinnabar-scarlet colour. Ethel Richardson appears a very poor grower, and we certainly do not want any retrogression. Lady Mary Fitzwilliam is bad enough, and I think this matter of growth should be seriously considered before launching upon the world Roses of inferior constitution, be they ever so taking in colour or flower.

Of the novelties of 1898, the gem is certainly Aurora. The grand plants which secured the award of merit at the Temple show were sufficient evidence that this Rose has come to stay. The flowers are very large, beautifully formed, and of exquisite soft pink shade, and in addition to this have a very pronounced fragrance. M. Pernet-Ducher, to whom we turn for good Hybrid Teas, has sent us this year l'Innocence, Mme. Eugene Boullé, and Violoniste Emile Levéque, and as they have all three obtained gold medals in France, they must be varieties of no mean merit. Tennyson is very double and ideal in form, with the fine pointed outer petals of Maréchal Niel. Bessie Brown has been well shown, and altogether I think our home raisers are well to the front. We have room for all these lovely Roses, and if some rich crimsons and maroons are produced, say the colour of Louis van Houtte, with the habit and freedom of flowering of Viscountess Folkestone, they would receive a warm welcome, especially from growers who have other uses for their Roses beyond displaying them at Rose shows. P.

Good garden Roses.—One of the most surprising things in connection with the great Rose family is how really few of the H.P. kinds generally are good garden Roses, that is, creating a show and producing really good-sized blossoms also. Among specially good kinds recently noted Ulrich Brunner is deserving the highest praise, each and every plant of this carrying a full complement of blooms, quite dwarf bushes planted in autumn

bearing a dozen fine flowers, some of which came up to exhibition standard. A good feature among many in this fine Rose is the erect carriage of the blossoms. Equally good in its way is Lady Mary Fitzwilliam, a prettily-shaded flower, very full and pleasing to the last. Another fine kind is Captain Christy, a Rose that rarely fails to produce a good crop of handsome flowers in a soil that is moderately light and warm. In some respects La France is excellent, though the habit is not so uniformly compact as in the kinds previously mentioned. What is especially wanting where Roses are grouped for effect are kinds with good erect habit and short sturdy peduncle. Varieties weak in this respect are wanting in an important point, regardless of size, colour, &c. It is possible an experience on heavier soil would give widely different, though equally serviceable results, and if any reader of THE GARDEN can add a specially good dark Rose which is a success in light or heavy soils and possessing the above points of merit, such will be a welcome addition.

FLOWER GARDEN.

POPPY ANEMONES IN AN IRISH GARDEN.

THE accompanying illustration shows a small portion of an Anemone plot, in size somewhat over a rood, which in the sunshine of an April day

Poppy Anemones in an Irish garden. Engraved for THE GARDEN from a photograph sent by Mrs. Laurensen.

seemed like a rich eastern carpet unfolded and spread forth on the hillside. The plot of ground is on a plateau more than 400 feet above the level of the sea. It is swept by all the winds of heaven, as, standing beside it, one can see the horizon from the time the sun rises behind the distant low-lying hills until it sets in the west, where the young plantations of Fir and other trees scarcely as yet appear to touch the sky. If Anemones like change of air they have it here in perfection, for there is ever a cool current, and frequently a strong blast, passing to and fro between Lough Neagh and the sea. The Poppy Anemones seem to prefer a stiff soil to that which is light and sandy. Moisture in the atmosphere and at the root they delight in, and as they find both without stint in the "North Country," they flourish there with according vigour.

The mode of culture adopted is to take any bit of fresh ground which has been previously cropped with Potatoes and vegetables, and having dug into it a good supply of cow manure, to sow the seed broadcast as early in the month of March as the weather permits, covering with some fine soil in which burnt earth or anything else has been mixed to lighten it and prevent the surface caking. Weeding is carefully attended to, for if the weeds attain any size their removal disturbs the growth of the young seedlings. Indeed, I think this is the main cause of so much failure in the outdoor sowing of Anemones: the weeds attain size so rapidly and the Anemones in their early stage grow so slowly, that when the weeds are pulled up the tender rootlets of the latter are shaken and the soil left so loose, that they perish in the hot sunshine unless water is constantly and freely supplied. The Anemones thus sown and cared for, and thinned out when large enough to handle to 5 inches or 6 inches apart, commence throwing up flower-heads in the month of September, and continue to supply blossoms more or less according to the mildness of the weather all through the winter. As the days of the new year increase in length, so do the blooms increase in abundance until the meridian of their beauty. And thus I saw them last April in their glory, with every petal flung open to the sunshine, while in the distant hilly background the Bracken was still sere and the grass yet brown and scorched from the fierce winds of March. In colour, they varied from the softest pink to crimson and fiery scarlet, and from pale lilac to rich purple and deep blue, with dashes here and there of pure white flowers and those with tips and rings of colour, the blossoms themselves each measuring from 4 inches to 6 inches across.

Now, when August gives us Roses and Lilies, the Anemones are forgotten, but in days to come they will be again precious. A. L. L.

LILIUM SUPERBUM.

THE Swamp Lily is one of the most vigorous of those species (all of which are natives of North America) which have peculiar rhizomatous bulbs. In *L. superbum* this character is especially pronounced, for when thoroughly established this Lily will push out a rhizome to an extent of perhaps 6 inches from the old bulb, and on the point of this rhizome another bulb will be formed, which will in its turn search for new quarters. While the connection between the old bulb and the new is usually totally devoid of scales, it is occasionally studded with small bulbs, which in their turn attain flowering size, till quite a mass or clump is formed. From 4 feet to 6 feet is usually given as the height of this Lily, but good established specimens will sometimes exceed this limit by nearly a yard. The leaves are very sharp-pointed and arranged in regular whorls around the stem, a considerable space generally existing between each whorl. In a vigorous example the elegantly reflexed blooms are mostly arranged in an almost perfect pyramid, and though in shape they vary but little, yet in the colour of the flower and the marking thereof a very great deal of difference occurs amongst them. A particularly deep-coloured form was figured in THE GARDEN, November 29, 1890. In this the flowers were of a bright crimson tint, with a few blackish spots towards the centre. Between this and the lightest-tinted form, represented by a pale yellowish flower, are innumerable gradations of shade and colour, some of the orange tints being particularly effective. The spotting of the flower, too, is just as variable, the size of the spots and the arrangement thereof differing more or less in almost every individual. While in the case of several Lilies we are inundated with varieties, in some of which

the name proves to be the principal distinctive feature, it is strange that varietal names are wanting in the case of the Swamp Lily, though there is a great difference to be found amongst them. This Lily is essentially a moisture-loving plant, but at the same time a swamp is not necessary to its well doing. Some good examples are particularly attractive just now in the beds at the back of the Palm house at Kew.

H. P.

THE CLEMATISES.

SECTION III.—FLORIDEÆ.

(Continued from page 30.)

The *C. florideæ* commence the series of large-flowering Clematis. In 1776 the "large-flowered" Clematis, so-called, made its first appearance. Probably this was only a variety of the Indian *Atragene (florida plena)*. Granted, however, that the introduction of the variety and of the species *florida simplex* took place at the same time, still only the former came to be widely known in horticulture. As we shall see, it was not until half a century later, towards 1836, that *C. bicolor Sieboldi* became known in European gardens. Like the *azureæ*, the *florideæ* came to us from Japan, not Florida, as I have seen it stated in certain catalogues. They are allied to the *azureæ*, but there is a notable difference in the flowers, in the time of bloom, which is a little later, and especially in the evergreen foliage of the *florideæ*. There is a difference also in the leaf, which, instead of being simply three-lobed, is entire and hairy. The *florideæ* are delicate plants and have long been classed as greenhouse Clematises. They can, however, be grown in the open air in favourable situations, with light soil rich in vegetable mould. In ordinary winters in a temperate climate they retain their foliage. The following are three well-established forms under which the Japanese species group themselves:—

C. FLORIDA (Thunb.).—The single-flowered Clematis *florida* I have had some time in cultivation; it is seldom found in catalogues. This typical species is remarkable for its single milk-white flowers, which are of fair size and flat. I have never seen *C. florida simplex* in collections of the present day.

C. FLORIDA PLENA (Wild.), *Atragene indica (Desf.)*, *Atragene florida (Pers.)*.—The Indian *Atragene* of horticulture is still frequently met with. It is a summer-flowering plant, and the flowers, which are double, greenish white, last a considerable time. This variety is constant, but more curious than beautiful.

C. BICOLOR (Cels), *C. florida Sieboldi (Hort. Belg.)*.—The bi-coloured Clematis of Siebold, as it is often called, is a very distinct and interesting variety if we consider it as not belonging to the species. Its first introduction was in 1829, along with *C. azurea*, to the Botanic Garden at Ghent, but until 1836-38 it was not much known in French gardens. In foliage and habit *C. bicolor* resembles the foregoing species, the essential difference being in the flower, which is double and bi-coloured. Encircled by a white collaret of large sepals, the centre forms a corona of little violet petals, which impart to the flower a certain resemblance to the *Granadilla* or *Passion Flower*. These petals are stamens in process of transformation into brown-coloured exterior anthers; the interior ones continue with the pistils after the fall of the bloom.

The *C. florideæ* give a long and continuous bloom during the summer owing to the growth and the development of the branches. They may be pruned, but it will retard the bloom. In mild winters, when they retain their leaves, they start into growth early. Among the section of *florideæ* I place a charming and constant hybrid known for more than thirty years—

C. FLORIDA VENOSA (Viticella venosa, Hort.).—Its parentage is revealed by all the characteristics of the hybrid; the same carriage, divided foliage, flowers of like form, having five to six petals of a fine violet-blue with rosy, velvety, and iridescent tones. Hardly and prolific in bloom, *C. florida venosa*, after being long with me in cultivation, accidentally gave perfectly mature seed, which, sown in 1879, sprang up and gave birth to diverse products, of which I shall speak in treating of the hybrids. DR. JULES DE BELLE, in *Bulletin d'Horticulture de la Sarthe*.

(To be continued.)

A DORSETSHIRE STREAM-GARDEN.

HAPPENING to be on a visit in Dorsetshire during the early days of June, I was taken by my host to Minterne Abbey, where, by the courtesy of Lord Digby, I was enabled to inspect the charming stream-garden which has during recent years been formed in the grounds. Minterne Abbey itself, though distant but some fifteen miles from the sea, stands at an elevation of 600 feet above sea-level, while from the hill of High Stoy, scarcely more than a mile away, a panorama is unfolded that can be rivalled in few counties of England. Mile upon mile stretch the pleasant pastures, fertile and well wooded, until the light green of the grass is lost to view and the darker tint of the foliage of the trees alone is visible; this, again, under the spell of the intervening atmosphere, changes colour as it recedes from the eye and blue distances melt imperceptibly into the still bluer remoteness where, afar, the furthest hill-top cuts the clear sky-line. Approaching the house, a steep grass slope on the left falls into a deep valley, where shimmer the waters of a lakelet, dark by contrast to the snowy plumage of the swans that float on its still surface. On the further side the ground again rises rapidly, the silver-grey and fawn of the Jersey cattle intensifying the bright green tint of the grass, while the summit of the slope is fringed with noble trees. The walk to the stream-garden descends gradually between fine Beeches, the open spaces planted with *Azaleas* and *Rhododendrons*, interspersed with Lilies, while in the grass *Narcissi* are naturalised, and in the shadier spots Ferns flourish in profusion. Before the region of streamlets that intersect the lower level is reached, three lately-constructed rock gardens, enjoying varied positions of sunshine and partial shade, are passed, in which among the plants in bloom at the time of my visit were *Aubrietias* in variety, *Geums*, *Gypsophila cerastoides*, *Lithospermum prostratum*, and a number of *Saxifrages*, of which *S. lingulata cochlearis*, *S. nepalensis*, *S. Macnabiana*, and *S. valdensis* were conspicuous. Into the stream-garden, which not many years since was an Osier bed, many sparkling springs well out from where the abruptly sloping hills meet the gentler contours of the lower lands; one, rising beneath a Holly tree in a shady dell, whose steep sides are veiled with Fern fronds, spreads itself into a crystal-clear pool, whence, rippling with musical murmur into the sunlight, it meanders down among the flowers and foliage of the delightful wild garden that fringes its banks through many a curve. In this retreat the Lilies are evidently at home. The tall, slender shafts of *Lilium auratum*, on which the buds are not yet apparent, look the picture of health, while the sturdy flower-stems of the giant Lilies of the Himalayas promise many a coronal of vanilla-scented blossoms poised at a height that no other Lily may attain. Tall Mulleins with grey-green foliage are in flower, as are a host of Poppies, whilst the delicate

tints of the hybrid *Aquilegias* produce an exquisite colour-effect in their green setting, and *Irises*, *Ixias*, and the greater *St. Bruno's Lily* are blossoming. In one spot masses of *London Pride* and breadths of blue *Forget-me-not* create a charming picture, while here a colony of *Solomon's Seal* bends arching, flower-studded stems above the rivulet, over whose margin the crimson and gold of the *Mimulus* have in places encroached. Here the Japanese *Primulas*, rose-coloured and white, show, by their vigour and the abundance of their blossoms, their appreciation of the conditions by which they are surrounded. In the background a yellow *Day Lily* gleams against the crimson foliage of a *Maple*, and graceful form is expressed by slender *Reed* and grass or tapering *Bamboo*. Of these latter a walk was planted some four years ago, and the bright green foliage of the arching shafts evidences that their vitality has been unimpaired by the past winter, whilst the strong young growths, almost 5 inches in circumference, promise to exceed the stature of the mature canes by many feet. *Bambusa Simoni* has already attained a height of 15 feet, and between its swaying stems a suspended nest shows where the black-cap has reared its brood.

Flowering shrubs and trees are well represented in the stream-garden. There the *Laburnums* spread their showers of gold, *Lilacs* perfume the air, and *Azaleas* glow in scarlet, orange and yellow. The *Snowdrop Tree (Halesia)* produces its white bells and *Viburnum plicatum* its snowy bloom-trusses; *Weigelas*, *Staphyleas*, *Lycesterias* and *Pernettyas* flower; and as midsummer approaches, the *Syringas (Philadelphus)* are odorous with blossom, and the *Austrian Briers*, yellow and copper, with the *Japanese Roses (R. rugosa)*, both single and double, are in full bloom, while later the *Spiræas* in variety perfect their feathery inflorescence. The *Plantain Lilies*, with their handsome cordate leaves, provide fine form in their bold outlines, the blue-green foliage of *Funkia Sieboldi* being especially admirable in tint, and for richly-coloured leafage there are *Prunus Pissardi* and *Acers* of varied hues, one brown-red *Japanese Maple* having a spread of 10 feet.

Crossing the stream by stepping-stones hard by where a tributary spring joins the main current, one sees the limpid water sparkling round a bend, shadowed here and there by giant over-arching Fern fronds. Further down its course tall trees interpose their leafy tracery between stream and sky, permitting only a stray sun-shaft to flick the ever-rippling surface of the running water, that anon reaches a barrier through which it forces its way, and, emerging from a bank of Ferns, falls foaming over rock and boulder to a lower level. In this sanctuary the peaceful monotone of the falling water, that "sound of loud repose," is ever present, varying but little with the circling months, for the volume of the springs is constant, and is but little influenced by the periods of torrential rains and drought that render many a rivulet now a foaming rush of turbid water, now a reluctant trickle that scarce has power to thread the flag-leaves that fringe its course. The seasons come and go, but the voice of the cascade, heedless of the passage of time, remains unchanged, and as its unvarying cadence falls upon the ear, the words of the gracious motto that encircles the sundial on the neighbouring church involuntarily project themselves on the retina of the mind. "Le temps passe, l'amitié reste." The tender sentiment is a reminder that other and more precious things than the song of the fall are

unaffected by the lapse of years. Of such are the

Friendships folded, put away,
Pressed into memory's leaves like faded flowers.

Time passes, but remembrance remains unaltered.

Thoughts and remembrances: these are the things that remain for ever.

But, despite the languorous refrain of the fall that has for a while rendered the listener oblivious of the prosaic side of life, the stream runs on its course unresting, and, waking from the reverie, one follows where Osmundas lift their plumed frondage on the verge of banks carpeted with the fresh green of the Oak Fern, where the American Maiden-hair (*Adiantum pedatum*) and other exotic Ferns have found a congenial home, while here and there *Lithospermum* and *Oxalis* peep out among the fronds, the Lily of the Valley grows in masses, and, earlier in the year, the *Cyclamens* brighten spaces with their reflexed blossoms. Trees of all descriptions flourish in the iron and potash provided by the green-sand formation, fine Cedars, Larches and *Illex* evidencing by their luxuriant growth that the soil is to their liking, while a giant *Taxodium* rears its lofty column in sight of the abbey, and deciduous trees, such as Beeches, Oaks and Limes, have reached stately proportions. S. W. F.

Campanula celtidifolia var. cœlestis.—The note by "D." in THE GARDEN of 30th ult. (page 78) is a timely one, and may, one hopes, draw the attention of some to a beautiful, but comparatively little known, member of this beautiful genus. *C. celtidifolia* is a very free bloomer, and does well in the ordinary border. In going through Mrs. Maxwell-Witham's garden at Kirkconnel, Newabbey, N.B., the other day, I again saw the variety grown there as *C. c. var. cœlestis*. The name under which it was received from the nurseryman who supplied it is not a very happy one, as there is nothing about the colouring which can be considered in keeping with the varietal title. The flowers may more aptly be called reddish purple. Purple flowers are not favourites with many, yet this bellflower is free from the tints usually considered so objectionable. *C. celtidifolia cœlestis* has been grown at Kirkconnel for several years, but in no former season have I seen it more attractive.—S. ARNOTT.

Fuchsia Scarcity.—In Hyde Park one of the features is the number of large Fuchsias that are employed, and though several varieties have at one time or other been used, the selected ones are but few in number. Of dark kinds, the variety Scarcity is met with almost to the exclusion of all others, it being in every respect well adapted for such a purpose. It is of good free, yet sturdy growth, pushing forth its side branches horizontally or nearly so, while it is exceedingly free flowering. The blooms are large, the single corolla being of a rich plum colour, while the sepals, which are partially reflexed and thick in texture, are red. Taken altogether, it is one of the very best varieties for such a purpose. Another somewhat in the same way, but not used to anything like the same extent, is Tower of London, which is of a rather more drooping habit. Of light kinds, the old market variety Mrs. Marshall still holds its own, and the equally old Mme. Cornelissen is the principal representative of those with white corollas. That very distinct form Earl of Beaconsfield is also very effective in the open ground.—H. P.

New Tufted Pansies.—As to these it is not easy to gauge the public taste. The large bedding Pansy with a sprawling growth seems to please some of the growers, if one may judge by the prize-lists at the National show. My efforts have been in the opposite direction, and with a

profusion of moderate-sized flowers and a flat profliferous growth as to habit. I think now I have many varieties with the habit of Blue Gown, white, yellow and blue. Although yellow Tufted Pansy Rowberry has a sprawling habit, the colour of the flower and quality of petal are not excelled. With pollen from that variety I have crossed Gold Crest and Coolgardie, two of my dwarfs, with distinct results. The seedlings from that cross are great improvements. I have several bedding varieties with the right habit, golden flowers, and a profusion of them. These will, when known, be grown by all who want a nice contrast in colour. These do best in a light soil of leaf-mould with rotted manure, sand and light loam. The season in the north has been windy, over-dry, and no great growth on anything. We may come to have a fine autumn, however.—CHARLES STUART, *Hillside, Chirnside.*

ANDROSACE SARMENTOSA.

This beautiful spring-blooming alpine is a native of the rocky pastures of the Himalayas. Its flowers are of a lilac-pink colour, in handsome umbels, and it blooms for four or five weeks from the middle of April. Like many other

Androsace sarmentosa. Engraved for THE GARDEN from a photograph sent by Mr. J. Soltan-Symons, Chaldalewood, Plympton.

woolly-leaved alpines, it suffers much from damp, and consequently should be planted in a slanting position and protected with glass in the winter. When not in bloom its broad rosettes of leaves always make it pleasing and attractive for a rock garden. The engraving is from a photograph taken towards the end of last April. It was planted ten years ago, and now covers a space of 4 feet by 3 feet. The soil it is growing in is loam, peat, and leaf-mould in equal parts, and it is fully exposed to the sun. It is watered freely during the summer, and covered during the winter months with a light form of garden frame. G. H.

Lilium Browni.—This Lily, noted on p. 81, will occasionally produce three flowers on a stem, but at the same time two are of far more frequent occurrence, while one large solitary bloom is very common. Some bulbs of this Lily that I planted quite early last year have behaved in a very erratic manner. They showed no signs of growth above ground during the whole of last season, though the bulbs were found to be perfectly sound, with many roots in good condition. They were then allowed to remain undisturbed, and

this season four of them have borne three flowers each, while there are several with two blooms. It is certainly in every way a very beautiful Lily, while it is also more robust in constitution than some other species.—T.

Carnations.—This has been a bad season for border Carnations in this district, and very few really good flowers have been seen. The plants came through the winter better than usual, but most of the flowers are thin, poor, and very badly infested with thrips, which seem more than ordinarily plentiful on all crops that they thrive on this year. The varieties that have done best are the old Raby Pink, Marguerite Hamel, Burn Pink, Alice Ayres, May Queen, Carolus Duran, Salamander, and a few selected seedlings. Those which are not seen to advantage include Murillo, Hayes' Scarlet, Ellen Terry, Gloire de Nancy, Miss Audrey Campbell, King Arthur, and Uriah Pike. For the first time for many years I have a perfectly healthy stock of Mrs. Reynolds-Hole. This came to me last year to replace the diseased stock that I discarded, and this it has done well.—J. C. T.

Double-flowered Martagon Lily.—It afforded me great pleasure to learn that this rare variety of the Martagon Lily was in such a thriving state at Kerkeonnel, for it is now-a-days very seldom met with, and even if seen, by no means invariably in a flourishing condition. The most vigorous of all the Martagons appears to be the variety dalmaticum, many grand examples of which have come under my notice this season. Unfortunately, all the bulbs disposed of as dalmaticum are not of equal merit, the true variety having flowers of a solid blackish purple tint, whereas in others the colour is more or less washy. Concerning the bulbs of the Martagon Lily, it may be pointed out that the scales are so brittle, especially just at the base, that they suffer from rough handling more than those of almost any other Lily; hence in transplanting them they should be handled with especial care, and the large stout roots at the base of the bulb should be damaged as little as possible. With all the care that may be taken the bulbs will sometimes be dormant or nearly so for a season after transplanting.—H. P.

TUFTED PANSIES.

WITH plenty of rain, cool nights and dull days these are having a grand season, and some few which have given trouble in former years to get stock of are promising to produce plenty of cuttings of the right sort this year. Of the latter, Holy-rod is the worst I grow, but the colour is so rich that it cannot be discarded. Quaker Maid has a fine constitution and gives no trouble, but during the past year or two the flowers have run to such an extent as to destroy the soft quiet shade of colour it once gave. A few plants remain true, but the flowers of the rest are flaked and striped with purple. Propagation from unaffected plants only does not stop the progress of rogues, neither does autumn planting. I should be glad of a hint to help, as flowers of the true type are valued. Countess of Kintore is one of the showiest and most constant, the only thing against it being its straggling habit, but this is almost necessary to such a constant flowering variety. The Mearns is another favourite that has taken to running, but as in this case a self-coloured rosy purple flower results in place of the bi-coloured type, no harm is done. Souvenir, one of the very earliest, has the biggest flower of any variety I grow: it is wonderfully free and bright and makes a handsome group. The strong growth made looks, when out of flower, like fat Water-cresses. After a fortnight's rest this is now beginning to produce a second and heavy crop of flowers. Bullion is a fine, free and bright yellow variety that hardly ever slackens flowering during the spring and summer months, but it has not supplanted a much older and equally free yellow named Golden Bedder, a particularly dwarf variety of the Pansy type as to flowers, which have a "face" in them, but close and tufted as

to growth. *Sylvia* is a very free creamy white of good habit. *Violetta I* do not care for, it is so late in beginning to bloom; still, it is pretty, and a freer type with the same sized flower would be very acceptable in many colours. A few excellent home-raised varieties with the right habit and constitution and in various colours make up, with the ever-flowering little *Viola cornuta*, the set grown here after many have been discarded. The last mentioned rarely forms any seed-pods here; consequently there is no check to its constancy in flowering, and I look on it as quite an excellent plant. J. C. TALLACK.

NOTES AND QUESTIONS.—FLOWER.

A white Thistle.—Do any of your readers know of a white Thistle or a white-flowered variety of one?—V. B.

Saxifraga Burseriana.—In the notes on Saxifrages at page 79 there is a slight error by the omission of two words, which gives a giant size to the rosettes of the above species. In the passage commencing "Once or twice lately," page 79, half way down, read "wherein patches of rose tes," &c.—E. J.

Campanula pumila alba.—Quite recently I saw this growing in a wide band at the edge of a low wall in a cottage garden near to where I reside. It was in full bloom. This is the way to see what these plants are capable of doing. Cottagers about here take much pleasure in growing many of the showy hardy plants, and they grow them well.—J. CROOK, *Forde Abbeu.*

Acartholimon venustum.—I have successfully increased this plant in this way: Make a small hole in the ground, into which press a portion of the stem; on this put a handful or two of earth, and a stone on the top to keep it all in position—in fact, exactly in the way Carnations are layered, but without slitting the stem. Roots are emitted from the buried portion, which can be cut away from the parent plant in the spring.—J. R. NEVE, *Camden, Glos.*

SOCIETIES AND EXHIBITIONS.

MIDLAND CARNATION AND PICOTEE EXHIBITION.

AUGUST 5 AND 6.

This exhibition of Carnations and Picotees was one of the finest we have seen anywhere, and we are pleased to find that the midland growers can promote such a keen competition in almost every class as we saw on Friday last. The show was held in the Botanic Gardens at Edgbaston, and the flowers remained fresh surprisingly well. Unfortunately, on the second day a heavy down-pour of rain continued throughout the afternoon, and must have kept many hundreds of visitors from seeing a very fine display of flowers. We shall not attempt a detailed report of the show, as a prize list is given in our advertisement columns. This will show that the southern growers, especially Mr. Martin Smith (gardener, Mr. Blick), came in great force, and the last-mentioned exhibitor succeeded in winning many of the chief prizes, including the challenge cup, given to the exhibitor who wins the largest number of prizes in certain classes. But we are pleased to know that a Birmingham amateur grower, Mr. Cartwright, of Selly Park, Edgbaston, was a very few points behind—a creditable performance, indeed, in face of the very strong competition. The challenge cup, open only to the trade, was won by Messrs. Thomson and Co., Sparkhill, Birmingham. Mr. Robert Sydenham, who has done so much to foster the cultivation of the Carnation in the midlands, and to whose energy the vigour of this society is in no small measure due, did not compete this year for the cup, having won it at the show last season.

This has been a remarkable year for the Carnation, and last week was quite early enough for the midland competitors, when such southern growers as Mr. Martin Smith, Mr. James Douglas, of Great Bookham, and Mr. A. J. Rowberry, of Woodford, Essex, can compete so successfully.

The self Carnations, we were pleased to notice, made an effective display, and the first prize in the class for twelve was won by Mr. Martin Smith, who had amongst others *Midas*, a beautiful orange-red; *Seagull*, blush; *Cecilia*, yellow; *Exile*, rose; *Lady Hindlip*, brilliant scarlet, and *Mrs. E. Hambro'*, pure white, a flower conspicuous for its purity and width of petal throughout the exhibition. The flowers shown by Mr. R. Sydenham were exceptionally fine; indeed, the two stands were well matched, and amongst the several varieties we noticed a very delicate yellow named *Regina*, which approaches closely the well-known *Germania*. Whether it will eclipse that well-known variety remains to be seen, but its lemon tint will be appreciated. A very successful grower of Carnations, until recently, we believe, an amateur only, is Mr. A. W. Jones, of Handsworth, who grows his flowers in a small garden, but with great ability. In a class for six selfs, the competition being very strong, he won the premier prize with excellent flowers, *Mrs. Eric Hambro'* and the deep red *Mancunian* being worthy of mention. A very close second was Mr. R. C. Cartwright.

The division for the beautiful class of yellow ground Picotees was well filled, happily, as this is a very charming type of flower, and in the chief class, namely, for twelve, Mr. Martin Smith was first, with Mr. Douglas second, and for six Mr. R. C. Cartwright was first. Mr. R. Sydenham had twelve delightful white ground Picotees and was placed first.

Flowers cut from the open border and not dressed in any way were shown well by Mr. Weguelin, St. Mary Church, Torquay, who was a successful prize-winner, and we are pleased to notice that several prizes are offered each year for flowers not touched with the tweezers. In the classes for undressed blooms in vases, Mr. Sydenham staged a very fine collection of twelve selfs, whilst for a corresponding number of fancies or yellow grounds, Mr. Martin Smith was first, and Mr. Sydenham for the delicate white ground Picotees. Mr. C. F. Thurstan, too, showed well in this division. We have seldom seen a more extensive display of single blooms; the competition was tremendous. In the scarlet bizarre division the popular variety *Admiral Curzon* was conspicuous. Mr. R. Sydenham showed *Master Fred* splendidly in the crimson bizarre class. Of pink and purple bizarres, W. Skirving, shown finely by the last-mentioned exhibitor, and Sarah Payne were favourites, whilst of scarlet flakes, Sportsman was the prize-winner, and in the rose-flaked class *Thalia*. The purple flake *Gordon Lewis* won Mr. Sydenham chief award in the class for this type of Carnation. Mr. Cartwright and Mr. Sydenham showed Picotees remarkably well, including such varieties as *Ganymede*, *Mrs. Gordon*, *Muriel*, *Mrs. Openshaw*, *H. Kenyon*, *Ann Lord*, *Mrs. Payne*, *Little Phil*, *Clie*, *Mrs. Sharp*, and *Favourite*. Messrs. Smith, Sydenham, and Cartwright divided the honours in the self or fancy class. *Mrs. Eric Hambro'* was the chief white self, and *Exile*, a clear pleasing rose, *Etna*, scarlet, and *Mancunian* were favourites too. In the classes for those growers who have never previously won a prize, Mr. T. F. Branfield, Stoke-on-Trent, showed well, but there were nearly twenty exhibitors, and this, we think, is an excellent sign for the future. It shows that the number of growers is getting larger and that the prize-winners of to-day will meet keen competitors in the years to come.

It will be interesting possibly to our readers to know a few of the varieties that attracted our attention most at the exhibition. Among the selfs, *Mrs. E. Hambro'*, white; *Her Grace*, blush; *Seagull*, of similar shade; *Exile*, clear rose; *Jim Highgate*, deep clove colour; *Mancunian*; *Verena*; *Mephisto*, intense crimson, an effective kind; *Endymion*; the old but distinct mauve *Garville Gem*, shown well by Mr. Weguelin; *Britannia*, a very fine highly-promising yellow flower; *Winifred*, deep apricot; *Lady Hindlip*, and *Miss A. Campbell*, yellow, were the best. In the fancy Carnation and yellow-ground Picotee

groups, *Perscus*, Mr. Nigel, and *Dervish* were especially noteworthy, and we must mention, too, the beautiful variety *Carina*, which was exhibited freely and well.

The exhibition was varied by Sweet Peas from Mr. Eckford, Wem; tuberous Begonias from Mr. B. R. Davis, of Yeovil; and hardy plants well staged from Mr. W. F. Gunn, Olton; Messrs. Hewitt and Co., Solihull; and Mr. J. White, of Worcester. We hope that this society will continue to prosper, and certainly Mr. Sydenham, the secretary, and all concerned must be congratulated on the display.

A prize list is given in our advertisement columns.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 9.

The meeting held on Tuesday last in the Drill Hall was full of interest in many departments. The Roses and Malmeson Carnations of some recent exhibitions have now given way to other flowers in season, as exemplified in the Dahlias of all sections save singles. Considerable interest centred also in the beautiful and varied collections of hardy Water Lilies that came from several sources, attracting, as well they might, if only from their extreme beauty and exquisite fragrance, a great deal of attention. Seedling Hollyhocks of an excellent strain would appear to render the purchasing of named kinds altogether superfluous, at least from a garden point of view. Of Orchids, there were very few, while hardy flowers, owing doubtless to the recent general and abundant rain, were good and in plenty. Particularly good, too, were the Lilies, a group of *L. aratum* Wittei from Colechester being superb. Gladioli were also a feature, and pleasing in their many shades. The Pitcher Plants from Frogmore and the tall Chimney Campanulas from Syon were each a feature, while Ferns from Edmonton again filled a goodly space. Very complete collections of Gooseberries and Currants, together with the choicest of dessert Cherries, were well shown, these, with a superb collection of fruit from Regent's Park, completely filling one table.

Orchid Committee.

Awards of merit were given to the following:—

CYPRIPEDIUM OLIVIA (*C. tonsum* × *C. niveum*).—This is a distinct and desirable hybrid of American origin. The dorsal sepal is creamy white, suffused with purple, shaded with green in the centre, longitudinally lined with green and purple; the petals each about 3 inches in width, creamy white, suffused with purple, and slightly spotted with dark brown spots. The lip is creamy white, suffused with rose-purple, and veined with a darker shade of purple; the lateral sepal creamy white, veined with green. It has the intermediate characters of both parents in the growth and also in the flower. From Messrs. H. Low and Co., Bush Hill, Enfield.

ODONTOGLOSSUM CRISPUM LEHMANNI (Schofield's var.).—This is the finest *O. Lehmanni* that we have seen, the sepals white, suffused with rose, and spotted in the centre with bright purple spots. The petals are pure white, much crisped at the margin; the broad lip characteristic of the species is unusually large, white at the margin, with a large V-shaped blotch of rich purple covering the whole of the centre, shading again to white in front of the yellow disc and crest. The small plant carried a raceme of three flowers. The plant should improve as it gains strength, and will, no doubt, prove one of the most remarkable *Odontoglossums* in cultivation. From Mr. G. W. Law-Schofield, Newhall Hey, Rawtenstall, near Manchester.

SOBRALIA SANDERIANA.—This is a distinct and desirable form. The sepals are pale rose, suffused with a darker shade of rose, the petals deep rose, suffused with rose-purple, the distinct lip bright reddish crimson, with a line of deep rose in the centre. The side lobes are rose, shading to yellow.

low, and suffused with brown at the base. Two cut flowers came from Baron Schroeder.

Messrs. H. Low and Co., Bush Hill Nurseries, Enfield, sent two lovely forms of *Cattleya Gaskelliana* alba, a dark typical form of the same species, and a large form of *Oncidium Papilio*, the lip being upwards of 3 inches across, deep brown, margined with yellow, and having a large blotch of yellow in the centre, the petals each upwards of 4 inches in length, rich brown, marbled and barred with bright yellow. Messrs. J. Veitch and Sons sent a remarkably dark form of *Cypripedium calanthum* (*C. barbatum* × *C. Lowi*), having the intermediate characteristics of both parents. Mr. J. Douglas, Edenside, Great Bookham, sent a very large form of *Dendrobium formosum giganteum*, the orange blotch in the lip being also unusually dark and distinct. Mr. T. B. Haywood sent *Vanda Batemani* with small flowers, the ground colour yellow, thickly covered with dark brown spots; the lip rich purple, shading to yellow. The outside of the flower is bright rose-purple. M. E. Zollinger, Jenny Villa, Greten, Wollishopen, sent a cut spike of a dark form of *Vanda Sanderiana*. Capt. T. A. Julian, Plymouth, showed a distinct light form of *Cattleya Warszewiczii* (*gigas*), and Baron Schroeder exhibited a cut two-flowered spike of the lovely and valuable *Cypripedium Stonei platy-tanum*.

Floral Committee.

The following plants received first-class certificates:—

FURCRAEA WATSONIANA.—A very distinct and attractive species with widely spreading leaves, each 2 feet in length, having a central stripe of white and a broad dark green margin, between which and the centre narrower lines of white are situated. From Messrs. Sander and Co., St. Albans.

NELUMBIUM NUOIFERUM SPECIOSUM.—A gigantic leaf and blossom of this Sacred Water Bean were shown, the former fully 2 feet across, nearly or quite circular, and the large handsome flower-head also of considerable size; the flowers are nearly pure white, but not inclined to expand in the atmosphere of the Drill Hall. Detached from the plant such things quickly fade. From Her Majesty the Queen, Frogmore (gardener, Mr. Owen Thomas).

The following received awards of merit:—

GLADIOLUS W. B. CHILD.—A variety of the Lemoinei group with large massive flowers of a crimson-purple hue, lightly freckled with white. From Messrs. Kelway and Son, Langport.

GLADIOLUS VESUVIUS.—Also of the Lemoinei group, and having flowers of the richest and most intense crimson velvet. From Mr. Maurice Prichard, Christchurch.

GLADIOLUS BARON J. HULOT (Lemoinei section).—The flowers are of a rich dark violet-purple, shaded blue. A rather poor spike, but a remarkable shade of colour. From Mr. M. Prichard, Christchurch.

CARNATION NOV.—A border kind, and the darkest of the crimson-maroon shaded selfs. A well-formed flower of moderate size. From Mr. Jas. Douglas, Edenside, Great Bookham.

CHRYSANTHEMUM MILLE MARIE MASSE.—A capital bunch of this extremely popular early-flowered variety. The colour is a warm rosy lilac, tinted in the centre with yellowish bronze. From Mr. T. B. Haywood, Woodhatch, Reigate (gardener, Mr. Salter).

NYMPHEA MARLIACEA IGNEA.—This is one of the gems of the highly-coloured forms, and not only handsome in point of colour, but large and showy also. The petals, which are numerous and well imbricated, are of a cherry-crimson hue, very bright and effective against the cluster of orange stamens in the centre. From Mr. A. B. Freeman-Mitford, Moreton-in-the-Marsh, Gloucestershire (gardener, Mr. J. Garrett).

Messrs. Wm. Paul and Son, Waltham Cross, sent a most effective group, prominent in which was a fine lot of seedling Hollyhocks, representing every shade of colour in these showy flowers.

The spikes were cut almost their whole length, and, being densely flowered, formed not only a fine group, but gave an excellent impression of their value in the garden. There were some fifty spikes set up in white, rose, buff, yellow, salmon, blush-scarlet, and lake, besides intermediate shades. The flowers were of good size individually. A good assortment of Phloxes included several new kinds, the most prominent being Lord Rayleigh, violet-blue, the nearest approach to blue of an acceptable shade that we have seen in these flowers. Of the others, Albatre, white, dwarf; Meteore, rose-salmon; Etna, scarlet; and Adonis, salmon-scarlet, were the best. A fine batch of *Yucca flaccida* in flower, together with a highly promising golden Yew called Waltham Golden, a selection from a large bed of seedlings, were also shown. Besides being much brighter than the Irish form, the Yew is also denser and much more uniform in growth (silver Flora medal). A fine group of *Nepenthes* was set up by Mr. Owen Thomas, gardener to Her Majesty The Queen, Frogmore, and, arranged over a ground-work of Maiden-hair Fern, displayed the pitchers to advantage. The collection included the following varieties of this important group: *Intermedia*, *Worthiana*, *Curtisi superba*, with long and dark pitchers; *Wrigleyana*, a very handsome form; the well-known *Rafflesiana*, *Morganie*, with red pitchers; *Mixta*, *Mastersiana*, *Crinum*, very fine pitchers; *Hookeriana*, *Burkei*, *Dicksoniana*, &c. Well-flowered examples of *Acalypha Sanderi* (*hispidula*) and the pretty variegated *Abutilon Swatzi*, with silvered foliage, were also noted in this group. The Pitcher Plants were raised on pedestals to a good height and in this way appeared to advantage (silver-gilt Flora medal).

Mr. H. B. May, Edmonton, brought together a collection of *Nephrolepis*, numbering some twenty-four species and varieties, which is the genus in its entirety as known to cultivation. Some of the most distinct are *acuta* with dark rachis, *pluma*, *tuberosa*, *ensifolia*, *Faulkneri*, *Duffi* (very dense), *cordata undulata*, *rufescens tripinnatifida* (very erect habit), *exaltata multicrepis* with curiously forked pinnae, *pectinata* and *philippinensis*, approaching each other in appearance, *cordata* and its varieties *compacta* and *crispa*, and the golden green-tinted *N. exaltata* (silver-gilt Banksian medal). A well-arranged group of fine-foliaged and flowering plants came from Mrs. Abbott, South Villa, Regent's Park (gardener, Mr. G. Kelf). The group contained some exceptionally fine and well-grown examples of *Areca lutescens*, one of the plants, a fine clean grown specimen, being nearly 15 feet in height, in the centre, and two others nearly 10 feet high at intervals in the background, as it were; *Kentias*, *Phoenixes*, *Coryphas*, and *Cocos* in variety were among the other Palms employed in this extensive arrangement. Such things as *Crotons*, *Caladiums*, *Pandanus*, *Cannas*, *Aralia Veitchii*, *Acalyphas*, *Asparagus*, *Lilium speciosum* varieties, &c., being tastefully arranged and grouped together, Maiden-hair Fern with other small plants forming the groundwork and margin. The entire group must have been nearly 50 feet in length. A silver-gilt Banksian medal was awarded. From Langport the Messrs. Kelway and Son brought an extensive assortment of *Gladioli*, mostly of the *gandavensis* section, a long table being filled with these and hardy perennials. The *Gladioli* had apparently been suffering from the long-continued drought, the spikes, indeed the flowers generally, were not up to the usual high standard of excellence. There were also many beautiful *Gaillardias* in variety, as also *Eryngium planum*, *Eryngium alpinum*, and *Eryngium Oliverianum superbum*, the bluest of the tribe. The white Caucasian *Scabiosa*, *S. caucasica* alba, was in good order, the flowers fine and clean. *Rudbeckia Golden Glow* and *Helianthus Soleil d'Or* were also noticeable. The curious *Mibauxia campanuloides* was also included (silver Flora medal).

The Water Lilies were interesting, visitors thronging round the all too small exhibits of these beautiful flowers. The whole of these

beautiful hybrids are perfectly hardy in the open pond or lake. This is the question invariably put. It is one, moreover, that may be heard being discussed frequently by visitors, and for these reasons, as also the general instruction arising therefrom, exhibitors may not inaptly designate them hardy hybrid Water Lilies, or some such term as would be clearly understood. Several collections were exhibited, that from Mr. A. B. Freeman Mitford, Moreton-in-Marsh (gardener, Mr. J. Garrett), comprising a dozen kinds. These floating in a couple of spacious sponge baths were seen to advantage, the flowers, as also the foliage, being in excellent condition and beautifully fresh. The following varieties of *N. Marliacea* were shown: *Rosea*, *albida*, *Chromatella*, *flammea*, *rubro-punctata*, *ignea*, together with *N. Laydekeri fulgens*, *N. L. fulva*, *N. L. lucida*, *N. gloriosa* and *N. odorata*—a most charming lot (silver Flora medal). Mr. Leopold de Rothschild, Gunnersbury House, Acton (gardener, Mr. Hudson), likewise contributed a beautiful assortment, which besides containing many of the above named kinds, included the lovely little *Helvola* and *pygmaea*, *odorata*, *Seignouretii*, with soft yellow flowers, shaded with rose; *N. Robinsoni*, a finely coloured form, rose to deep rose, and delicately, though freely spotted with white; *odorata sulphurea grandiflora*, *odorata rosea*, exquisitely perfumed and of a most lovely shade; *Aurora*, creamy white; *Marliacea carnea*, *Ellisiana*, a rich crimson, &c., the whole constituting the most complete gathering yet seen. It was distinctly stated that the whole of the Gunnersbury House collection had been grown in the open lake without protection. Some of the earliest planted have withstood 26° of frost with no protection, and it is fully expected the recent additions will be their equal in perfect hardiness. Such information as the outcome of general experience is most welcome (silver Banksian medal). A further lot of these beautiful hardy Water Lilies came from Mr. W. Robinson, 63, Lincoln's Inn Fields, the blooms throughout being strong and vigorous, evidently the outcome of well established examples (bronze Flora medal). The group of *Chimney Campanulas* (*C. pyramidalis compacta*) from Earl Percy, Syon House, Brentford (gardener, Mr. George Wythes), was of unusual interest and splendidly grown; indeed, it would be difficult to surpass the many beautiful examples of which the group in question was composed. The plants had been raised from seed sown sixteen months ago, and were growing in 8-inch pots, the heights varying from 3 feet to 7 feet and upwards. Apart from the main spike or column, which in every plant was densely flowered, were numerous basal laterals ranging from 2 feet high that added greatly to the effect as a whole. Not the least pleasing feature was the varying shades of blue, some very soft and delicate looking. These arranged thinly among the snowy spires, which were more numerous, gave an increased charm to the whole. A setting of Maiden-hair Ferns, with a few tall Palms in the background, completed a very pleasing and beautiful arrangement (silver Banksian medal).

The Messrs. Wallace showed Lilies in variety, the most notable being a group of *L. auratum* Witte, a massive pure white kind, the white of the segments only relieved by the chrome-yellow rib running through each segment. *L. a. rubrovittatum*, *L. Heuryi*, *L. Batemanni*, *L. speciosum album novum*, *L. longiflorum giganteum*, and *L. chalcedonium* were also shown. The same group contained quite a host of the hybrid *Moutbretias* (*Tritonias*) in some eight or more kinds, all very beautiful, and many *Gladioli*, mostly of the Lemoinei group, which appear to be increasing in favour owing to their strangely beautiful colours and lessened formality. *G. Saundersi*, with orange-scarlet flowers, being in some quantity. A few *Calochorti*, probably the last for the season, and a beautiful lot of border Carnations were also noted. A couple of pans were also filled with *Sternbergia macrantha*, a huge Meadow Safron-like blossom of a golden hue appearing to each bulb. The bulbs, which are part of a recent

importation, were of fine size, and emitting roots abundantly as the result of a few days in the soil. This should make a fine plant for selected positions in the border or rock garden (silver Banksian medal). A capital assortment of choice hardy things came from Mr. Prichard, Christchurch, the bunches freely disposed and nicely arranged. Here the white Scabious was in plenty. The curious *Zygadenus elegans*, the brilliant *Zauschneria californica* and its variety *splendens*, *Dianthus Atkinsoni*, rose and white Everlasting Peas, *Clematis integrifolia* and *C. coccinea*, fruiting examples of *Podophyllum Emodi*, *Echinops sphaerocephalus* and *E. nivalis* (both excellent), Parker's crimson variety of *Lobelia cardinalis*, *Gladiolus Lemoinei*, a fine bunch of *Aselepias tuberosa* with handsome heads of orange flowers, the plant being rarely seen in such condition, and a nice lot of hybrid Water Lilies were also included in this group (silver Banksian medal). Hardy flowers came also from Messrs. Cutbush and Son, Highgate, including border Carnations, Phloxes, Platycodon grandiflorum, several *Eryngiums*, *Papaver nudicaule*, &c. (bronze Banksian medal). Border Carnations in variety, but not named, came from Lord Hillingdon, Hillingdon Court, Uxbridge (gardener, Mr. Allan), and included many beautiful flowers. Others from Mr. James Douglas included some excellent things. A fine exhibit of the pure white border Carnation George Maquay was set up by the Messrs. Veitch and Sons, the flowers cut with buds and full length stems, showing its value in a cut state.

Annuals also in great variety were set up by the same firm, the Sweet Sultans and Lavateras being most charming. A few choice shrubs, &c., such as *Pavia macrostachya*, *Cornus macrophylla*, the pure white *Eucryphia pinnatifida*, and the blue-berried *Coprosma aerea*, were also included. Flowering branches of *Gloriosa superba* came from Mr. Crook, Forde Abbey, and a fine white Rose (Mrs. Stephen Treseder) from Mr. S. Treseder, Pwyll Coeh, Cardiff.

One or two collections of show and Cactus Dahlias prove the near approach of early autumn, but the flowers generally are not yet so fine as they will be later on. A rather good lot was that from Mr. J. Walker, Thame, Oxon, embracing show, fancy, Cactus and pompons, all in nice fresh blooms. Show kinds were also good (silver Banksian medal). Another exhibit came from Mr. Mortimer, Farnham (silver Banksian medal). Messrs. Webb and Brand, Saffron Walden, had a display of double Hollyhocks, but it is scarcely possible to judge of the merits of varieties by single blooms. A bronze Flora medal was awarded. A seedling *Croton*, *C. Wentworthianus*, the result of crossing *C. interruptus* with *C. Weismanni*, came from Earl Fitzwilliam, Wentworth Woodhouse, Rotherham (gardener, Mr. J. Hughes). It is a showy and well-marked kind, but in the small plants shown it would be difficult to say if there is any improvement on the many beautiful things already in commerce; the tendency is towards *C. interruptus*, though the stems give the colour of *C. Weismanni*.

Fruit Committee.

Messrs. Veitch and Sons, Ltd., staged 100 varieties of Gooseberries in trays. This was certainly one of the best exhibits of Gooseberries ever seen at the Drill Hall. In the red varieties one could not fail to notice such splendid kinds as Beauty, Clayton, Companion, Crown Bob, Dan's Mistake, Duke of Sutherland, Foreman, Forester (one of the best reds), Highlander (a grand berry), and Whinham's Industry. Of yellows, Langley Beauty, a variety given a first-class certificate, was very fine. Gipsy Queen was also good, as were Leander, Gunner, Leveller, Magistrate, Oyster Girl, Railway, Pretty Boy, and Trumpeter. Of green kinds there were some twenty dishes, and amongst these are found some of the best flavoured. Duster, Green London, Keepsake, Matchless, Plunder, Stockwell Surprise, Telegraph, Souter Johnny, and Tom Turner were very fine. In the white section

some of the berries were smaller, but Alma, Careless, Eagle, Mitro, Progress, and Queen of Trumps were very fine. The new Langley Gage was well represented. There were at the back several stands of fruiting sprays both of Gooseberries and Currants. Of the Currants twenty-five varieties were shown, Black Naples, Ogden's Black, Lee's Prolific Black, the Cherry Currant, La Constante, La Hâtive, La Versailles, Mammoth, Warner's Grape, White Dutch, and White Cut-leaved were the best. Some six varieties of early Apples, including Mr. Gladstone, Irish Peach, Early Harvest, Julien, Red Astrachan, and Oslin were staged, with Doyenné d'Été, Jargonelle, and Citron des Carmes Pears. A gold medal was awarded. The next best collection of fruit was doubtless that shown by Mr. Kelf, South Villa, Regent's Park, N.W. Plums in pots formed a background, the varieties being Coe's Golden Drop, Jefferson's, and Cox's Empress, with some gathered fruits of Kirke's, Reine Claude, Le Comte d'Athens, Green Gage, McLaughlin's Gage, Magnum Bonum, and Early Transparent Gage. A very fine lot of Royal George, Bellegarde, and Barrington Peaches was also staged, with Black Hamburg, Madresfield Court, Muscat of Alexandria, and Buckland Sweetwater Grapes, and some half dozen Melons in variety (silver-gilt Knightian medal). A very good lot of fruit in variety was staged by Mr. Miller, Ruxley Lodge Gardens, Esher. A few of the Peaches were scarcely ripe. Royal George, Violette Hâtive, and Alexandra Noblesse were excellent, as were Waterloo and Early Alexander from open walls. Cherries with some half dozen varieties of Melons, Apricots in variety, Plums and Gooseberries were included (silver Knightian medal). The Messrs. Rivers, Sawbridgeworth, Herts, sent a small collection, in which were some grand Cherries in variety, with a splendid basket of Early Rivers Nectarine and Grand Duke, and Golden Transparent Plums (silver Banksian medal). The Messrs. Harrison and Sons, Leicester, staged twenty varieties of Broad Beans, these in many cases being excellent. From the Society's Gardens, Chiswick, were sent dwarf French Beans. Veitch's Early Forcing was the heaviest cropper, and a grand pod. Gibson's Bean and Early Negro from Messrs. Dammann, Naples, were no advance on existing varieties. The Committee decided it was best to see all the varieties in a growing state at the Gardens. A dish of Scarlet Runner Beans came from Mr. T. W. Aimes, Ashford, Kent, and a nice dish of Snowball Turnip came from M. A. Dean, Richmond Road, Kingston, to compare with a variety recently given an award. Melons were sent by two exhibitors, Mr. J. Crook sending a nicely netted pale green flesh variety named Forde Abbey Seedling, but lacking flavour. A new seedling named Capps' Seedling, a white flesh, came from Mr. Capps, Padoekhurst, Crawley, but much too ripe. Mr. Roupell, Roupell Park, S.W., sent Mr. Gladstone and Irish Peach Apples, excellent for the season. The Messrs. Veitch sent a new fruit, the Raspberry Blackberry, the result of crossing the Raspberry with the Blackberry. The berries are late and very prolific, and have a nice brisk acid flavour. Messrs. Kelway, Langport, sent a new fruit, the Strawberry Raspberry, but the committee were not allowed to taste the fruits, so could give no idea as to their value. Mr. Carmichael, Pitt Street, Edinburgh, sent a new Strawberry Britannia, which looked like a poor Waterloo. If well grown it should make a good late variety. Mr. Blake, Clandon Park Gardens, sent Currant La Versailles to show its close affinity to the new Red Currant, Comet. The committee desired a trial to be made at Chiswick of the two varieties, some of the members thinking Comet the older kind.

The weather in West Herts.—Taken as a whole the past week proved very cold for a summer month. On the 7th the temperature in shade never exceeded 55°, which is the lowest maximum reading recorded here in August since

1888. Most of the nights were also cold, the exposed thermometer on one of them falling to within 8° of the freezing point. Consequently the ground temperatures have fallen, the reading at 2 feet deep being at the present time about 1°, and at 1 foot deep about 3° below their respective averages. Some rain fell on every day, but the total for the week only amounted to about half an inch. No rain-water at all has now passed through either of the percolation gauges since the middle of July. On the 4th the sun shone brightly for twelve hours, but on several other days there was a very scanty record of sunshine.—E. M., *Berkhamsted*.

NOTES OF THE WEEK.

Carnation Lady Ardilaun.—We learn that this Carnation, which was figured in *THE GARDEN* of February 5 of the present year, received the first prize in an immense competition at the Midland Carnation and Picotee show at Birmingham on the 5th and 6th inst. for the best specimen fancy in the show. It was shown by Mr. Weguelin, St. Mary Church, Torquay.

Seeding Carnations.—Herewith I send you for your opinion a box of seeding Carnations. The one marked "No. 11" has over 200 buds and flowers on one plant. I consider some of them are equal to named varieties. I grow about forty kinds.—W. Wilson, *Lamorbey Cottage, Sidcup, Kent*.

*** Very bright and handsome seedlings, and, as you say, as good as many named varieties. These, however, are usually sent out more in the interest of the raiser than of private growers, and are mostly useless from any point of view save that of the exhibitor.—Ed.

Astilbe Thunbergi is now a very showy plant, with its handsome panicles of creamy white flowers slightly arching at the tip. The plant is naturally of a vigorous habit, attaining to nearly 4 feet high, and bearing many of its showy plumes when the plants are established. Given a strong and fairly good soil, the plant is not slow to make headway, but attaining the greatest dimensions where moisture is present. In the strong soil in the Botanic Gardens, Birmingham, the plants in this latter position are very effective. Some capital examples are likewise flowering in the Kew collection.

Bambusa palmata at Glasnevin.—The poor specimens of this Bamboo one so generally sees give a feeble idea of the beauty of established plants in congenial situations. As often seen, the palmate Bamboo looks greatly inferior to such fine species as *B. Metake* and others of the genus. Effective plants of *B. palmata* are seldom met with, and until I saw one this summer in the Royal Botanic Gardens at Glasnevin it did not hold as high a place in my estimation as several others. It was impossible, however, not to recognise the beauty of the Glasnevin specimen and to agree with a high authority that the palmate Bamboo is one of the best of the genus.—S. ARNOTT.

Patrinia rupestris.—It may not be out of place to observe regarding my note on this plant at Kirkconnel (page 112) that *P. rupestris*, as best known and as described in the "Dictionary of Gardening," has yellow flowers. The plant to which I referred, and which has white flowers, was, if I mistake not, sent out from Newry. I have seen plants with poorer flowers in other gardens also with white blooms and also grown as *P. rupestris*. It may, however, not be a *Patrinia*, but a *Valerian*. According to the "Kew Index," *P. intermedia* and *P. sibirica* are distinct species. *P. rupestris* of Bunge is the former, and *P. rupestris* of Steudel the latter. A note from Mr. H. Sello-Leonard leads me to think it better to pen this in case of misunderstanding.—S. ARNOTT.

Cytisus nigricans.—Although now past its best, this Broom is still pretty and bright. During July it is one of the most charming of the *Cytisuses* and *Genistas*. It carries its flowers on tall, slender, perfectly erect spikes terminating

the present summer's growth. They commence to open at the bottom first, and a long succession of them extends over many weeks. They are bright yellow, the name of nigricans referring to the peculiarity of the plant turning black when dried. As soon as it has done flowering the upper part of the shoot bearing the seed-vessels should be removed, these being so abundant as to weaken the plant if the whole of them are left to ripen. They may be shortened still more in spring before growth recommences. By this means the plants may be easily kept about 3 feet high, and always bushy and compact in habit. It is very easily increased by means of seed.

The Chimney Bellflower (*C. pyramidalis*).—I enclose a photograph of some plants of *Campanula pyramidalis* which are now standing in the front hall at Hatfield House. There are six plants, four white ones and two blue ones. They are each from 7 feet to 8 feet high. The seed was sown the first week in March, 1897, and the seedlings were pricked off into pans, then when strong enough potted into 4-inch pots and grown on in a cold frame. In June they were shifted into 6-inch pots and placed on a bed of ashes out of doors till bad weather came. Then they were placed in a cold frame again, and kept there during the winter with very little water. They were potted again in February of the present year into 9-inch pots, and brought into the vineries in April, where they were grown, being brought from the early vinery to the late one, as the vines covered the roof.—CHARLES A. HEATH, *Hatfield House, Hatfield.*

Indigofera Gerardiana.—There are few more charming shrubs flowering out-of-doors during the month of August than this Himalayan *Indigofera*. Planted against a wall its growths usually survive the winter, but in the open it is killed to the ground almost invariably. It sends up a thicket of shoots each 2 feet to 3 feet high, which are luxuriantly furnished with dark green leaves, and which in themselves make the plant distinctly handsome. It is from the axils of the leaves that the spikes of bright rosy flowers continue to appear from July up to the end of September. Each spike is 3 inches to 4 inches long with the flowers thickly clustered on the upper part. The one drawback to this shrub is its lateness in starting into growth. It is not till June that the old stools become really furnished with young shoots. For this reason it is unsuitable for planting in large groups by itself. It makes a pretty undergrowth for taller things provided it is not unduly shaded.—B.

Dianthus Knappi.—If for no other reason, this distinct pink is worth a position in the rock garden for its exceptional colour, a deep sulphury yellow shade. The species is not, so far as present experience goes, to be reckoned amongst robust growers, but doubtless if seen in a colony would have a very pretty effect. The individual flowers are about three-quarters of an inch in diameter, and appear in small clusters on stems nearly or quite a foot high. Such pests as mice, voles, slugs, and the like are exceedingly fond of the shoots and even the stems and leaves, the two first being responsible at times for well-nigh clearing it away completely. Possibly a syringing of strong quassia water about the plant would render it distasteful for the time, and as the plants so treated retain the acrid taste for some weeks, it is at any rate worth a trial, not merely with the above, but with other choice things that are too frequently attacked and lost before one is aware of anything wrong.

Asilbe Silver Sheaf.—This distinct and handsome kind, so well shown in fine flowering clumps by Mr. Prichard at the Drill Hall meeting a week ago, does not appear to be generally cultivated or even generally known. There is, however, not the least doubt of its beauty and worth, particularly in established clumps such as those now referred to, and it is doubtless but a question of time before we see this handsome plant taking its true place in the garden. In the buff-white tone of the plume-like panicles of blos-

soms there is quite a distinct character, which is as striking as it is novel and effective. The plant is possessed of a good vigorous habit, perhaps rather too rigidly erect, if the examples referred to were representative of the kind, yet at the same time quite distinct from the various members of this race and a good all-round plant withal. Moisture-loving, of course, like most of its race, the plant will offer no difficulty to the cultivator if a cool and rather moist place be given it.

The Kilmarnock Orchis.—While at Kirkconnel lately I had the opportunity of again seeing the plants of *Orchis maculata superba*, to which Mr. Harper referred in his useful note in THE GARDEN a few weeks ago in dealing with the question of removal or non-removal. Unfortunately, Mr. Harper was away on a holiday, and one had not the opportunity of discussing the matter with him. It may be observed that the soil in the gardens at Kirkconnel is apparently very suitable for hardy Orchids, and it may be that in soil such as this the Kilmarnock Orchis with a top dressing annually does not dwindle away. Mr. Harper has a special liking for the hardy Orchids, and manages to grow them well, soil and situation being alike favourable. The spikes produced on established plants are very handsome, but, as bearing on the question at issue, it may be said that those on plants only divided last year were quite as good, and the latter showed no sign of being any the worse for their removal. Grown in ordinary gardens, the experience of many is that occasional removal is necessary.—S. ANNOT.

Spartium junceum.—This, the Spanish Broom, is the brightest and most showy of the yellow-flowered shrubs in bloom during July and early August. The flowers are borne on erect spikes, each 6 inches or 8 inches high and each one is 1 inch across, the standard petal being especially noticeable for its breadth and size. The flower is, indeed, individually the largest among the hardy Leguminosæ. The plant is not uncommon in gardens, but as a rule one sees only one or two scattered specimens of it. To get the brightest effect it should be planted in groups of not less than a dozen plants, not necessarily close together, but near enough to catch the eye at once. The finest effect I have seen produced in this country by the Spanish Broom is at Taplow Station, on the Great Western Railway. Whoever planted the shrubberies about the station appears to have had a big stock of this shrub on hand. At all events it is scattered freely all round the place, and at this or a slightly earlier season makes Taplow one of the brightest railway stations in the kingdom. It grows usually some 8 feet to 10 feet high, occasionally more. It has scarcely any foliage, only a few scattered narrow leaves on the soft pitby stems. In a small state it should frequently be stopped so as to induce a bushy habit. It does not need a rich soil, but keeps at a more convenient size and flowers better in a comparatively poor one.—B.

Omphalodes Lucilæ.—It is rarely that we see strong tufts of this alpine plant growing or flowering as freely as one could wish. It is seldom safe to plant it unless in some well-prepared mixture of soil, and so long as this is light, well drained and of good depth, its composition is of little moment. It is, however, a plant that even the most experienced cultivator of alpine must watch. I have but once seen the plant quite happy, growing and flowering freely in a semi-naturalised sort of way, and this on a small, quite unpretentious bit of rockery in the late Mr. James Atkins' garden at Painswick. Here the sky-blue flowers were jutting out everywhere on this little slope of made soil, to which slate chippings had been freely added. The common gravel of the district, a magnesian limestone, was also strongly in evidence, and not only on the rockery slope, but large tufts in pots were crowded with crowns. Such tufts as these may with great care be divided in early spring just

when growth has fairly begun; to attempt the division of the plant when dormant would mean ruin. In an equal mixture of fibrous peat and strong loam, with sharp sand and pounded brick rubbish, some success has been secured both with divisions and seedlings. The latter are very slow, and must be watched continually on account of slugs. Cuttings when such can be had will root in pure sand, kept very moist and nearly dark, but if allowed to droop will rarely if ever recover.

Saxifraga Hirculus.—This is not only one of the most distinct of this genus, it is also one of the most uncommon, particularly so in good condition. It is a plant that in some gardens appears to thrive in various positions without special care, while in others considerable care may be bestowed upon it with but little success. The large golden yellow blossoms resemble at a short distance those of some of the *Helianthemums* in shape and colour, while the foliage is prostrate or nearly so. The species is reputedly a swamp or bog-loving kind, though often in this position the plant is flowerless and more or less generally a failure. One of the essentials to the bog treatment is that the plants also should be in the full sun. Where the opposite position is selected the plant frequently is not happy. Some years ago I had this plant, or, more strictly, a major form of it, doing well in the drier parts of a small artificial bog, rendered dry in the sense that the surface was undulated, and thereby accommodated a greater variety of subjects. The soil in which the roots were was never dry nor wet, but a uniform cool and moist condition prevailed, and in this the plant grew and flowered as well as increased. Some large pot plants were equally satisfactory and very pretty when the golden yellow blossoms were expanded. Where the moist conditions cannot be given, this pretty species will not mind a rather shady position in good soil in the rock garden.—E. J.

PUBLIC GARDENS.

Recreation ground for St. Albans.—Mr. and Mrs. Charles Woollam have given a recreation ground to the St. Albans City Council for the use of the inhabitants. The land, which is near the centre of the city, is seven acres in extent, and is a most valuable gift. This is the second recreation ground presented to the city, the Clarence Park having been handed over to the Corporation by Sir J. Blundell Maple, M.P., four years ago.

The Assistant Director of Kew Gardens.—The Colonial Secretary, says the *Pall Mall Gazette*, having appointed Dr. Morris to organise the new Botanical and Agricultural Department for the Windward and Leeward Islands, the post of assistant-director of the Royal Gardens at Kew becomes vacant towards the close of September. So far as can be ascertained, it seems doubtful whether the vacancy thus created will be filled up for some time to come. The assistant-directorship is worth £700 per annum, and Dr. Morris goes out to the West Indies at an initial salary of £1000 per annum, exclusive of travelling and other allowances.

Roses deformed.—Can any Rose grower explain the cause of the double and treble centres so common with Rose blooms this season? Is the dry winter, the late cold spring, or insect pests to blame for this disfigurement?—B. D. K.

Drying flowers.—Is there any way of pressing flowers, especially blue ones, by which they retain their colour when dry?—C. B. C.

Names of plants.—*Evelyn*.—1, the Lizard Orchis (*O. hircina*); 2, *Betonica grandiflora*.—*Birkdale*.—Morning Glory is the English name for the genus *Ipomoea*.—*V. Moody*.—*Cyrtanthus McKeni*.—*E. M.*—*Hutchinsia alpina*.—*F. M. B.*—*Inula britannica* (Linn.).

STOVE AND GREENHOUSE.

ACHIMENES.

THESE pretty plants are not so much grown as formerly or so well cultivated in the majority of instances, and I was the more pleased to see a fine lot of the old Mauve Perfection flowering finely in quite a cool greenhouse recently. One of the greatest drawbacks to their culture is, that being usually cultivated in rather warm, moist houses, they soon suffer when brought into a dry or cool conservatory. If they were grown cooler and in rather more light from the first the foliage would be harder, and probably the flowers would not be so likely to drop. Being so easily grown and taking up practically no room during the winter, they would prove very useful in gardens where plant houses are small and few and the majority of the plants for decoration have to be grown as best they may in the fruit houses. Dry roots are obtainable in spring, and should be potted for succession during February, March, and April, or even a little earlier where a display is looked for in late spring. They are grown in a variety of ways, pots, baskets, or pans being used, and specimens in 9-inch pots, made up by shifting combs that have been started in the 3-inch size, are very pretty in summer. Perfect drainage of the pots, both for starting the combs and for flowering, is essential, for though the roots delight in ample moisture, they cannot stand anything like closeness or a waterlogged state. For this reason use light soil in an open condition, dried cow manure broken in lumps and leaf-soil being added to light fibrous loam. The combs may be buried about an inch below the surface, a good sprinkling of silver sand around them preventing their decay. Give very little water until the top growth is getting strong, but after this a full supply is needed. The plants like a partially shaded position, not too far from the roof-glass, as it is important the stems be not drawn. It is not advisable to give permanent

shading, a piece of white garden net of rather open mesh being the best protection. In no case must the sun shine direct on the foliage, but in a vinery or early Peach house the foliage acts as a sufficient break. After the flowers are past and the growths begin to lose colour, dry them off gradually in a good light, remove the combs from the soil and place in boxes of silver sand in a cool, dry house, but not near the pipes, where the heat may cause shrivelling.

H. R.

Pelargonium Achievement.—This Pelargonium, which received an award of merit on July 26, furnishes an illustration of the manner in which some names crop up from time to time, and form a very fruitful source of confusion. For instance, the name of Achievement has been previously borne by at least three other varieties of Pelargonium, and as I am speaking only from memory, it is possible that others might be uncarted. The varieties that suggest themselves at the present time as bearing the name in question are, first, a show variety, for which the late Mr. Charles Turner received a certificate in the early 70's, and which was popular for a long time; then a second show, also, I think, one of Mr. Turner's, which is still largely grown, it being one of the most brilliant of all the show varieties, the one drawback being that few flowers are borne in a truss. Besides these a tricolor of the same name was very popular when this class of Pelargoniums was grown by nearly everyone, though I have not met with it of late.—H. P.

Utricularia Endresi.—This pretty plant is not so much grown as it deserves to be, the showy lilac Orchid-like blooms being a welcome addition to the list of stove flowers just now. The plant requires care in growing, not being of a very vigorous habit or able to withstand sudden atmospheric changes. The leaves proceed from a small creeping rhizome which roots freely into a rough, open compost, such as is liked by epiphytal Orchids. Sphagnum Moss and a little peat with a plentiful supply of some hard material, such as ballast or charcoal, suit it admirably. From the time the growth starts in spring the roots should never be dry, the plants

being hung up in a moist stove heat and shaded from the sun. Growth will be rapid, and flowers will appear in plenty in due course. The plant is propagated easily while in active growth by separating the little comb-like growths from the rhizome and growing singly in small pots until the roots gain a hold, when they may be massed. One of the most frequent mistakes in culture is drying the plant too much during the resting season, for, though deciduous, the root-stock or rhizome is not strong enough to stand a long drying.

Rhododendron Nuttalli.—This Rhododendron, illustrated and referred to on page 106, is remarkable from the bright tints that the young foliage assumes, at least when it is grown under glass. Unlike some of the Himalayan species, such as *R. Aucklandi* and *R. barbatum*, the strap-shaped scales that surround the leaf-buds and hang down when growth recommences are not brightly coloured, but green. This, however, is atoned for by the bright hue of the expanding foliage. The upper part of the young leaves is densely covered with small rosy purple scales, which give them quite a velvety appearance, varying in tint according to the standpoint from which they are viewed. On the lower half of the leaf these scales are much less numerous than on the upper and of a rusty brown colour. The rich hue of the young leaf is a good deal influenced by the position of the plant, as it is far brighter when fully exposed to light and sunshine than it is if at all shaded. *Rhododendron Nuttalli* is more tender than some of the Himalayan species, and it also commands a higher price than many of them, but it is such a grand subject for planting out in a large conservatory that it must be assigned a place among the finest members of the genus.—T.

A few distinct zonal Pelargoniums.—It is now some years since that distinct zonal Pelargonium *Souvenir de Mirande* was raised and distributed, and it proved to be the commencement of quite a new race, one of which, *Mme. Jules Chrétien*, was some three or four years ago thought highly of. Since then numerous other distinct forms have been raised, chiefly on the Continent, some of which are certainly quite a break away from commonly-grown varieties. The following were recently noted as very desirable:

Distinction, cherry red at the edges, becoming lighter towards the centre, which is almost white; *Francois Coppé*, much in the same way, but altogether brighter, with a slight violet lustre in the middle of the petals; *Dalia*, a distinct shade of light red at the margin, gradually paling towards the centre; and *Adolphe Brisson*, a kind of earmine-scarlet, lit up with violet around the centre, while it has a light-coloured eye. There are also double-flowered forms of this class, one of which, *Apotheose*, is of much the same colour as *Adolphe Brisson*, but it is somewhat paler. The colours and tints of these varieties are difficult to describe, but their distinct character is at once seen. To these may be added one or two of the spotted varieties mentioned a few weeks since.—H. P.

Ceropegia Woodi.—Outside of botanic gardens *Ceropegias* are rarely seen, and most of those in cultivation are more or less of a climbing nature, but the species under notice forms quite a low-growing procumbent plant, whose thin, wiry stems spread for some distance along the ground. They are furnished with small, orbicular-shaped leaves of a thick fleshy nature. These leaves are on the most vigorous examples about three-quarters of an inch across, but in most instances they are less than that. While the surface of the leaf is green, it is generally so freely marbled with white on the upper surface as to be almost entirely of this latter hue. The flowers, which in some species are very pretty and extremely curious, are in *C. Woodi* much less striking than in several other kinds. They are very plentifully borne, but are little more than an inch long, the tubular portion being pink, while the upper part is brownish purple. When creeping along the ground the slender branches root freely, and often produce small globose tubers at intervals. This *Ceropegia*, which is a native of Natal, succeeds better in the stove than in a cooler structure. Grown in an upended pan or basket it will hang down for about a couple of feet, and its distinctive features are in this way brought prominently under notice. So treated it is just now in good condition in one of the stoves at Kew.—H. P.

Thunbergia alata.—The different varieties of this annual climber are all extremely pretty summer-flowering plants, that may be used in many different ways. Planted out of doors they are very attractive, particularly during a warm summer, and as climbing plants for the greenhouse they are also very pretty. Besides this they are first-rate subjects for growing in suspended baskets, and in this way their brightly coloured blossoms are seen to very great advantage. These *Thunbergias* are readily raised from seed sown in heat in the spring and grown on freely afterwards, being hardened off as they increase in size. A fairly open and moderately rich soil suits them best, and to keep down red spider they should be frequently syringed. The typical *T. alata* has yellow flowers, but there is also a variety (*alba*) in which they are white, and another (*aurantiaca*) deep orange with a purple throat. This last is perhaps the showiest of all, the flowers being so richly tinted and the contrast between the two colours so marked. *T. alata* is a native of South Africa, from whence it was introduced in 1823, and seeds of the several varieties can be obtained from most dealers in such things. Many of the woody species, too, are magnificent climbers for the stove. Some of them require considerable space to be seen at their best.—H. P.

Bouvardia leiantha.—The garden varieties of *Bouvardia* with their larger blossoms have now almost ousted this (one of the original species) from cultivation, yet it is remarkably free flowering, and the blossoms so brightly coloured that it merits more attention than is now bestowed upon it. Introduced from Mexico in 1850, this *Bouvardia* is quite an old plant, and in the early days of my gardening career it was a very popular one. *Bouvardias* as a class are generally regarded as winter-flowering plants, yet many of them will bloom during the summer, especially if they are planted in the open ground. For summer flowering this is one of the best, and for button-holes

and similar purposes at this season it is very useful. Old plants of the several kinds that have done flowering and are no longer required may, instead of throwing them away, be planted out of doors early in the summer, and from then till the autumn they can generally be depended upon to yield a few useful sprays of blossoms whenever required. *Bouvardias* as a class suffer more than most plants from the heavy sulphur-laden fogs experienced in the neighbourhood of London during the autumn and winter months, more especially those forms with hairy leaves. Such havoc is wrought by these fogs, that I have seen a house of *Bouvardias* in flower every leaf of which has been disfigured after a spell of fog.—H. P.

NOTES AND QUESTIONS.—STOVE.

Lachenalia glauca is perhaps the most strangely coloured flower of all this tribe, the exact shade of which is scarcely accounted for, in the specific name here given. In truth the colour would appear rather a mixture of steel-blue and green—certainly a most uncommon shade in any flowering plant. Some examples of this interesting species are now flowering at Kew in the Cape collection of mixed bulbous things.

Stenomesson incarnatum.—This bulbous plant, of which a coloured plate was given in *THE GARDEN* a couple of years ago, is now in flower at Kew, while in another garden I recently noted a flowering specimen of the allied *S. trichromum*. *S. incarnatum* pushes up a stout scape to a height of a yard or thereabouts, while the flowers, which are each nearly 6 inches long, are tube-shaped, spreading somewhat towards the mouth. The exterior of the tube is a kind of salmon-red, while the spreading portion is yellowish, with the extreme points bright green.—H. P.

FRUIT AND VEGETABLE CROPS.

As usual, we are enabled to publish, owing to the kindness of our correspondents, returns of the fruit crops from almost every county in England, Scotland, Wales, and Ireland. Owing to the great quantity of bloom in the early spring it was thought that the fruit crop would be a heavy one. This generally is, as will be seen by the reports, not the case. The very dry winter and the long cold spring have no doubt also had a good deal to do with the deficiency. Plums, too, are very scarce. Strawberries were very late, many of the blooms failing to set owing to the sunless time when the plants were in flower. It will be seen that the fruits of *Royal Sovereign* rotted very badly in some places, this no doubt arising from the large leaves which this variety has. In future it would be advisable to allow a little more space between the lines and also between the plants. Latest of All has proved in most cases a valuable late kind, its only fault being that it does not colour well to the point. The crops of Currants, all varieties, have been excellent, as also Raspberries, among which the variety *Superlative* holds first place. Wall fruit, including Peaches, Nectarines, and Apricots, is very scarce, the blossoms having been cut off when fully open.

The vegetable crops are, as a rule, good, Peas especially having done well in many places, while in others the haulm has been badly attacked by mildew. We hope to give in the course of a few weeks the opinions of the leading growers as to the varieties of Peas which succeed best with them. Tomatoes where grown in the open have had a bad time, and we fear the outdoor crops, unless against walls and protected with sashes and such like, will not ripen.

— All things considered, the fruit crops of 1898 have been and are distinctly disappoint-

ing. Never was there a better prospect as far as the condition of the trees was concerned, but once more it would appear that it is possible to have abundance of bloom and yet but little fruit. The orchard and garden trees were truly a beautiful sight when in bloom, and, in spite of the superabundance, the flowers appeared to be strong and perfectly formed. Then came a long spell of unfavourable weather, more especially cold, chilling winds, and this militated seriously against the prospect of good crops generally. It is not frost that is to blame, as it is noticeable that the crops are the heaviest in many low-lying and sheltered positions or where spring frost most often works serious damage, and the lightest in raised exposed situations. As far as my experience goes, and I have been through several counties lately, there are no highly favoured districts, as was the case last year, when the crops were very heavy in some parts of Gloucestershire and adjoining counties and light nearly everywhere else, but there are sprinklings of fruit everywhere with here and there a tree heavily laden. The chilling winds, coupled with an absence of rain, were all in favour of insect pests, and I never remember seeing so much blight before. Apple blossom was badly infested by aphids before it expanded, the leaves, though in a less degree, suffering from the same pest, while the majority of Plum trees were much overrun by the Plum aphid, the older leaves still presenting a curled, malformed appearance. On all sides we hear complaints of what the caterpillars did to the fruit trees, and the American blight is more in evidence, probably, than ever before. Garden as well as orchard trees have suffered from insect pests and diseases of a fungoid nature. In one instance nearly all the Pear trees are badly affected by the leaf rust, and in another garden Pear and other fruit trees have been much disfigured by the nasty slug-worm. Red spider is very thick on stunted Apple trees, Gooseberry bushes and Strawberry plants. Apricots, Plums and Cherries have been more addicted to gumming than usual, and nearly every primary leaf on Peach and Nectarine trees became blistered and has disappeared. Such a series of misfortunes is enough to dishearten cultivators, especially when they find, as they are beginning to do, that many of their Apples and Pears have a grub in them—a kind of last straw.

As it happens, fruit growers have in numerous instances long since accustomed themselves to regard the open-air fruit crops as somewhat precarious, and those who are wise invariably prepare for the worst. Preparing for the worst ought to include a proper course of spraying with insecticides and fungicides, notably with *Paris green* as an insecticide of the best and cheapest, and if this spraying were to become general, compulsory in fact, better crops of sound fruit would inevitably result every season. Then, again, trees not in a robust state of health ought to be more often fed at the roots. It pays to do this. I will cite an instance. In the two gardens at Cardiff Castle Apple and Pear trees occupy a considerable amount of space and are in a very healthy state. There is scarcely a failure amongst them, and grand crops of Apples and Pears, all good varieties, will be gathered from them this season. All the ground is cultivated, and as the spaces between the trees are cropped with vegetables the fruit trees naturally get their share of the fertilisers used. Shelter may have been partly conducive to this happy state of affairs, but only a portion of the most heavily cropped trees is sheltered, and to good cultivation by Mr. Pettigrew must much of the success be attributed.

In the vicinity of Cardiff the trees in grassed-down orchards are carrying but poor crops. It does not follow that trees generally on cultivated ground are carrying good crops, and this the market growers in the home counties know to their cost, but the healthiest, best and as a rule most productive trees are to be found in cultivated gardens and orchards.

APPLES, the most important fruit of all, are, as before stated, more evenly distributed as regards crops this season than they were last year, and it is worthy of note that the varieties with a strong constitution and with large bold leaves were best able to withstand the trials of the season. Warner's King would appear to be the Apple of the year, but Blenheim Pippin, Peasgood's Nonsuch, Bramley's Seedling, Kentish Pippin, Lord Grosvenor, Winter Codlin and a few other robust varieties have done nearly as well. At Wells Palace and in other gardens where Apple trees are planted against high walls the crops are highly satisfactory; not only are they heavy, but the fruit is large, good in form, clean and colouring well, and the question is, would it not be better to grub up many comparatively worthless Pear and Plum trees against various walls and dwelling houses and substitute Apple trees? I am strongly of opinion that it would. The long spell of dry weather has operated against Apple trees both in gardens and orchards, and at Powderham Castle, Devon, the heavy crops on garden trees have been saved by repeated waterings in addition to the annual mulching of decayed garden refuse, leaves and the like. Since the rains have fallen generally, a great improvement is noticeable in the Apples already in this and other districts.

PEAR TREES against walls are more plentifully fruited than they were last year, but the crops are quite as light in the case of bush, pyramid and orchard trees. In some gardens every wall tree is well furnished with fruit; in others those most exposed to easterly winds are cropped lightly. Much thinning out has been called for, and where neglected or where the trees are starved at the roots, the fruit is undersized and of little value. In a garden at Weston-super-Mare I took particular notice of the heavy crops of fine, clear skinned fruit, and learnt that they had received the full benefit of a good water supply over the trees as well as at the roots. They will pay well for this attention.

PLUMS are plentiful on wall trees sheltered from the colder winds, and the old Victoria seems to have come out of the trying ordeal remarkably well, even trees in the open having a good sprinkling of fruit on them. According to information received, Plums are much more plentiful on trees in market gardens generally than they were last year, and a fairly good prospect may be the cause of foreign Plums, French and Italian, being put on our markets cheaper than they were in 1897.

CHERRIES have been as variable as the other fruits mentioned. Wall trees in places were heavily cropped, the never-failing Morellos doing well generally, but I have seen but few standards carrying profitable crops.

APRICOT trees have been thinly cropped in most gardens, but the fruit has ripened so beautifully as to a certain extent to compensate for shortness of crop.

PEACH TREES flowered well, and where the foliage could be preserved fairly well thin crops are observable. Nectarines would appear to be more heavily cropped than Peaches.

SMALL FRUITS, on the whole, have done well. Gooseberries were a very heavy crop, and so many sound, ripe fruit as at present available are rarely seen. Red and White Currants

have also done well, but Black Currants have been comparatively scarce. They fetched good prices in the market, and if this falling off in the supplies is due, as I believe it to be, to the ravages of the Currant bud mite, they will be even scarcer in years to come. Market growers are beginning to fight shy of them. The heat and drought seriously affected the crop of Raspberries, and the supply has been short accordingly. Strawberries flowered grandly and were not injured by frosts, but they ripened late and the season was short. Royal Sovereign was the variety that gave the best results, and Noble will soon be a thing of the past. Latest of All suffered from red spider attacks, and those who would have late crops ought not to depend too exclusively upon this variety, the old Oxonian or Eleanor better defying a dry season, producing moderately heavy crops of large fruit of fairly good quality.—W. IGGULDEN, *Frome, Somerset.*

SOUTHERN.

Englefield, Reading.—In answer to your letter regarding the fruit crops here, I beg to say that Apples are a middling crop, not at all what I expected at blooming time. Currants, red, white, and black, are good. Cherries, Apricots, and Gooseberries are also good, but Pears are very poor. Nectarines and Peaches are good; Plums only a fair crop. Raspberries and Strawberries have been good.

Broccoli was very good in the spring. Cauliflower has been good. Potatoes are good and free from disease, and Runner Beans are looking well.—J. COOMBS.

Gosfield Hall Gardens, Halstead.—Apples are under: Pears and Plums very scarce; dessert Cherries average, and Morellos very scarce. Peaches and Apricots are average crops. Small fruits, including Strawberries, have been good, but Nuts are poor.—A. KEMBER.

Ottershaw Park, Chertsey.—Apples are an average crop, but Pears in the open are much under, most of the blooms having been killed by the late frosts. On walls there is a good average crop. Peaches, Nectarines, and Apricots are a good crop. The fruits wanted much thinning, and the trees are looking well. Currants and Gooseberries are a good crop and fine in flavour. Strawberries were an average crop, of good flavour, but very late. Plums are an average crop. Cherries poor.

All vegetable crops have been good, but late, and are now suffering from want of rain. Early Potatoes are good but small. The second earlies are turning out well, and are heavy crops. Late ones in gardens and fields are looking very well.—T. OSMAN.

Bearwood, Wokingham.—The fruit crop here and in the neighbourhood is a fair average one: Apples very good, Pears thin, also Plums in places. Peaches and Nectarines are not so good as last year, Apricots thin, Cherries good, Strawberries very good. Bush fruits are plentiful but very small, the blight having been very troublesome on all kinds of fruit owing to dryness of soil through the winter months, and a cold, dull May following crippled the setting of most fruits.

Vegetables of most sorts, both early and late, are excellent. Early and late Potatoes are also good and free from disease.—JAMES TEGG.

Mentmore, Leighton Buzzard.—Apples are under average, there being very few late varieties. Stirling Castle, Mr. Gladstone, Lane's Prince Albert, Keswick Codlin, Seaton House, Ribston Pippin, and one or two others have good crops, and the trees are growing well. Pears are much below an average crop. Strawberries are an excellent crop of good fruit, Latest of All, Oxonian, and Elton Pine being the best late varieties. Royal Sovereign has again been the best main-crop Strawberry. I feel sure this will soon take the place of Sir Joseph Paxton.

Currants have been good and plentiful. Plums are a very poor crop, much below average.

All kinds of vegetables have done well. Peas have been an excellent crop. Potatoes are very good and free from disease. Ninety-fold has been a grand crop of fine, handsome tubers, and not a diseased one to be seen. Windsor Castle is again fine here, and it keeps good till late in spring. It is too early to report on Up-to-date, but the tops are 5 feet high and very healthy. Where the ground is good, all kinds of vegetables are doing well and give every prospect of an abundant supply.—J. SMITH.

Claremont, Esher.—The fruit crop on the whole must be described as above average so far as this garden is concerned. I have not had opportunities of ascertaining prospects in the neighbourhood. Apples are above average, not coming up to the standard indicated by the wonderful profusion of bloom, but yet a very good crop. Trees are generally clean, some few being affected by a black mildew. Apricots are below average, but the fruit is large and of excellent quality. Cherries, especially dessert varieties, are a heavy and long-sustained crop. Peaches and Nectarines are a trifle below average, a sharp frost destroying a considerable percentage of bloom, and very little thinning was necessary. There is, however, a very fair crop and the fruit is of excellent quality. Judging from those already gathered the crop will be late. I am (July 31) still gathering from Alexander and Waterloo. Pears promised wonderfully well, and the fruit appeared to set all right. It has, however, since dropped very much, and the crop is below average. Plums in the open are very scarce, but there are good crops of excellent fruit on protected walls. Outdoor Figs are a good average crop. It is seldom that Strawberries have been so good, and the crop held out well. The only drawback was the rotting of a good many of Royal Sovereign, the plants being too close together. I shall give them 30 inches each way in future. All small fruits are also plentiful and good. Aphis was an early visitor on Black Currants, and the fruit is dirty. Plums and Cherries were also badly attacked, and red spider has been very troublesome on Peaches and Gooseberries, necessitating in all cases copious and frequent washings to keep the trees in health.

Vegetables are good with the exception of Carrots. There is hardly a good bed of the April-sown long varieties in the neighbourhood. February-sown Short Horn kinds are all right. Potatoes turn out well, and at present are quite free from disease. Summer vegetables, as Beans, both dwarf and runner, and Marrows were very late; few of these, if *bona fide* outdoor grown, were fit for use until nearly the end of July. The same remarks would apply to Tomatoes. The outdoor crop is likely to be scanty unless facilities were at hand to push the plants along under cover until they were of a good size.—E. BURRELL.

The Gardens, Clandon Park, Guildford.—Apples are only a moderate crop in these gardens, and in the immediate neighbourhood I think about the same, owing to the dry weather and cold nights. What there are, are falling off wholesale. Pears are a very light crop generally, but what there are appear to be very good, as up to the present there have been no signs of their falling off to any extent. I have three trees of Williams' Bon Chrétien that are not carrying many fruits, but what there are will, I think, be very good. The soil is heavy and deep, so that we are not suffering so much. Of Strawberries there has been a very heavy crop. The late rains filled them out, and at one time it looked like a record crop, especially as regards Royal Sovereign and Latest of All, both of which do exceptionally well here. Owing to the cold nights and lack of sunshine, Royal Sovereign and Noble rotted wholesale. Latest of All, not being so early, did not suffer at all, and the yearling Royal Sovereign were not so bad, as the thinner foliage allowed the fruit to dry. I did not get many Veitch's Perfection, but what there were were of

splendid flavour and fruit very firm. I think it will crop well when we get stronger runners next season. Stone fruit is rather below the average. Rivers' Early Prolific Plum is ripening on south and east walls, and the trees are thickly covered with nice-sized good-flavoured fruit, good for both cooking and dessert.

Vegetables are at the present time doing fairly well, but owing to the dry time are not growing very fast. Where the ground has been well worked and deeply trenched things are looking well, but where this has not been done, Carrots in many cases are burnt up like hay and other things are suffering. Early and mid-season Peas have been exceptionally good, but unless we get rain the late kinds will be almost worthless. Early Potatoes are very good. They are showing signs of ripening off now, and if we get too much rain they will probably grow out.—H. W. BLAKE.

Burton Park, Petworth.—Apples are a poor crop in this neighbourhood, in some orchards none at all. I have a nice crop of some late sorts at the bottom of an orchard, but the majority of the trees are bare. Pears are a light crop also, both on the walls and in the orchards. Cherries have been plentiful on walls, but on standards, where exposed, the crop is thin. Gooseberries, Strawberries, Currants and Raspberries have been abundant, though I hear that Black Currants in some quarters were scarce and the prices high. Strawberries had a short season and were very late in coming in, being fully a fortnight behind last season. Royal Sovereign was very fine and good.

All Potatoes about here look well, and there is every prospect of a good crop. Marrows and Beans (Runner and French) were very late in coming into bearing through the cold weather experienced in June. It was the 26th of July before I gathered the first dish of French Beans outside. Peas have been splendid. Onions in this neighbourhood have the mildew badly as a rule. All other crops, winter stuff in particular, look fairly well.—ALBERT E. GOODEN.

Syon House, Brentford.—The fruit crop may be termed an average one in this district. Apples are a disappointing crop, as with a bountiful promise all hopes were shattered by the very bad weather early in May, as the bloom was so badly injured. I have trees with some fruits on the sheltered side, and scarcely a single fruit where exposed to the cold blast. This may be termed a Codlin year, as these trees usually bear profusely every two years, and they are fairly laden with fruit, the heaviest croppers being Manks, Keswick and Lord Grosvenor. Some other cooking varieties are an average crop. Alfriston, Lane's Prince Albert, Lord Derby and Warner's King are good, whilst most dessert varieties are poor. King of Pippins, which rarely fails with me, is the heaviest crop, and there is an average crop of a few others, but many trees have not a single fruit, these, unfortunately, being the long keepers, and they will be a great loss. Pears, except in one or two instances, are a complete failure. My best crops are on a low south wall in a sheltered garden. Trees fully exposed are almost barren of fruit. I have good fruit on cordons of such varieties as Conference, Louise Bonne of Jersey, Durondeau, Beurré Diel, and Nouvelle Fulvie. Plums are as bad as Pears, as the crop is very poor. My best fruiterers this year are Rivers' Early, Stint and Czar. Many of the trees on an east wall have not a single fruit. Apricots are an average crop, and the fruits are very good. These I usually get in abundance, but the crop is the lightest I have seen during the past ten years. Hemskirk and Breda are the heaviest crops this year. Of Peaches and Nectarines the crop is very light. The earliest Peach was Amsden June, gathered the third week in July. Waterloo, an excellent variety, followed closely. Strange to say, the American Peaches are this season the heaviest croppers, as Hale's Early is bearing a fine crop. On the other hand, I do not think we shall be the losers in the end in having less fruit on some kinds, as we mostly overcrop, and in a dry, hot season the trees are

apt to suffer. Nectarines are better than Peaches. The New Early is a splendid cropper, and will be one of the best wall fruits we have, Lord Napier giving a succession. This is fairly good; other kinds are much lighter. Cherries—I mean the dessert kinds—were never better. The trees have required much care to keep down insect pests, but the crop and quality have been very good. Doubtless owing to their early setting, they escaped the cold winds in May. Morellos on north walls are not so good, as they were later in flowering. Strawberries have borne well. I grow most of the crop as yearlings. Grown thus the crop has been very heavy, though later than usual, and this will make planting late for next year's supply. Raspberries have had a short season, owing to drought and heat, and, though a full crop, the plants need rain badly. Superlative is by far the best in a light, poor soil. Small fruits have been an average crop; Currants good; Gooseberries a thin crop, the trees having suffered when in bloom. Trees on walls are much better.

Vegetables have been excellent. I have had the heaviest crops of Peas I can remember. Potatoes, though later than usual, are a medium crop. Ninetyfold is by far the best early Potato this year. This also is very early in spite of having a large top. It is less affected by frosts than the Ashleaf and is most useful. I have not tried late varieties, but they look well. Mid-season kinds are good and so far free of disease. Ideal is well named; it is a beautiful tuber. The Broccoli and Cauliflower crop was never better; the latter, though late, has been good, and this year I have had a bountiful supply. Tender vegetables, such as French Beans, have been a troublesome crop, as cold nights and frost crippled the earliest plants in spite of protection. There is now an abundant supply, but to keep them going I am obliged to water overhead freely at sunset to keep down red spider. There has been no lack of other things, such as salads and Spinach. Celery has been difficult to get out, owing to heat and drought, but it is now making good progress. In spite of the drought, root crops look fairly well where the soil was given good cultivation. To sum up as regards the vegetable crop, there has been no lack of any kind. Delay in planting will affect the winter and spring supply, and to do the plants justice means adding greatly to labour, never any too plentiful in a private garden.—G. WYTHES.

Kingston, Surrey.—Having during the past month been all over Surrey, my report of the fruit crops is not a roseate one. Apples are very partial. Here and there a few trees are heavily laden, but these are the exception. Where so fruited the lack of sufficient moisture at the roots is causing many fruits to fall, and the rest will be relatively small. Generally the crop is a very thin one, a very long way below what the spring bloom promised. The trees, however, have not appreciably suffered from maggot, and seem to be very clean. Pears are even less in quantity than are Apples. Trees habitually heavily cropped have but one fourth or even less of the average quantity. Such fruits as these are should be fairly good. The season does not specially favour any one variety or form of tree. Even old and regularly fruiting common varieties are no better cropped than others. Plums seem to be even scarcer than Pears, although I have seen here and there some trees well laden, but the fruits are late and small. In one garden in a very warm sheltered position, Damsons on numerous trees were a heavy crop, but that was a rarity. Cherries have been a good crop almost everywhere. Taking trees generally, I have seen little evidence of any form of insect or fungoid attacks, and think, except where trees are very exposed to cold sweeping winds, that they are fairly clean. Because the season so far is dry, there should be no excessive wood growth, and good bud formation. Still, we may have in the autumn heavy rains that would cause new and sappy wood to be formed, which would be detrimental. For the benefit of the trees and a possible next season's crop, it would be better if no heavy rains came until

after leaf-fall. Bush fruits almost everywhere have again shown that they are the most reliable and profitable to grow. Gooseberries have everywhere been a great crop. I have never seen heavier at any time, and the fruits have been fine. Both red and white Currants have been the same. On the bushes and at the scores of county exhibitions I have attended I have found these fruits very fine and good. No doubt this is largely due to the fact that the soil seems to have been moister some 12 inches to 14 inches down than it has been lower, where the roots of tall trees run. Raspberries, where properly grown, too, have been very good and abundant. Strawberries on fairly holding soil have been an excellent crop, but on light loose porous soils they soon gave out. Much depends on the way the soil is prepared for the plants, as some growers stick them in on merely dug ground, whilst others, understanding their requirements, trench deeply and manure liberally, hence they get fine plants and good crops. Royal Sovereign seems to have found its way already into many of the cottage gardens, for cottagers now are very keen to pick up the best they can of good things. The Nut crop is a moderate one. Sometimes both Walnuts and small Nuts are plentiful, in other cases very thin. The crop of cultivated fruit has so far not been all that could be desired, but it might have been much worse. The stone fruits on walls have been fairly plentiful, but these trees suffered more than any others in the spring from fly and blister. It is thus seen that uncovered walls have their drawbacks.—A. DEAN.

Cowdray Park, Midhurst.—Apples are about half a crop. In sheltered places some kinds carry a full crop. Pears on walls are fairly good where protected with nets when in bloom. Trees in the open are very thin, except a very few kinds. Peaches are excellent and trees clean. The fruit had to be thinned considerably. Apricots are an average crop. Plums on sheltered walls are a fair crop where protected when in bloom, but orchard trees are very thin. Sheltered trees in cottage gardens have a fair crop. Cherries are a full crop. Bush fruits are very good, also Strawberries. Nuts are a very full crop, while Walnuts are a failure.

Vegetables generally are up to the present good, but are beginning to suffer from the want of rain. Peas have been very good on well-tilled land, but they are now quite drying out where not watered. For the same reason Runner Beans are not setting. Broad Beans are very good. Carrots are more than usually clean, also Onions. Potatoes will not be large on this thin land, the haulm in many places drying up before the tubers are half-grown.—F. GEESON.

Wycombe Abbey, High Wycombe.—Apples are a poor crop, trees very much blighted. Pears are good. Plums are only fair, the trees in some places much blighted. Cherries have been large and good in quality; Morellos deficient. Peaches and Nectarines are good, the early ones fine and of good quality; Apricots poor, quality good. Small fruits, including Gooseberries, Black and Red Currants, are very fine.

In the vegetable department the effect of want of rain is plainly visible amongst all late-planted and sown crops, and will doubtless materially affect the yield of most of them, whereas the early-planted and sown ones, being more firmly established, will withstand the aridity better and produce far better results in the end. At the present time early-planted Potato crops look very promising, and the crop now being lifted, although not a heavy one, is, as far as quality goes, excellent. Cabbage, Cauliflowers, early Peas, Broad Beans and Shallots have done well, and early planted Brussels Sprouts, winter greens and Veitch's Autumn Giant Broccoli coming in are good. By reason of the prolonged drought having in many places considerably deferred the secondary plantings of the winter stuff, this will probably render the supply of it more scarce next spring than is usual. To meet an emergency of this kind more early Cabbages and Coleworts should be planted.—G. T. MILES.

FLOWER GARDEN.

A HEREFORDSHIRE GARDEN.

DURING the early days of June I was afforded an opportunity of inspecting the interesting and beautiful garden at Underdown, near Ledbury, the residence of Mr. Spencer H. Bickham. Passing through the quaint town, with its numerous picturesque old houses that face the street with gables of Oak and plaster, a gradual ascent brings one to Underdown, from whence an extensive view of the surrounding country is obtained, whilst the house itself is encompassed by gardens in which a choice and carefully tended collection of hardy plants flourishes. The soil is evidently well adapted to the cultivation of Roses, some huge-headed standards being in vigorous health, one specimen of

with which it was associated. *Achillea rupestris* was also in full bloom. Of *Androsace*s, *A. foliosa* and *A. lanuginosa* were both flowering, while *A. carnea*, *A. sarmentosa*, and the Himalayan variety of *A. villosa*, though not in bloom, were particularly healthy in appearance. One of the brightest spots in this portion of the garden was a large patch, a yard or more across, of *Ethionema grandiflorum*, a breadth of bright rose-pink. *Antirrhinum glutinosum*, trailing over the rocks, was a mass of flower, while of *Anemones*, *A. alpina*, *A. alpina sulphurea*, *A. narcissiflora*, and *A. pennsylvanica* were blossoming, as was *Anthyllis montana rubra*, while the blue *Aphyllanthes monspeliensis* was bearing flowers on its Rush-like leafage. The little *Arenaria balearica* covered the stones with the delicate tracery of its countless minute white blossoms, and the

Bickham, the blooms of which are of an intense shade of pink. *Dodecatheon splendendum* was in fine bloom in a lower level of the garden, and the Edelweiss (*Graphalium leontopodium*) gave promise of flower at an early date. *Erigeron Roylei* was bright with its purple flowers, and *Erinus alpinus*, which in common with *Linaria alpina* grows freely from self-sown seeds, was also blooming. The creeping form of *Genista pilosa* was covering the rocks with blossom-laden shoots, and a large plant of *Geranium argenteum* was in flower, as were *G. cinereum*, *G. macrorrhizon* and *G. subcaulescens*. In the bright morning hours the Sun Roses (*Helianthemum*) were a delightful picture, the plants being clothed in varied shades of yellow, red, pink, and white. *Hutchinsia alpina* was producing its flowers, as was *Iberis Pruiti*, while *Libertia formosa* and *L. grandiflora* were also in bloom.

The light blue flowers of *Linum narbonense* crowned its slender stems, and *L. monogynum* was also in bloom, as were *Lithospermum Gastoni* and *L. prostratum*. *Lychmis Lagasce* had taken up its position on an old wall, where it was flowering freely. *Maianthemum (Convallaria) bifolium* was bearing its delicate white bloom-spires, while the brick-red flowers of *Malva lateritia* and the pinker blossoms of *M. Munroana* were studding the prostrate foliage. *Onophalodes Lucilia* was the picture of health, and fine plants were bearing their porcelain-blue flower sprays in quantity. *Onosma tauricum* seemed also perfectly at home, and hung its pendent yellow bells from a higher portion of the rockery. *Oxytropis campestris* and *O. strobilacea* were in flower, as were *Pentstemon glaber* and *P. Scouleri*, the latter growing in large masses 2 feet and more across. The flowering season of the dwarf *Phloxes* was past at the time of my visit, but *Ranonda pyrenaica* was in fine bloom on a flat bed, it being found to succeed perfectly at Underdown when planted in this manner. Of *Saxifrages*, many varieties of the mossy and encrusted sections are grown. Amongst those in bloom, *S. Cotyledon*, *S. lantoscana*, *S. Macnabiana*, *S. pyramidalis*,

Saxifrages at Underdown, Ledbury. From a photograph by Mr. S. W. Fitz-herbert, Torquay.

Honière, with a stem circumference of 7 inches, having a head 8 feet in diameter. Paul's Carmine Pillar, climbing over a trellised arch, was in full bloom, and presented, with its numerous large single blossoms, a most lovely sight. The Austrian Briers, both copper and yellow, allowed to grow at will, sent tall flower-laden shoots 7 feet and more into the air, and a plant of *Clematis montana* garlanded the dark boughs of a great Yew with ivory-white stars.

The rock garden, which is singularly well furnished and shows but few traces of the fragments of rock with which it has been fashioned beneath the luxuriance of flower and leafage, contains many rare and charming plants. *Achillea argentea*, with its white flower-heads and silvery foliage, formed an exquisite contrast to the blue of *Lithospermum graminifolium*,

more robust-growing *A. grandiflora* was also flowering well. *Aster alpinus* presented a spot of soft colour with its lavender-purple blossoms, and *Astragalus hypoglottis alba* was producing its Vetch-like blooms. *Bellis rotundifolia corulcescens*, which was in flower, reproduces itself freely from seed, and *Bellis sylvestris* was bright with crimson blossoms. *Cardamine asarifolia* was in bloom, as was *Coronilla iberica*, and *Crepis sibirica*, which is rather common place in appearance, notwithstanding the commendation it has of late been accorded, was bearing its bright yellow flowers. *Cypripedium spectabile* was growing strongly, and appeared exceptionally vigorous, while of the *Dianthus* family, *D. alpinus*, *D. cassius*, *D. deltoides*, *D. petraeus*, and *D. plumosus* were in flower, as was a striking dwarf hybrid raised from seed by Mr.

and *S. Wallacci* were notable. Large patches of *Silene alpina* had a pretty effect. *Sisyrinchium bermudianum* and *S. angustifolium* were in flower, as was *Scutellaria alpina*, which seeds itself freely; while of *Veronicas*, *V. Guthriana*, *V. Haasti*, *V. Hulkeana*, *V. pinguifolia*, *V. prostrata* and *V. saxatilis* were adding their tints to the display.

In the borders assigned to the general collection of herbaceous plants much floral beauty was also present. The hybrid *Aquilegias*, with their long-spurred blossoms of suavely graduated tints, purple, blue, lavender, saffron, sulphur and white, the large-flowered *Anemone italica* with its bright blue, *Asphodels* that reared their white spear-heads in groups against an evergreen background, and *Camassias*, belonging to the same order, filled important

places in the decorative scheme. The *Cistuses* in themselves were a host, being represented by *C. albidus*, *C. creticus*, *C. crispus*, *C. florentinus*, *C. laurifolius*, *C. purpureus*, and *C. salvifolius*, some of them being fine bushes smothered in blossom. A pretty variety of *Campanula glomerata* named *pallida* was in flower, and the bright orange of *Cheiranthus Marshalli* was a most effective note of colour in the borders, where *Chrysogonum virginianum* was also in bloom, as was *Coronilla glauca*, which in this garden lives through the winter in the open. The tall *Doronicums* were golden with blossom, and many bushes of *Eurybia Gunnii* were white as snowdrifts, not a particle of green being visible to break the sheet of bloom. *Erigeron bellidifolius* was flowering, and *Henchera sanguinea* was bearing its coral-red bloom-spikes. Clumps of *Inula glandulosa* were remarkably strong, some being 3 feet in height and blossoming profusely. The Flag Irises of many varieties were producing their showy flowers, and *Iris sibirica* had also expanded its blossoms. Lilies are grown in tubs, sunk level with the surface of the border, in order to prevent the soil in which they are grown being impoverished by the roots of the trees that surround the beds dedicated to their use. They appear well suited by this arrangement, and give promise of a satisfactory blooming period. The larger form of St. Bruno's Lily (*Anthericum liliastrum majus*) was in flower, as was the bright *Lychnis Viscaria splendens* fl.-pl. The tall *Linaria macedonica*, with light yellow blossoms, is a handsome though seldom-seen plant for the wild garden or back of herbaceous borders. *Melittis melissophyllum* and *M. m. grandiflorum* were also in bloom, as were *Mertensia sibirica* and *M. virginica*. *Narcissi* are naturalised by the thousand in the grass and are also grown in beds, some of these being surfaced with mossy Saxifrage. This plan is, to all appearance, eminently successful, as the leafage of the *Narcissi* appeared strong and healthy, while it possesses the æsthetic advantage of presenting the Daffodils rising from a green carpeting instead of from the bare earth. The white-flowered *Orobis sylvestris* had a pretty effect, others of the same family in bloom being *O. aurantius*, *O. niger*, and *O. lathyroides*. *Phyteumas*, *Polemoniums*, and *Pyrethrum* were also flowering; the giant Oriental Poppy lit up the borders with its blaze of vermilion, and *Papaver pilosum* spread its fragile blooms of apricot-pink, while the double white Rockets filled the air with fragrance, and their single sisters stood out in high relief against the dark Hollies. A splendid plant of the Californian Bush Poppy (*Romneya Coulteri*) looked the very picture of health, and gave evidence of a bountiful supply of its scented white crêpe-like blooms during the summer. *Salvia pratensis* was in bloom, and a long group of finely-grown Solomon's Seal, arching the white-belled stems beneath the trees, made a reposeful picture. Of Starworts there is a collection of sixty or seventy varieties, many of the best having been raised from seed by Mr. Bickham. *Thalictrum aquilegifolium* was in full flower, the pure white and lavender varieties being represented as well as the ordinary parchment-white type. Globe Flowers (*Trollius*) in variety were also in bloom, as were *Veronica gentianoides* and *Verbascum phœniceum* in many colours, one of a purple-maroon shade being very striking.

In a sheltered corner a Fern garden had been fashioned, in which the best forms of English Ferns, as well as North American, Japanese, and New Zealand species, were flourishing. The Oak Fern was growing thickly, and *Adiantum pedatum* had thrown up vigorous fronds,

while in one portion hardy Orchises were flowering. S. W. F.

THE CLEMATISES.

(Continued from page 127.)

SECTION IV.—AZUREÆ.*

THE *C. azurea* are of Japanese origin, and were introduced into Europe by Siebold along with *C. florida bicolor*. During the year 1838 the type made its first appearance in gardens. The forms of *C. azurea* are all climbers, frequently of small stature, but attaining possibly a height of 2½ yards. Their leaves are fairly large, borne upon long, tendril-like stalks, smooth and green on the upper, and lighter green on the under side. The single flowers are borne upon peduncles of greater length than the leaves; they have six to eight large sepals, and are 4 inches to 6 inches in diameter. The blooming time is April and May. The facility with which the forms of *C. azurea* ripen their seed renders them useful for hybridising, in which horticulturists have vied with each other, more especially within the last twenty-five years. The first forms of *C. azurea* I cultivated—now forty years ago—were all of the azure-blue, purple, or white kinds. They comprised the type *C. azurea*, with its original varieties, for the most part introduced from Japan, *C. monstrosa*, *C. Fortunei*, and *C. Standishi*.

C. AZUREA (Hort.), *C. cœrulea* (Hort. Belg.), *C. azurea grandiflora* (Ann. de Fl. et Pom.), *C. patens*.—This fine species is difficult to recognise now-a-days in the midst of the numerous hybrids. The flowers, displayed and revolved, are of a purple-rose colour of some depth, changing to a lilac-rose colour, and later on to azure-blue. The type varieties of *C. azurea*, which I have cultivated since their introduction, are purple or white. Each group is distinguished by the colour of the stamens, which is either brown or yellow. To the first group belong the following varieties:—

C. SOPHIA.—A very distinct variety, introduced by Siebold. The flowers are larger than in the species, purple, quickly changing to white, very slightly tinged with rose.

C. SOPHIA FLORE-PLENO.—A double-flowered variety, regular in bloom, also of Japanese origin. The second group comprises *C. Helena*, with white flowers and yellow anthers, and *C. Louisa*, with white flowers and brown anthers.

C. AZUREA MONSTROSA.—In this variety, introduced from Japan by Siebold, the sepals, which are straight, irregular and limp, are at first greenish, changing to white, and sometimes even to rose. The result is a flower of long duration, which owes its name to the change which the sepals undergo.

C. FORTUNEI (Moore).—Fortune's Clematis was first introduced from Japan into England by Robert Fortune about 1860, and passed into the hands of Mr. Standish. It is a handsome, double, blue flower of taller growth than the preceding ones, being sometimes 4 yards to 5 yards in height. The flowers are of a handsome white, and continue long in good condition.

C. STANDISHI.—This ought not to be classed with the forms of *florida*, as it often is, its proper place being among the forms of *C. azurea*. It is a variety or a species which, like Fortune's Clematis, was directly introduced into England. The plant is distinct through its foliage, which is that of *C. florida*, but the flowers, which are well formed and graceful, are those of *C. azurea*, and of a fine satiny azure colour. *C. Standishi* is of no great height, and I believe it to be tender.

Such being the type, species and varieties of the *azurea* group, I have now to place, according to their rank, the numerous hybrids, which are often very brilliant, though some of them

* I prefer the name *azurea* to that of *patens*; it is more frequently met with in practical horticulture, and is easier to render in the plural than *patens*.

not equal to the species. It is important to remark that of all the Clematises the *azurea* are the most likely to give us double flowers from seed, a fact which has been proved in the case of *C. Sophia* fl.-pl., *monstrosa* and *Fortunei*, which were originally introduced in this form. Horticulturists, judging from their knowledge of the old Indian *Atragene* (*C. florida plena*), are frequently disposed erroneously to place in the *floridæ* group certain double-flowered hybrids which are in reality *azurea*, like the English hybrid *Countess of Lovelace* and the *Lucie Lemoine* of M. Victor Lemoine, of Nancy, which I see classed with *C. florida* in the enumeration of the numerous Clematises exhibited at the Lyons exhibition in 1892.*—Dr. JULES DE BELE, in *Bulletin d'Horticulture de la Sarthe*.

(To be continued.)

TUFTED PANSIES FOR DINNER-TABLE DECORATIONS.

VERY rarely does one see Tufted Pansies used for dinner-table decoration, and yet there are few flowers to compare with them for use in this way. Doubtless the short stems and also their liability to wither early are in a measure accountable for this, more particularly if the orthodox epergnes and similar large receptacles be used. Shallow bowls are admirably adapted for use in this way, so, too, are some of the dainty little hand-baskets now frequently met with. These latter are usually fitted with shallow metal or earthenware basins, and if these be filled with green Moss and a further supply of water be added, the blossoms of the Tufted Pansy may be easily and expeditiously arranged. There need never be any regular and uniform method of their disposition on the table. For a small dinner-table I have seen a bowl placed in the centre, and a small hand-basket stood at either end and three or four specimen glasses of varying heights on either side have completed a neat and pleasing display, not overdone, as many dinner-table decorations often are. Arranging the blooms is a very simple matter, and this may be carried out without the aid of wire supports. If each receptacle be partially filled with green Moss, as previously suggested, the flower-stem may be stuck into this, and the resistance thus afforded is quite sufficient to keep the blossoms in any desired position. Sufficient embellishment to the display may be obtained by the use of Pansy foliage, and as this is easily obtainable during the summer months, it should be in frequent request. It is better to place the foliage in the utensils first, as the flowers may be more effectively arranged in this way. Some persons may prefer to use other foliage. If such be the case, the bright green fronds of the *Davallia* and Maiden-hair Fern in variety, but of the lightest shade of green, are very useful. Some of the rayless Tufted Pansies are seen to great advantage when used for this purpose, and a particularly pleasing picture was once seen in the association of a beautiful yellow and a cream-coloured variety. The yellow flowers predominated, and a blossom or two of the cream-coloured sort was quite sufficient to secure the necessary effect. Another pretty arrangement would be that of different shades of yellow. In this way primrose, pale yellow, clear yellow, rich and deep yellow flowers would each enrich the other. The contrast of the pale green foliage with these flowers would also be most effective. I have seen an arrangement of yellow Pansies in which a few blooms of a fine blue sort were associated, and this under artificial light was specially good. Overhanging the various receptacles were beautiful pieces of *Selaginella Kraussiana*, this with its peculiar tints being most effective.

The many colours in which the Tufted Pansy may now be obtained give one a splendid range

* *Revue Horticole*, 1892, p. 205.

from which to make a selection. One fact which is of paramount importance is that the flowers of the Tufted Pansy may be had in most gardens from April until October, so that during this somewhat lengthy period it would be an easy matter to arrange an occasional display of their blossoms on the dinner-table. It is important to remember that those varieties producing flowers on long footstalks are the most acceptable for this purpose, and as there is a goodly number of these no difficulty would be experienced. Selfs, too, are better for work of this kind.

D. B. CRANE.

Milla biflora.—What a lovely plant this is when seen in good condition and flowering freely! Much of this, of course, is due to size and strength of individual bulbs, and when these are of large size good results may naturally be expected to follow. Some good examples were contained in Messrs. Wallace's group of bulbous things at the Drill Hall on Tuesday last, and quite recently at Kew we noted splendid examples among the

ties in commerce that produce perfect form and pods. Let us have a complete list of these, so that all the world may know what to purchase and what to grow. The National Carnation Society should give a lead in this direction.—A. D.

Water Lilies and their enemies.—On looking further into the matter of the destruction of the flowers of the rarer and newer Water Lilies, we find that, though the water rat is the most active and numerous of the enemies of the Water Lily, the barn rat must also count as one; and perhaps as bad as either of them is the water hen. In a rich tuft of the tall Reed Grass we found two nests of water rats built of the petals and the ruins, in various ways, of about 100 flowers and buds, mostly of the large white American Water Lily (*N. tuberosa*), and twenty-nine flowers of the beautiful *N. Marliacea rosea* were found in one tuft of Rushes. Where no notice at all was taken of these enemies, no flowers or buds were visible on the plants, so that one might assume that the plants were worthless. Free of such

when the bulbs are planted in a deep sandy loam and in a position partially shaded from the full rays of the sun. The roots are few in number, but particularly stout and of a deep descending nature. The flowers vary a good deal in tint, and still more in the size and number of the spots. The showiest form is that in which the ground colour is a rich reddish orange, with comparatively large spots. To this the varietal name of *magnificum* is sometimes applied. The Lily which is often assigned specific rank under the name of *L. Bloomerianum* is but a form of *L. Humboldti*, in which the dark spots are surrounded by a deeper tint than the rest of the flower. Another North American Lily that is rarely seen in good condition in this country is *L. Washingtonianum*, a pretty and distinct species, but of very little value here. The stock of this Lily is usually kept up by importations from North America, but as a rule they quickly deteriorate. The blossoms of this are white when first expanded, but afterwards become tinged with purple. A deeper tinted form, known at one time as *L. Washingtonianum purpureum*, but which is now assigned specific rank under the name of *L. rubescens*, is no more amenable to cultivation than *L. Washingtonianum* itself.—H. P.

NOTES ON HARDY PLANTS.

Potentilla Thurberi.—The rich crimson flowers of this species of *Potentilla* have a fragrance exactly resembling that of a Peach. This must be a good feature to commend an uncommon flower, but it is not the only one worth special note in the present plant. The colour is an unusual one, maroon-crimson, and the central part of the same colour. The size of the flowers, which are numerous, is a little bigger than a shilling. The habit of the plant is nearly like that of the florists' sorts, but its parts are rather less. It is a very hardy American species.

Kniphofia foliosa.—This is distinct in every way, especially in its period of flowering, which is given in books as August, but I know of some large open-air specimens that came into bloom in June this year and are now seeding. This is an Abyssinian plant, so it may be queried how an open-ground plant could winter safely and get into flower so soon as June. Not only, however, is this the fact, but the garden is in Yorkshire, near the moors, and the plants are in the natural heavy clay soil, and for many years they have stood where I saw them. As winter sets in they are surrounded with dry litter for nearly their whole height, and this is simply removed after the severe late frosts. If seen out of flower the plants suggest old stools of the more glaucous *Yuccas*, or even some *Agaves*, so short, thick, and broad are the leaves, which are very wide at the base, and they reflex in a symmetrical manner. The flowers are exceeding large, both in the pips and spikes, and of a high and beautiful blend of colours of scarlet and yellow. The habit, too, is just as distinct as its other features, somewhat forked in the lower woody part; and from these offset branches the formal tufts of glaucous foliage afford a unique and tropical effect, to get which no care can be too much, especially as I was assured that the plant had proved hardy for years.

Inula oculus Christi.—This is a beautiful form at all stages, from the bud to fully expanded heads. I know there is some confusion about these large *Inulas*, but I think I have this quite right. Its merits are that it links the periods of the earlier kinds, such as *glandulosa*, *Hookeri*, and *grandiflora*, coming after these have done and lasting until the perennial *Sunflowers* come. In the bud state it is really attractive. The big buds are almost flat, and merge into a big bract-like set of leaves of rosette form, and for days before they open they show a button-like centre of a rich mahogany red. Newly opened, they have their ray-florets charmingly fringed, and when fully open the heads are rather less than those of *glandulosa*, flat, rigid, and glistening. The height of the flower-stems is 18 inches and

View in the rock garden at Underdown, Ledbury. From a photograph by Mr. S. W. Fitz-herbert.

bulbous things mostly from the Cape. In some of these the tube was fully 9 inches long and blossoms upwards of 3 inches across; the flowers, too, are very pure. Some stems we noted had produced three flowers each. For pot culture it is excellent, as special attention may be then given it.

Split-podded Carnations.—I should like to see established a sort of Carnation *ind. x capri-gatorius*, into which should be put all varieties that have split pods. Without doubt these detract very largely indeed from the merits of one of the most beautiful and popular of garden flowers. If the gardening public would ruthlessly resolve to both weed out and destroy all varieties subject to pod-splitting, and also not to purchase any others that were so, we should soon get rid of these very annoying varieties. Next to finding a batch of plants raised with the greatest care bearing single flowers, no annoyance can be greater than to find them producing large double flowers all loose and in rags. We have many fine varie-

ties, they flower as freely as any plants, and even in distant effect are very charming. Though the destruction in this case is apparently confined to the flowers, it does not follow that weak and young plants of the rarer kinds would not be destroyed by the same means, and, in fact, we have lost a good many. These enemies occur most, as in this case, where the supply of water is from streamlets inhabited by rats and water hens, and the same troubles are not present in small ponds fed by springs or pipes.—Field.

Lilium Humboldti.—If it could only be induced to thrive, this Lily would certainly take high rank. Large bulbs of *Humboldti's* Lily are often sent to this country from their Californian home, but many of them fail to become established, and as a rule very little is seen of them above ground the first season after planting. They are said in a native state to always grow on well-drained soil, and usually where the subsoil is rocky and the upper soil is clayey or volcanic. In this country the greatest success is attained

the habit of the plant vigorous. I have had another plant under the name with quite small flowers, the plant less in all its parts, and more downy—almost grey. Anyhow, this plant is not common, and, what is more, it is a beautiful and useful border plant that may claim a place among the best herbaceous things. I lost it once by trying to propagate it in the teeth of winter. I now transplant as soon as flowering is over, or leave it till March.

The *Dentarias* are now all merged in the genus *Cardamine*. Still, many of us for a long time will more easily recall those pleasing and interesting plants by their older names of *Dentaria*. I merely mention the above fact of change of nomenclature because I know there has already with some GARDEN readers been experienced some confusion. See *Kew List, Cardamine*, pp. 95, 96. What I wish more particularly to speak of is that now is the best time to either plant, transplant, or propagate these curiously-rooted species. Some of them—most—will now be leafless. Still, their rhizomes, like most bulbs, are active in the autumn, and these become clothed with the fine fibres peculiar to their scaled and knotted root-stocks. For half-shady places the whole group is useful, and, further, it suits these plants to have given them a place where they may remain for many years. The early-flowering *D. digitata* is typical in this respect, and I can refer to a group in my own garden which has never been lifted for eighteen years.

Campanula Vidalli.—My object in this note is to learn if possible if anyone has tried this plant for hardiness, and if so, to what extent and in what sort of climate. I have grown it for three years and now have but one plant in flower for the first time. It takes my fancy immensely if only one could grow it out of doors. The rugged and fruticose habit, the peculiar and thick shining foliage and the long spikes with big white bell flowers of distinct shape (contracted midway down the tubes) are all uncommon features. I am inclined to believe the plant or shrub is almost hardy, as a few cuttings I put out of doors last year were left out most of the winter.

Silene Elizabethæ is a dwarf plant, producing in July and August large flowers of an intense rosy crimson colour. No sooner do the flowers appear than this *Catchfly* of the Tyrolean mountains asserts itself as the queen of the genus. A good patch arrests attention long before one reaches it. It has, however, the reputation of being hard to cultivate or even "miffy," and I think its requirements are special—light and moist soil and an east or west aspect are the chief conditions which I have imagined it to like, and going on this dictum I get good growth and big clean flowers. Slugs, however, are its most deadly enemy in an English garden. I keep them off it by means of frequent pepperings of dry sand all around.

Campanula Tommasiniana is a variety (Koch's) of *C. Waldsteiniana*. It is not enough known, or at least not enough grown. It can be distinguished from the type by the flowers being in racemose spikelets, whereas those of the type are tiny panicles, and further the flowers are long and tubular compared with the cup-shaped bells of *C. Waldsteiniana*. When not in flower it is hard to tell the one from the other. Both are 4 inches to 5 inches high, most fragile and delicately beautiful. Packed into a moist chink where there is a seam of rich leaf-mould is the place for them. J. Wood.

Woodville, Kirkstall.

Continental Carnations.—The varieties sold commonly by the trade as French or German and, of course, of foreign production, are very charming things to furnish cut bloom, the bulk being so much better than the flowers of the Marguerite strain, but they do not bloom so late or over so long a season. To florists anxious to obtain fine flowers from seedlings, these continental varieties would be disappointing, as few flowers are of sufficient size or merit to compare

with the good flowers obtained from home sown seed. But we can obtain seed of the best strains at home only under glass, as only in the very hottest and driest weather will good double flowers become fertile. Under glass nearly all flowers have to be artificially fertilised, and no one getting a good strain should complain of the price of such seed. Even twenty good varieties out of one hundred seedlings is not a bad result. The continental varieties, however, make but little grass. They bloom profusely, and in that respect are admirable to grow for the furnishing of flowers for cutting. All the flowers are sweet-scented. It is well to raise them from seed sown outdoors early in May—and robust plants will result—to go out into beds specially for cutting from in the autumn. The colours found in the flowers are very varied and beautiful. The stems are stiff and erect, never falling about. To secure such habit on many of our best varieties would be great gain. A grower of singles or "jacks" for the hawkers, having a quantity of these foreign doubles, endeavoured to induce the hawkers to prefer them to the singles, but they would not look at them because the leafage was so narrow.—A. D.

Mesembryanthemums in the garden.—A Noon Flower in bloom in my greenhouse to-day leads one to think that someone who has had experience in growing these out of doors would do a service to many by pointing out the hardiest of the species. My own experience of the *Mesembryanthemum* is but scant, and is not, I fear, very encouraging. The annual species require no comment beyond saying that they might with advantage be more widely grown than they are. The curious gnarled-looking *M. uncinatum* of Haworth I grew for some five or six years until it became a fair-sized bush. It never flowered, however, and was more thought of as a curiosity than as an object of beauty. It eventually succumbed one hard winter, but I am disposed to think that it might have lived until now had it been planted in a more sheltered situation. About ten years ago a firm making a speciality of new and rare plants offered collections of seeds of the perennial *Mesembryanthemum*, recommending them for bedding and also for planting permanently in dry places. They come readily from seed, and from seed obtained from the firm in question several species were raised and the young plants put out. They did not bloom that season, and were left out during winter to take their chances of the weather. That winter was a mild one, and a number of plants survived. They did not flower the following summer, and were left to their fate, with the not unexpected result that next winter carried them off. While at Mount Usher, Co. Wicklow, in June, I saw several Noon Flowers on the walls and rockwork. They seem hardy there, but Mr. George Walpole told me that they do not do well. This did not surprise me, as the situation, although very favourable to many flowers, would not, I think, suit succulents. There ought, however, to be a good many gardens where these *Mesembryanthemums* should grow, and any who have experimented with them would confer a favour by giving us their experience.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

NOTES AND QUESTIONS.—FLOWER.

Veronica virginica.—For the background in the border this is by no means to be ignored; indeed, the height to which it attains (nearly 5 feet) is useful for the position indicated. It is of erect growth and bears profusely a good number of white spikes of flowers.

Erodium guttatum.—This pretty plant has been flowering freely for some weeks past, and promises to continue for some time. The flower is larger than in many kinds and pure white, save for a conspicuous dark blotch that renders it unique. The plant is of easy culture in sandy loam that is also well drained.

Michauxia campanuloides.—After repeated trials of this in the open ground it must be admitted

as of little value as a permanent subject, and when grown under glass care should be taken that it be grown on a shelf near the glass where air is constantly being admitted. Grown on into large plants in pots in a cool house, it may be transferred to the open in May to later expand its quaint and large white blossoms.

Crocus vallicolus.—The interesting article on autumn Crocuses by Rev. C. Wolley-Dod contains a reference to this pretty early autumn Crocus. It appears to succeed better at Edge Hall than it does here. A couple of corms received several years ago never produced a flower and failed to increase, eventually being lost. One procured three years ago flowered the first season, but has not done so since. I have been disappointed also with the flimsiness of the segments and their want of substance.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Carnation Isinglass.—This was raised by Mr. C. Salter, Mr. T. B. Haywood's gardener, at Reigate, and has recently received an award of merit at the Drill Hall. It is a great merit of this variety that whilst the blooms are so fine, having broad flat petals and smooth edges, not one flower splits the calyx. Then the variety has the true base growth or border habit outdoors, and it is very robust. I have seen several scores of plants growing in the open at Reigate where the habit is all that can be desired. It is a very profuse bloomer.—A. D.

Mecopopsis Wallichii.—The blue Poppy of the Himalayas is now finely in flower, and constitutes one of the best bits of colour in the garden. It is less fine, however, in point of spike than is often seen, a fact which is doubtless due to the long spell of dry weather, for, notwithstanding frequent heavy watering at the root, it is not possible to compensate the exceedingly arid nature of the atmosphere at such a time and which tells heavily on many like things. Seedlings of this plant raised this year should be planted without any further delay in order to secure fine rosettes for flowering next summer.

KITCHEN GARDEN.

CULTIVATION OF EARLY WHITE ONIONS.

Now is the time to sow Onions for gathering in May and onwards to succeed the keeping Onions, stores of which will then have been exhausted. By sowing the Onion in August we make sure of a supply from May to July. An important point is the choice of varieties and seeds. There are, in fact, a number of varieties of white early Onions in existence, but from our point of view at present the thing is to get early kinds. This object is fulfilled by growing the following, classed in the order of their ripening: *De Barletta* (very early), *à la Reine* (very early), *de Nocera* (very early), *de Vaugirard* (very early), *de Paris* (early). The three first are of Italian origin, and coming as they do from a much warmer country than ours the effects of our hard winters are very perceptible in the plants. It is not so with Onions of *Paris* and *de Vaugirard*, which, though doubtless originating from Italian stocks, have from long cultivation become hardier. They have long been grown by the *Paris* market gardeners. It is important, therefore, to know if the seeds were gathered in a warmer country than that in which the sowings take place, as if so, there will be reason to doubt the hardiness of the seedlings. On this ground *O. de Paris* from seed obtained in Italy will be less hardy than *O. de Nocera* would be if obtained from seed grown in *Paris*. This being so, I should recommend the Italian varieties for the west of France and for climates milder than that of *Paris*, reserving the others for the north, the east, and the centre of France. The Italian varieties may, however, be grown with the assistance of frames and boxes to shelter them in winter.

The Onion likes a soil which has had no manure for some time and been made firm

before sowing. In sowing at the present time choose a sheltered piece of ground, along a wall for example, and sow thickly. A small square is generally sufficient for sowing, as the plants will be planted out later on, and if boxes are used they can be stood in frames. This is the right way in the north and for delicate varieties. Choice can be made between planting out before or after winter. In the west of France planting out is done before winter, but in the north it is delayed until February or March. In Paris it may be done before or after winter, but in the former case it should take place before the frosts come, so that the Onions may have had time to take root. Planted in autumn they are more subject to frost if they are not well rooted. It is less easy also to protect them unless they are planted out under frames. I therefore advise in cold districts that the planting out should be done in spring, at the end of February or March, in the following manner: Choose a well-exposed situation; if desired, Radishes may be sown there for consumption twenty days afterwards. If so, rake over the seed and then plant the Onions with always 4 inches of space between. Before planting remove the extremities of the leaves and roots. The bulbs are generally fit for use from May, more or less according to the varieties classed above. They are gathered as required; those left in the ground ripen in July, but do not keep through the winter. —JULES RUDOLPH, in *Le Jardin*.

Cabbage and Cabbage sprouts.—Much has lately been said in favour of Cabbage sprouts. My practice for many years has been to plant Ellam's Early in autumn for spring use. This I have found the best early kind. When these are cut the ground is cleared and Celery trenches dug. The second crop of Cabbage is planted in early spring from autumn-sown seed. After the heads of this crop are cut the ground between the plants is cleared of weeds, all the old leaves that are green being left on the stumps. These encourage sprout growth and also shade the ground and prevent loss of moisture. A good soaking of liquid manure from the farmyard is all that is required to give a heavy crop of sprouts and small Cabbage in autumn and winter, these being much more prized than Savoy. —W. O., *Fota*.

New Pea Acme.—This is the result of crossing Veitch's Early with Stratagem, and by getting the splendid quality of the latter with the earliness of the former a new variety of special merit has been produced, and one that will be valuable for early supplies. I think Acme will be a popular early variety. It is a 3-foot Pea with a strong haulm and a very full pod containing six to eight Peas, and its earliness with grand cropping qualities will make it most valuable for forcing and early sowing. Stratagem is not one of the best for heavy soil if sown early, as the seed germinates slowly, but this variety largely partakes of the hardness of Veitch's Early, and was one out of very few that did well at the Royal Horticultural Society's Chiswick Gardens, receiving an award. Being a continuous cropper, it will be of great value for early supplies either in frames or the open ground. —G. WYTHES.

Capsicum Erect Fruiting.—This makes a very ornamental plant, and where the pods are cured for it is as profitable a variety as any. The fruits set very freely, are erect, tapering to a point and very bright red in colour. The seed should be sown in March or April if the plants are required for winter decoration and must be kept growing and the flowers pinched out until the final potting. Sow with a dibber about an inch apart on carefully prepared seed pans or pots, as the seedlings transplant badly if the seed is sown thickly. When in the rough leaf prick them off around the edge of pots or into pans and pot into 3-inch pots when necessary. No coddling

must be allowed, growing the plants in a light and airy greenhouse or frame from the first. Repot into 6-inch pots in a light and not too rich soil made firm. No stopping is required, the plants branching naturally. They must be fumigated once or twice during the growing season, as they are singularly liable to the attacks of green fly, and occasional syringing after the fruits are set is helpful. Good well-fruited plants look very pretty under artificial light.

Autumn-sown Onions.—I never remember a season when I had better Onions from seed sown last August. No matter what variety, the bulbs are grand, and this with only ordinary culture. The same remarks apply in other localities, as I was recently in the midland counties and the western part of the country and I saw some splendid crops. It is usually a fair test of the season when the cottagers and allotment holders stage this vegetable well. A few weeks ago at Ealing show there was a grand array of autumn-sown roots all so good and in such quantity that it was difficult to make the awards. "Dorset" (p. 10) complains of the autumn-sown Onions running. Strange to say, I have only had one solitary plant run out of a very large number. On making inquiries I find equally good reports of crops elsewhere. Spring-sown Onions are fairly good, though the crop is not so heavy, as the seed was a long time in germinating this year. Many persons rely on their autumn-sown Onions for their supply in places where the grub attacks those sown in the spring. —G. WYTHES.

Main-crop Peas.—How well these are looking this season, and when compared with last season's crops they form a very striking contrast. So far they have needed no aid in the way of artificial watering, and the haulm is healthy, vigorous, and well clothed with pods in various stages of development. Unless the weather should prove unusually hot within the next few weeks and so hasten growth, the promise of an abundant yield seems likely to be verified. Among sorts that call for special mention as looking particularly promising are Veitch's Main Crop, Mammoth, Triumph, Masterpiece, Champion Marrowfat, and last, but by no means least, that fine old sort Veitch's Perfection. All of these have a dwarf, robust habit of growth, none exceeding 3 feet in height, and they are also excellent croppers. It is yet premature to give any opinion as regards the quality of the first four named, as they are not yet fit for use, but the other two are first-rate in every particular. Autocrat sown at several different dates will succeed the above, and these are also looking extremely satisfactory. Autocrat is a very fine Pea, it and that other excellent sort Sturdy being undoubtedly two of the best kinds we have for late work. They are both of dwarf habit, very prolific, and the quality of the produce is beyond all question first-rate. —A. W.

Digging in green crops.—During the spring of the present year green crops were such a drug on the markets, that one was glad to put them anywhere out of sight, and as the best course at the time open to me was to dig them into the land, I adopted it with several large plots that were being prepared for Potatoes. The plan followed was to open a larger trench than usual, dig the Cabbages or Broccoli up, chop them up with a spade and work them into the bottom of each trench, so that there was a good depth of clean soil above them. The sets were then planted in the usual way. The Potatoes are now ready for lifting, and the heaviest crops are in those plots that had the most green stuff buried in them. I am often surprised to see greenstuff of any kind being carted away from gardens by the scavengers, as anything that will decay in the soil forms food for succeeding crops, and if there is no land available at the time, it can easily be put in the rubbish heap to await a time when it can be utilised. I find a dressing of this kind answers exceedingly well for Potatoes. Some of the best crops, and certainly the brightest tubers, have been grown on land that has not had any strong

manure for years. Very much may be done with ashes, burnt earth, and rubbish-heap refuse towards preparing land for Potatoes. Fresh manure, if it increases weight, also increases the liability to disease and coarse, unshapely tubers. —J. G., *Gosport*.

GLOBE ARTICHOKE.

Will you please give a few practical hints on the culture of Globe Artichokes? Mine planted two years ago seem to grow too luxuriantly; they have huge leaves and are very tall, but the heads are very small and poor eating. Would you advise their being moved to poorer soil? —E. P., *Suisse*.

*** Evidently the Artichokes in question are from a poor stock raised from seed and unselected. Though most seedsmen sell seeds from selected types of the Green Globe and Purple Globe forms, a very large percentage of the produce is worthless, so that a rigid selection must be made of the best types, when the heads form, and all the rest destroyed. This may mean destroying two-thirds or even more of the seedlings. A better way of getting stock is to buy selected crowns of the purple or green forms, as desired, from a reliable source, and then to take good care not to lose the stock again. By no means should the plants be removed to poorer soil, rich soil and free growth being absolutely necessary for the production of good succulent heads, and if strong growing plants, such as "E. P." appears to possess, do not produce good heads, no system of cultivation will make them any better than they are. The cultural details are few, but must not be neglected. Plant in April or early in May in groups of three the strongest crowns which can be procured, the groups to stand at least 4 feet apart. The position should be an open one, and the ground should have been trenched and well manured during the previous winter, and if the soil is inclined to be wet or heavy, some light material such as the ashes from burnt garden rubbish should be added, or if this is not available in quantity, leaf mould and road grit form a good substitute, indeed, any one of the various things which are recommended to assist in making a heavy soil more porous will greatly benefit the Artichokes, and help to prevent their loss during the winter. While the plants are bearing their crop, they enjoy liberal floodings of liquid manure, and under this treatment they flourish and keep on producing successional heads for at least five months of the year. I make it a rule to plant one or two rows every year, as I find that the best crops are given in the second and third seasons, while those newly-planted give a late supply. It is a mistake to allow the old stools to remain in the same spot for many years, as they get weak and overcrowded with shoots. As winter approaches the crowns should be surrounded with dry Bracken, and as this becomes sodden it should be removed and replaced with fresh material. Some recommend coal ashes and others straw as a protection, but I have a decided preference for the Bracken. Wet winters are worse than cold ones for the plants, but they suffer most of all when sharp frosts are alternated frequently by wet thaws, and to avoid total losses of valuable stock in such seasons, I advise that in November some of the strongest crowns should be separated from the stools with a little root attached to each, potted up into 7-inch pots, and wintered in a cold but dry frame, planting them out in May. Old stools may be lifted and divided, the woody portion of the root-stalks should be removed, but each divided piece should have some fibrous roots attached. The Bracken or other protective

material should be removed from the established clumps in spring as soon as the weather becomes genial, and at the same time a good dressing of decayed manure should be lightly pointed in with a garden fork. Should the crowns be much crowded, some of the weaker growths should be removed when they become sufficiently advanced, as this will strengthen those left and tend to the production of first-class heads. For light soils seaweed forms a good manure, and, faling this, light dressings of fish manure or of agricultural salt should be given during the growing season.—J. C. T.

Potatoes.—Should the present dry weather continue through August there will probably be little complaint of disease, as the dryness of the air prevents the fertilisation of the disease spores and renders them comparatively harmless. A very heavy rain with continuous showers would soon be productive of much injury; besides on all breadths that whilst still green have been checked in root-production by dryness of soil, growing out would certainly follow. Much as rain may be desired for other crops, it is doubtful whether, if it came in quantity, more harm than good would not follow to Potatoes. It is not probable that under even the best weather conditions the crop will be a very heavy one, as in many directions the earlier kinds have ripened off, leaving small rather than large tubers. The soil dryness must check the production of large tubers in late varieties, except in cool districts or where the soil is very retentive. But experience has shown that very heavy crops, and especially large tubers, bring little profit to the grower for sale. Price goes down to the lowest point because the markets are glutted, and a big sample dealers will not have at any price. Should the dryness continue, there will be little cause to employ spraying machines and copper sulphate fungicides. Valuable as applications of Bordeaux mixture may be in cold, damp seasons, it is very questionable whether they may not do more harm than good when the air is dry and the sun shines out hotly. The mildness of the past winter was productive of much premature sprouting of the seed tubers, and to that cause is chiefly due the common aspect of breadths, very irregular with many weak plants.—A. D.

Asparagus beds.—It is incomprehensible to me that, with the better knowledge of the requirements of Asparagus that so generally exists, so many cocked-up beds should still be seen. There seems to be an impression in the minds of some growers that so long as depth of soil is obtained that is enough. When beds are but 4 feet wide and have deep trench-like paths or alleys on either side, the surface exposed to the atmosphere is nearly double that found when beds or breadths are on the flat. Still further the rounded form of bed tends to throw off rain, especially when the soil is very dry, and the bulk of it passes away into the alleys, where it is largely lost. Were these trenches filled with decayed manure or leaves, some good might result. But on raised beds plants are invariably unduly crowded to enable the broad, deep alleys to be formed. How much better is it to trench the soil deeply, bury into it a heavy dressing of half-decayed manure, and then plant the Asparagus roots in broad shallow furrows at from 2½ feet to 3 feet apart. Some growers that plant in this way think that a width of 3 feet between the rows is excessive. It may seem so for the first and second years after planting, but later, when plant growths are strong, not an inch too much room is found; indeed, the greater space given per plant is more than repaid by the very fine grass presented for cutting each year. Asparagus breadths are not easily formed, and when done should be well done, that the plants may endure for a long time if desired. All the same he is a wise gardener who raises plants and makes a new breadth every year, as in that way he has a good succession of plants and can always have plenty of old roots to lift for forcing if needed.—A. D.

NOTES AND QUESTIONS.—KITCHEN.

Pea Boston Unrivaled.—In a recent issue "A. W." gives this a good name, and rightly so. I quite agree with all he says respecting it, having grown it now for two years. This year I sowed it at several times. The earliest was fit to pick in the middle of June. It grows with me about 5 feet high, and pods close to the ground. The pods are large, but, unlike those of most of the big-podded kinds, they are not inflated, but filled up.—DORSET.

Tomato disease.—We would be glad if you could give us any information as to the cause of the disease on the Tomato stem we enclose: it was cut off close to the ground. We have lost several plants this year and last, the disease always being about 2 inches to 3 inches above the ground and the stem sometimes quite healthy below. The plants are in the ground and trained up strings in the ordinary way. We sometimes think the strings cause the disease, as on a great many plants a kind of scab forms on the stem below the string all the way up.—CARNEGIE AND BAXTER, *Aggr.*

* * * You state the case very clearly, and I think have formed the correct solution to the problem.

Primula vulgaris.

Straining strings from the stems of plants to wires or other fastenings on the roof in the ordinary way is an unwise practice, and not nearly so economical as many growers consider it to be. I tried it on a large scale for one season, half discontinued it the following year, and at the present have not a single length of string attached to the stem of a Tomato plant. When growing strongly, and more especially during the first few weeks, the bark of the stems is very tender, bruising on the slightest pressure. Straining strings from the stems to the roof means a slight bruise at first and a constant pressure afterwards, and this injury to the bark causes it to become dry and woody, a kind of canker setting up, which spreads completely round the stems, destroying the sap vessels, till at last the channels of supply to the upper portion of the plant are cut completely off and a collapse, gradual, but sure, is the consequence in extreme cases, while many more plants are injured, though not destroyed. Even twisting the stems round the strings is objectionable.

It is a quick way of training, but unless done very carefully the stems may be bruised by the process. My plan, and which I would strongly advise you to adopt, is to early place a 3-foot bamboo to every plant, and in due course to conduct a string from the top joint of the bamboo to wires or nails in the roof. Radia is used for securing the plants to both the stakes and strings. Bamboos unsharpened last for several seasons, and I go to the expense of having stout 8-foot canes for the plants alongside paths, those attached to strings constantly swinging about and getting in the way.—W. I.

GARDEN FLORA.

PLATE 1184.

HARDY PRIMROSES.

(WITH A COLOURED PLATE OF EVELYN ARKWRIGHT.*)

In the very fine sulphur-coloured Primrose Evelyn Arkwright here figured, a genuine Primrose is put into commerce. Not that Primroses are at all new, as we have had many in years past, but constant culture, seeding, and intercrossing have so destroyed the true Primrose habit in them, that now it is difficult to obtain any from seed that do not largely give the Polyanthus habit. Even the more recently introduced blue Primroses, with which Mr. G. F. Wilson's name as the raiser is so closely associated, seem disposed to follow the earlier strains and to become Polyanthuses in the habit of producing flowers in clusters rather than singly.

It is to be hoped that the one now figured will long retain under propagation, either by division or by seed, the true Primrose blooming propensities. Whilst old garden strains gave many years ago some coloured Primroses, it was not until the advent of the rich crimson-flowered auricula-flora, that had thrum eyes and ample pollen, and the large single mauve

pin-eyed form put into commerce some years since by Mr. Turner, of Slough, as *Primula altaica*, which two were intercrossed, that a genuine race of richly-coloured true garden Primroses was introduced. From out of this stock came pure whites, sulphurs, quite as fine as the one under notice; mauves, purples, crimines, reds, and crimsons, and for some years those through seed, which they gave pretty freely, reproduced their kind. But, being grown close to richly coloured Polyanthuses, and apparently developing the innate tendency of all Primroses under cultivation to become of Polyanthus form, so many eventually reproduced, though still in beautiful colours and fine flowers, the cluster on elongated stems, that the old and

* Drawn for THE GARDEN by H. G. Moon from flowers sent by Mr. J. H. Arkwright, Hampton Court, Leominster. Lithographed and printed by J. L. Goffart.

PLANT SPECIES

charming Primrose habit largely disappeared. The result is that now, with the exception of the blue strain, it is difficult to get true Primroses from seed. It was always my experience of these flowers that they did originally form so diverse a section, that not only were the flowers all produced on single stems, emanating direct from the roots, but they were invariably pro-

plants form large clumps and bloom profusely.—A. D.

Mr. J. H. Arkwright, Hampton Court, Leominster, who sent us the flowers from which the plate was prepared, sends us the following note regarding this Primrose:

The original stock of this Primrose (found wild in Dinmore Wood, Herefordshire, in 1887) has

obtained in bedding sorts we have advanced a step. The fancier's taste at present is for huge round flowers to torture into sprays with iron fetters. This will speedily prove a mistake, as in many places it is recognised by gardeners that the good qualities of the rayless section is their excellent flowering character. I read your critique with interest, and entirely agree with your opinions. Esthetics are not included in the education of the modern florist. The simpler Tufted Pansies are displayed indoors the better they appear as to their true character.—C. STUART.

THE WEEK'S WORK.

KITCHEN GARDEN.

ARRIERS OF PLANTING. With a genial rainfall any arrears of planting which have been delayed owing to heat and drought may now be made good. I am busy planting Coleworts and late Broccoli, and though full late for the latter, the soil now being in a thoroughly moist condition the growth will be rapid. It has been difficult to make losses good, as with so much heat many plants have become blind. This is more the case with Cauliflowers than any other of the Brassica family, and if there are strong seedlings to fall back upon all losses should be made good. In the case of other plants it may be well to make later plantings if any are at all irregular, as though the produce may be smaller the crop will be a profitable one late in the year. The large Drumhead Savoy planted now for late winter use is far more valuable than earlier produce. It is a good plan to mould up earlier plantings of green vegetables, as these will now be large enough. I have not advised doing the work earlier owing to the soil being so hard and dry. Plants treated as advised will be benefited, as later on in exposed places rough weather often twists them out of position.

CAULIFLOWERS. I am a believer in sowing autumn Cauliflowers for various reasons. Needing a lot of vegetables at most seasons, it is well to have a good supply of all kinds, and to effect this

Primrose Manstead Early White.

anced fully a month earlier than were those of the ordinary Polyanthus strains. It was a very valuable feature, as plants were ordinarily in full bloom in March, whilst the others were never at their best before the end of April.

Some years ago there were numerous varieties certified by the Royal Horticultural Society and put into commerce. These have quite disappeared: indeed, there seem to be few plants endowed with shorter lives than single named Primroses. So far, they will not really reproduce themselves from seed, though many seedlings come very near in form and colour to the parents. But all named varieties can be relied upon to come true only by division, and that process of propagation means annual lifting and dividing, treatment which the Primrose does not like. The most common of the double forms are increased in many parts of the country where hot, dry summers prevail with much difficulty, the plants, both single and double, being so liable to attacks of red spider, which destroys the foliage and so weakens the crowns that they refuse to make new growth. Where that trouble prevails it is needful to water the plants very liberally, especially frequently sprinkling the foliage, and, if practicable, furnishing cool shade.

In the humid atmospheres of Ireland and Scotland all the Primrose tribe usually do well. In the south, when long spells of hot, dry weather prevail, they are difficult to keep fresh and vigorous. There is no better time to sow the seed than in the first week of September, keeping the plants in the seed-beds all the winter, thus having plenty of strong seedlings to put out where to bloom in April whilst the soil is still moist. Such plants become deeply rooted and very strong before the heat of July interposes, and if the leaves suffer somewhat from an attack of red spider, new foliage is strongly thrown up in September or earlier if rains come. Of such plants, whatever may be the quality or character of their flowers, at least many bloom all the winter if that season be an open one, and in the following spring the

kept up its character to the third generation by seed. The first blossoms were almost a perfect circle, with hardly a sign of a dip in the centre of the petal. A good blossom measures $2\frac{1}{4}$ inches in diameter, and in some cases $2\frac{1}{2}$ inches. The plant from which the drawing has been made was grown without any rich food in the soil.

A note from Hillside.—The Tufted Pansies I sent are all seedlings of this year—Argosy, Golden

Bunch Primroses.

Fleece, Ruth, Crème d'Orange, &c. They were raised from seed obtained from one of my dwarf varieties—Coolgardie crossed with pollen from A. J. Rowberry. I think we are now in for an entirely new race in yellows. A. J. Rowberry, although of sprawling habit, is very fine in colour, and no doubt when a race with the same colour is

the autumn-sown plants are very serviceable. On the other hand, where there is ample means to raise plants of the Snowball section early in the year, I do not deprecate this mode of culture, but I fail to get the plants sown early in the year to turn in so early as the autumn-sown. I grow a goodly number for cutting in May and early

June. To get the best results with Cauliflowers, it is well known there must be liberal culture. Few plants of the Brassica family need more food from the time they commence to grow freely, and though the seedlings need the same, it is not necessary to winter the plants in such soil if transplanting is done early. On the other hand, it should be borne in mind that seedlings transplanted, say in February or March, are later than autumn-planted ones, and I therefore advise sowing and planting in their permanent quarters a portion of the plants now, and another lot in the early spring to form a succession. For autumn planting it will be advisable to prepare the land at an early date. My crop will follow early Peas, and a liberal quantity of manure is dug into the soil. I also advise deep culture, as the labour given now will not be lost, the ground when cleared early next summer being in good condition for such as late Carrots, Turnips, or similar crops. Many advise planting in a sheltered position. I have secured the best results on fairly open quarters, as, though the plants may make a poorer growth, they suffer less in severe weather. I still adopt the hand-glass system, as this gives a much earlier return and saves the plants from the cold east winds, which are equally injurious as frost. Those who cannot protect in the way noted may prick out the seedlings rather closely at the foot of a south wall, the chief drawback here being slugs, which do much damage. Plants wintered in frames, unless given full ventilation, get too large and soft, and do not lift well. I prefer those in the open, or a frame may be placed over the seed-bed in the late autumn. As regards varieties, I am very fond of Early Erfurt. Walcheren is also a reliable variety, probably less early than the Erfurt or Early London, but I consider it hardier. In catalogues Walcheren is called a main-crop variety, but I find it an excellent one for autumn sowing.

LATE KALES.—Few vegetables are more useful in March and April than the late Kales. I am aware owing to the late season and drought planting has been deferred, but there should be no further delay, and Kales to make headway need good land. In places where animal manures are scarce, I have found land dressed liberally with a good fertiliser give a good return. My latest Kales are now being planted on land that has produced Strawberries. Rather deep drills were drawn, and a liberal quantity of fertiliser mixed with burnt refuse placed in the drills. This will give the plants the necessary start, and after this a gross growth is not needed. For late supplies, such kinds as Asparagus or Buda, Cotter's Kale, and Ragged Jack are difficult to beat. These are the last to run to seed, and though in severe winters they lose a lot of their autumn growth, early in the year they make new leaves from the base and give a lot of cutting material and of good table quality. Of curled Kales, Read's Hearting is a very reliable variety, very late, and not readily injured by frost. The Arctic Kales are also very hardy and excellent for late supplies.

POTATOES.—Those who cannot find room for very late Potatoes will now be in a position to lift what are termed the mid-season varieties. My best Potato for use from now to December has been Windsor Castle. The crop is not so heavy as in previous years, owing to drought, but there will be no gain in leaving the tubers in the land after this date, as with rain we often get dull weather, with the result disease sets in and the loss is much greater than if the tubers were lifted earlier. With early lifting more care is needed, so that the skins are not injured, but the tubers rarely suffer if given cool storage. Many have to make various shifts and store in places not suitable. Much better results would follow leaving the tubers where grown. I mean placing in clamps and covering with mats and straw for a time, allowing the moisture to escape by occasionally turning over and drying. Tubers needed for seed may be laid on walks or well-drained soil and greened by exposure, turning over frequently,

and when well hardened by exposure, stored in a cool room on shelves or in shallow boxes. Any varieties grown for seed should be examined and lifted if the skins are set, as after a long period of dry weather second growth begins.

TURNIPS.—The land will now be in excellent condition for sowing Turnips. So far the work has been difficult owing to drought, but by sowing now rapid progress will be made. This should be a large sowing for the winter supply. In many places earlier sowings are advocated to get size, but I think a large keeping Turnip is not needed. Far better have roots of a medium size quickly grown than large ones which decay and go hollow. Good soil is needed, and for this I manure land that has borne early Potatoes. For roots to stand the winter where sown I do not give fresh manure, but a good dressing of soot and burnt refuse, and sow the last week in this month or early in September. For winter supplies to store, few varieties are superior to Red Globe, a handsome solid root and of excellent quality. Green Top White is equally good for the store, and not a coarse root. For later sowing the same varieties hold good, but the yellow-fleshed kinds are even more suitable. These winter well in the open, and if grown for their green tops in the spring, give a lot of cutting. Golden Ball and Yellow Malta are also excellent types.

ENDIVE.—Now is a good time to get out seedlings sown for autumn supplies. To get a quick return it will be well to enrich the soil freely, and in lifting to get as many roots as possible, so that the plants are not checked. The advantage of sowing thinly will now be seen, as much better material will be secured for planting. Endive is not used much as a vegetable, but it is well worth growing for that purpose, and the Improved Round-leaved Batavian is the best, this being a hardier variety, and making a large growth in good land. In planting it is well to firm the plants in light soil, and should the weather be dry, give water freely and ample room between the rows. For earliest supplies in the autumn some of the largest plants left in the seed beds will turn in before those that are transplanted, and if sown in drills for early use, it is well to thin freely to give the plants room to develop. A late sowing made now will furnish the supply after Christmas. In favourable winters small plants raised at this date will do fairly well in a sheltered position, say the foot of a south wall.

RADISHES.—Many omit to sow Radishes at this season. I do not advise large roots, neither do I advise one large sowing, but several from now to the end of September. The earlier kinds should be the ones chosen. A north border is best for the August sowings. For winter supplies a different course of culture is advisable, and other varieties may be sown. The China Rose is one of the best for autumn sowing. This is of a bright rose colour, and very sweet in a young state. For storing for latest use the Black Spanish, a large round, very hardy root is good. This may be left in the soil if covered with long litter in severe weather. The winter kinds will be best sown on an open quarter in soil manured for a previous crop. S. M.

FRUITS UNDER GLASS.

PINES.—In well-managed gardens where Pines are still grown the Queen variety should still be the source of supply. Even up to the middle of October it may be depended upon under good management to give the best possible satisfaction. Thence onwards it is safer to depend upon Smooth Cayenne and Charlotte Rothschild, with the Black Jamaica in reserve for the winter season. Those of the Queens which are now swelling should be treated generously as regards water at the roots, and also with respect to atmospheric moisture. The hot weather which we are now experiencing is all in favour of Pine-apples, provided this is duly attended to. Water may be gradually withheld as the Pines colour, but not entirely until about two-thirds advanced in this

respect. A good Pine when well matured should have the stalk fresh and sappy. If shrivelled, something is wrong at the roots and the flavour will not be first-class. There is more risk now of keeping Pines too dry both when swelling and ripening than otherwise, hence the caution now given is needful where the charge is looked after by those not of ripened experience. In order to keep Pines for a time when ripe they can be removed from the fruiting-house or pit and be stood in the fruit room or in a cool and well-ventilatedinery. Look to it, however, that when this is done the plant is quite dry at the roots. Another plan, and a reliable one, too, is to cut the fruits with as long a stem as possible, and then suspend them upside down in the fruit room. Thus, by judicious management, the supply can be regulated fairly well, and the remark so often made that Pines come in all together be refuted. Even if there be a few more on hand than are wanted it is a simple matter to preserve them. Those Smooth Cayennes, or other kinds for later supplies, that are now swelling away after the flowering stage is passed will bear treating liberally. An occasional application of manure-water will assist them greatly twice or so a week for a few weeks to come. During the flowering period guard against wetting the plants overhead. This may be accomplished by a judicious use of the syringe. When it is seen that the crowns are advancing too fast, it will be better to reduce the atmospheric moisture, as it oftentimes encourages this tendency. Too much of the same when no fires are kept in during very hot weather will also foster it. Any stock of plants not yet in their fruiting pots should immediately be attended to. Some suckers may possibly have been taken off in the spring and put into 6-inch and 8-inch pots; these will now be ready to go into fruiting pots. In fact, such should have been the case by June, when in THE GARDEN, p. 544, last vol., potting was alluded to. I know, however, from experience how difficult it is at times to keep abreast of the work with the many and increased demands made upon the resources of the garden. To postpone any potting longer than the present is, however, a risky process, not favourable to the plants certainly. At the same time see to the fermenting material. It is a good time now to thoroughly clean out old beds of tan or leaves with manure as the case may be. Not only is it convenient from the point of clearing off old fruited stools, but also from that of safety to the growing stock, as these may now for a few days be stood in an empty house without any risk being run with them. A thorough clearance once every year is imperative, as a Pine stove or pit is the favourite resort of cockroaches, beetles and crickets, as well as other vermin. If painting has to be done, the advice is, do it at once. Do not delay this important, but to many disagreeable work too long until the wood becomes bare and decay sets in. Whitewash all brickwork, examine the bottom-heat pipes to see that the joints are sound, and make a free use of water as near to boiling point as possible in order to destroy the vermin afore alluded to. Whilst attending to the potting, look after any needful quantity of young suckers where the stock is not up to the requisite number. These can be safely wintered in small pots and may be plunged between the front rows of fruiting plants. Even with the hot weather we are now experiencing, Pines should not be shaded as a rule, but if it is seen that the foliage is looking somewhat yellow, it may be advisable to shade slightly; for this purpose fish netting is quite sufficient.

BANANAS.—Plants now in fruit-bearing condition should be liberally treated at the root, being fed if possible with a top-dressing of cow manure. Even before the fruit shows itself, but when it is seen by the swelling of the stem that such will soon be the case, this should be attended to, because the plants need every possible assistance when developing their large panicles of fruit. By giving them every possible aid, manurial and otherwise, it is possible to lengthen out the fruit

panicle and add to the number of the fingers. No shading is necessary, as the Banana withstands all the sun-heat we get and seems to thrive upon it, especially fruit-bearing plants. A brisk temperature is desirable in order to expedite the ripening. Mine now ranges from 70° as the minimum to 95° as the maximum during hot days, being grown in the same house as late Melons. Look after the younger stock, and keep up the same by taking off more suckers when large enough to secure sufficient roots, and pot on those that are growing freely or plant out as the case may be.

PASSIFLORA EDULIS AND P. QUADRANGULARIS.—Where there is sufficient room or convenience these fruits are well worth attention. They are grown with great success, and are much appreciated too in many establishments. Mr. J. Roberts at Tan-y-bwlch grows *P. edulis* with good results, and Mr. Speed at Penrhyn has also done the same with *P. quadrangularis*. Those who may possibly possess these varieties for their flowers only or as climbers, and true to name, will do well to turn them to account for fruiting also. All that is needed is artificial fertilisation in order to secure a crop, of which a goodly number can soon be had. In some houses a canopy of foliage upon the roof would save outside shading; for such a purpose these *Passifloras* may be utilised. If a bare wall needs covering the same remark applies. Neither of them is fastidious as regards soil. I have found *P. quadrangularis* thrive best in rather poor soil. If encouraged too much with rich material it is disposed to grow too luxuriantly, when it may not flower so well. If plants be taken in hand now, being grown in pots until the spring, they will turn out well.

ORANGES AND THEIR ALLIES.—The forward crop of Oranges should now be ripening (those who have once tasted a well-ripened home grown example will be able to fully appreciate such) in houses that are kept slightly warmed. See that the plants are well supplied with water, and keep them also syringed overhead both for cleanliness and for refreshing the plants. When the foliage is covered with dust or other filth it detracts very much from the appearance of the plants; hence even if time cannot be spared for sponging the leaves separately, it is important to use the syringe frequently. It will be found a good plan to thoroughly wet the plants all over with a solution of soft soap, using the water quite warm, and then as soon as the dirt upon the leaves is well moistened, syringe again with clear water. Two or three such applications will soon brighten up the foliage. Where the shoots still show signs of active growth beyond the green fruits, it will be just as well to stop them and thus encourage the fruit to swell more freely. These remarks apply also to the Lemon and other members of the Citron family, to which, as a whole, more attention should really be given in our gardens than they have for years past been receiving, being of far more importance, adding, as they do, their full quota from a decorative point of view, than the thousands of *Chrysanthemums* now grown just to supply a few mop-headed blooms to each plant, which at the most are of a fugitive character. Pay close attention to any specimen plants that are being made use of outside on terraces and like places, and do not let them be watered in a perfunctory fashion. It is at this season when such plants, by the changing of hands as regards watering, oftentimes come to harm. If it is possible to add a little surface-dressing of decomposed cow manure, do so, and cover the same with fresh soil and press the surface down firmly again. Keep these plants also syringed during hot weather, giving them, in fact, the same attention as if still under glass. These specimen plants may be grown in certain shapes and forms—if so, see to the regulation of the shoots now, rather than in the spring, by pinching and stopping as they may need it.

WATERING OUTSIDE FRUIT CROPS.—The most important item of work just now, where gardens are situated upon soils that are light and gravelly, is that of watering, and even late mulching if

need be, but in any case watering. If trees bearing their full quota of fruit are not kept sufficiently supplied, a premature ripening takes place, which eventually acts prejudicially on the future well-being of the trees themselves. As cases in point, Apples, Pears and Quinces may be quoted. That it pays to water these, even if extra labour be employed to do it, may be proved by anyone who once gives it a trial. Just at the present time all of these fruits need every possible assistance, more especially when we take into consideration the fact that the rainfall of the current year is below the average. On light and well-drained soils this becomes a serious matter during a prolonged drought. No fear need be apprehended that it is now too late to benefit these fruits in this way; hence, if possible, give the matter early attention. HORTUS.

BOOKS.

RIVIERA NATURE NOTES.*

THE authorship of this little book is veiled in anonymity, but it seems to be the notes of some resident in the Riviera on most things that could interest the naturalist or observer in the place as regards its natural vegetation, scenery, gardens, trees native and introduced, aspects of the seasons, fauna, fruits, &c., and even prehistoric man as revealed to us by the very rich cave discoveries of the region. The book is charmingly written, and does not contain a dull line. It is not easy to imagine one more instructive for anyone who thinks of visiting the Riviera to make him acquainted with all the life of the country.

"In the Saxifrage family," the author says (p. 262) "the Maritime Alps possess a plant of great beauty and variety, the famous *S. Florentula*. It was discovered by an Englishman on the verge of the perpetual snow near the highest crests of the mountains. As no further specimen was found by anyone after this for the space of thirty-six years, *S. Florentula* began to be regarded as a mythical plant. But at last the Abbé Montalivo, an enthusiastic botanist of Beaulieu, and other native explorers confirmed the Englishman's discovery, and the plant is now constantly brought in by the chamois hunters, who sell it for half-a-franc. When you are fortunate enough to find a rare plant of which few specimens exist, it is better not to inform the general public of the exact locality, for the less people know about botany the more anxious they will be to tear it up, if it be in the least degree ornamental. If guides and shepherds once find that a plant is worth sixpence, they will make havoc of the species. But *S. Florentula* is safe from extermination, growing, as it often does, on rocks which are inaccessible to human foot. This rare Saxifrage has a peculiarity which is not mentioned in any botanical work, viz., that the terminal flower of each inflorescence has five instead of two carpels."

In the chapter on "Succulent Plants" (p. 100), which starts with the American Aloe, there are two misprints which to students of Dickens read curiously. Thus "Numpkins" for Nupkins, and "Tingle" for Jingle! The immortal Mr. Alfred Jingle!

"There is a popular idea," the author goes on, "that the Agave flowers only at the age of a hundred years, but the real time is given as the fifth to the eighteenth year. It is stated that the plant may be compelled to flower by cutting off the leaves. The Agaves slashed by the sabres of the French troopers in Algeria are said to have flowered prematurely." The mistake of confusing the Agave with the Aloe is one which is constantly made. The *Styrax*, or *Styrax*, flourishes on the western Riviera, and it is well worth while to journey to Hyères in May on purpose to see the bushes in flower. From *Styrax officinalis* incense is obtained. Yet for all the attractions of

* "Riviera Nature Notes." The Labour Press, Limited, Manchester.

its white flowers and yellow stamens and perfumed gum the *Styrax* is not admitted to Riviera gardens. It is different, however, with the white Broom (*Retama*), a bright, cheerful little tree which a Zulu, a Bushi Bazook, or even a Lawyer might stop to admire. The White Broom it was, and not the Juniper, as mis-translated, under which Elijah lay wishing for death in the desert beyond Beersheba. "Through the snowy canopy of the Retem the angel descended to comfort the prophet." Humboldt described the *Retama* as adorning the peak of Teneriffe at an elevation where no other plant can grow. Of the *Acacia*, which is allied to it, over fifty species are cultivated in the Riviera. The pride of the Cannes gardens is *A. dealbata*, which thrives better there than on the calcareous soil of Nice. In Australia, where it is known as the Silver Wattle, it sometimes grows to a height of 150 feet. *Acacia* flowers in immense quantities are sent to all parts of Europe. The gardeners cut off the twigs and force the flower-buds to expand prematurely under steam, and so obtain blooms about a fortnight before the natural time. *A. Farnesiana* is extensively grown for the sake of a perfume extracted from its golden yellow globular flower-heads. The Shittah tree, of which the Tabernacle was constructed, is supposed to be *A. Seigal*, from which gum arabic is obtained, and *A. nilotica*, a thorny *Acacia*, is thought to be the Burning Bush of Moses. Among the peasantry near Nice there is a belief that "you will suffer if you plant a Cypress." Mortola gardens contain an admirable instance of a Cypress avenue. In the Riviera landscape the slender points of the Cypress and the rolling grey-green masses of the Olive offer a striking contrast. Within a drive from Nice there is a spot where Peonies cover the hillside, and when these plants are in flower, in early May, the Riviera has no finer sight to offer. "Almost too abundant to be ornamental, and as a mass of red quite oppressive to the eye," the Peach tree flourishes in some parts of the Riviera. An Iris with almost black flowers is sold in the Nice market in March; the peasants, however, who bring it in refuse to say exactly where they get it from. There are three kinds of wild Tulips, viz., *T. præcox*, *T. Clusiana* and *T. australis*. *Ornithogalum arabicum* is a wild flower, of such striking beauty, even in this land of flowers, that the author at first supposed it to be a truant from the garden.

The book contains also chapters on birds, insects, lizards, peculiar plants, mosquitos, butterflies and moths, wings and stings, summer drought, &c.

WORK ON A KENTISH FRUIT FARM.*

FRUIT farming being now an important industry, any information regarding it will be welcome. The author of these notes, which appeared weekly in calendar form in the *South-Eastern Gazette*, has a wide knowledge of fruit farming as well as vegetable culture, with a grasp of market ways and prices, and his notes were considered so valuable, that Messrs. Bunyard and Co., of Maidstone, have secured the copyright and are issuing them in book form. He begins at Christmas and deals with all the work on a fruit farm from week to week for twelve months, giving at the end of each week the varieties of each fruit that are in season, as also the prices realised for same. Potatoes are also priced week by week. The author's remarks as to growing too many varieties are to the point. He says:—

"Do not plant too many varieties; an acre or two of a good kind is none too much; in fact, some big growers now-a-days have ten acres of one kind. Jumbling up some dozen or twenty sorts is one of the curses of our home-grown fruit. The Americans know far better than we how to enter for British markets, and they restrict themselves to six or eight sorts; whereas, our farmers do not stop at one hundred and six, many

* "A Year's Work on a Kentish Fruit Farm." By a Practical Man. A reprint with a few additional notes of a series of weekly articles in the *South-Eastern Gazette*. Published by G. Bunyard and Co., Royal Nurseries, Maidstone.

of which are absolutely useless for sale. We should stick to standard varieties—we have plenty of them—and avoid as poison everything that has not a name and a position both on the market and among growers.

The information given throughout the book is sound, and will well repay perusal by those engaged in growing fruit for market, and also those who intend to embark in the same. The book is in a handy form, and well printed in double columns. At the end are given a list of the best paying market fruits, as also a very useful table of weights and measures for London markets.

TREES AND SHRUBS.

THE SNOW TREE.

(*OZOTHAMNUS ROSMARINIFOLIUS*.)

BEAUTIFUL as the *Ozothamnus rosmarinifolius* is in the sultry days of June, with its soft spreading branches laden as if with snow, few are aware how decorative it still remains when the summer days of light and warmth are gone and the skies are grey and cold, the trees leafless, and our gardens bereft of colour and fragrance. The sprays of *Ozothamnus rosmarinifolius*, which fill the jar herewith depicted, were cut a year ago, just as the minute flowers attained their perfection and purity, ere dimmed by storm or rain. Hung up by the base, the stems were left for some weeks to dry and stiffen, and ever since have remained erect and fair, drawing, as the flame does the moth, all visitors who enter the room to touch and test the reality of this fair vision of white bloom; and, indeed, to watch the change of visage when I say, "Oh! it was cut last summer," is quite delightful in its scepticism, especially when I add, "and there is no water in the jar!" Small portions of the Snow Tree (a far happier name than its Latin appellation) cut and dried do not give the same fine effect. It is the soft outline of the branches left in their entire length, some 5 feet or more, that produces the symmetry, and makes of the jar and its contents a picture ever restful to the eye. By cutting the large branches at this season, light and air are given to the new growths in the centre, which will be ready to cut in like manner the following summer. A. L. L.

Spiræa arifolia.—This is one of the finest shrubby *Spiræas* grown for grouping on the lawn. Its large white feathery panicles are produced with great freedom, and are most effective at any time, but more especially in the twilight when seen in big masses. Charming as it looks in almost any position, I like it best away from other shrubs and in groups. This year the flowers are late, and only now, at the beginning of August, at their best, and this is a gain, as most other flowering shrubs have now passed their best. A curious thing in connection with a large group of this *Spiræa* is that some of the plants open their flowers weeks in advance of the others, and as this occurs on the same plants year after year and irrespective of position, it leads me to ask whether there are not two varieties, one early and one late-flowering. An excellent use can be made of the sprays by cutting them with the flowers in the bud state and using them for decorating large vases.—J. C. T.

Olearia Haasti.—This, the hardiest of the New Zealand Daisy Trees, is now finely in flower, and blooming as it does during the month of August it is for that reason all the more valuable. The blossoms, too, remain some time in perfection—another desirable feature. It is by no means a graceful subject, forming as it does a dense Box-like bush, thickly clothed with small deep green leaves and completely covered with little Aster-like blossoms. There are many other species

of *Olearia*, several of which are hardy in the west of England and Ireland, where they form handsome flowering shrubs, but in the neighbourhood of London *O. Haasti* is the only one that can be considered hardy. Such species as *O. Gunniana*, *O. dentata*, *O. macrodonta* and *O. stellulata* are more ornamental than *O. Haasti*, but too tender for general culture in this country. *O. Haasti* succeeds better than many subjects in close proximity to the sea. It is easily propagated by cuttings, dibbled into pots of sandy soil, and placed in a cold frame towards the latter part of the summer. The frame should be kept close and shaded from bright sunshine till the cuttings have rooted.—T.

The common white Jessamine.—At this season of the year the common white Jessamine asserts itself as one of the most beautiful of all our hardy climbers, the white highly fragrant blossoms being borne in the greatest profusion, while the dark green prettily divided leaves serve as an admirable setting to the spotless flowers. The Jessamine in question is a universal favourite.

Flowering sprays of *Ozothamnus rosmarinifolius* (the Snow Tree) in a vase. From a photograph sent by Mrs. Lawrenson.

and many a country cottage owes a deal of its beauty to this charming climber. An additional merit possessed by it is the fact that it will succeed in towns better than many other subjects, and not only may flourishing examples be frequently met with in the environs of London, but also in the more populous parts, where smoke and fog play such havoc with all vegetation. The succession of blossoms that is so long maintained is another great point in favour of this charming climber. It has been so long grown in this country that we are almost inclined to look upon it as a native thereof, yet we are told that it was introduced from Persia in 1548. We have now a considerable number of hardy climbers grown either for the sake of their foliage or flowers, and in this latter class in any selection, however rigid it may be, the common white Jessamine must have a place.—H. P.

Cytisus nigricans.—For this Broom can be justly claimed the merit of being the most

continuous blooming of all the shrubby Leguminosæ hardy in our gardens, for it has now been in flower about a couple of months, and the number of unopened buds bids fair to continue the display for some little time yet. It forms a neat growing bush, whose slender branches are clothed with dark green trifoliate leaves, and plentifully sprinkled with spikes of clear yellow flowers, somewhat paler in tint than many of their immediate allies, but withal of a very pleasing shade. The succession of flowers is maintained firstly by the fact that the spikes do not all appear at the same time, and secondly by the circumstance that the flowers at the base of the spike open first and the buds gradually develop, so that one spike will keep up a succession for a long time. Like many others of the Broom family, the roots of this are of such a deep descending nature, that they are less affected by drought than those of many other subjects. *C. nigricans*, which is a native of Central Europe, was introduced as long ago as 1730, and though it can be obtained from most nurseries that keep such things, it is very rarely seen in gardens. Seeds ripen readily, and by this means young plants can be obtained without difficulty.—T.

Eucryphia pinnatifolia.—

It is now over twenty years ago since a coloured plate of this beautiful Chilean shrub appeared in *THE GARDEN*, at which time it was quite a rare plant, and even now though widely distributed it is by no means generally cultivated. The reason appears to be owing to the fact that in many situations it does not thrive as one might wish, and in some districts it is apt to be injured by a very severe winter, while, on the other hand, it will pass unscathed through a degree of cold that would lead one to expect different results. The dark green divided leaves are, if the plant is not in a thriving state, apt to become browned at the edges, thus imparting an unhealthy appearance to the whole specimen. In many districts, however, it thrives, and then the deep-tinted foliage serves admirably at this season as a setting to the pure white *Hypericum*-like blossoms. This *Eucryphia* needs a good loamy soil, lightened by a little peat or well decayed leaf mould, and so situated that though well drained it is not at any time parched up. Cuttings of the half-ripened shoots may be struck if put into pots of sandy soil, but it is not at all an easy subject to root in this way. From its bushy style of growth, however, a few of the lowermost branches may be usually layered without any difficulty.—T.

Double pink Bramble.—Though one member of the genus, *Rubus deliciosus*, ranks high as a spring-flowering shrub, one does not, as a rule, associate the Bramble proper with showy blossoms, yet during the latter part of the summer the double pink form is extremely showy, and that, too, at a period when very few shrubs are in bloom. This double pink Bramble, which is sometimes known as *Rubus fruticosus flore-pleno*, and at others as *R. bellidiflorus*, is in the *Kew* list referred to as a variety (*flore-pleno*) of *R. ulmifolius*. It is of a loose, rambling nature, and if allowed to grow over a few rough sticks it forms a shrub-like mass, which is thickly studded with its pretty pink blossoms. They are very double, consisting as they do of closely packed, narrow petals, a good deal after the manner of

some of the double Daisies; hence the name of *R. bellidiflorus*. This double pink Bramble is referred to by Loudon, so that it is by no means a recent discovery. One feature connected with this Bramble, and a particularly valuable one in the case of shrubs that flower late in the summer, is that it will both hold its own and flower well in comparatively dry sandy soils, conditions such as few other shrubs will thrive under. Like most of the Brambles, this is increased by layering the extreme tips of the shoots, which soon root and produce an independent plant.—H. P.

THE MARKET GARDEN.

CUCUMBER GROWING FOR MARKET.

THE Cucumber was never before grown so largely as now, or even to the same perfection. Whole fields are covered in with glass structures that are nothing more nor less than Cucumber houses specially designed for this work alone. We have to-day Cucumbers as uniform throughout their entire length as a gun-barrel. Firmness of flesh also, which is equivalent to better keeping qualities, is far more apparent than was the case formerly when the old Telegraph was considered everything that was good in such things. No Cucumber, perhaps, has ever had so long a run of favour as this, its one best quality being its free cropping. This was undoubtedly most persistent and continuous. But, like many other popular things, the old Telegraph has no known history. The variety was, however, known to me long before its introduction, when it was grown in a private garden, where it had for years been the only kind grown. The gardener was then very old. He had had the variety many years, grown it and saved seeds, but possessed no knowledge of where he got it from or how he came by it. At the time of which I speak the gardener referred to had been some thirty years in the same garden, and I have it in his own words that he had grown the variety for at least twenty, perhaps twenty-five years, which, together with the time it has been before the public, would make it known and grown within seven miles of London Bridge between fifty and sixty years. Since that time, however, many strains of Telegraph, always "Improved," have appeared, the improvement being in many cases but only in name.

SUITABLE STRUCTURES.—No house is better adapted for Cucumber growing in quantity, and at the same time quickly and well, than narrow span-roofed houses. These, if required specially for this work, need not exceed 10 feet in width, "out to out," as the builder would say, which gives an inside capacity of about 9 feet. Indeed, this is not infrequently the given width, clear of work, and in these days of dear bricks and dearer labour much is done with good 6-inch concrete walls, the latter the more simple when erected for Cucumber growing only, because, no side ventilation being needed, the walls of concrete can quickly be run up without the trouble of gauging the spaces where ventilation is required. Where rough gravel is abundant, as it is in some districts, there is a saving also of material by this being dug on the place. In my own case the best Cucumbers are grown in houses each nearly 100 feet long by 10 feet wide and 8 feet in the ridge over all, and with the ends on to south and north, or but very little removed from this. In these the early morning sun is secured, and the setting sun to quite a late hour in the evening. Other houses broadside to the south, while very hot during the hottest part of the

day, are not only slower in sending up the temperature in the morning, but require closing much earlier in the afternoon as a precaution against a too great fluctuation of night temperature, which in these heat-and-moisture-loving subjects is most important. Houses running north and south are much the best, because the benefit derived from solar heat during summer reduces the night changes to a minimum, so to speak, to the great benefit of the crop. Such houses of course require attention in shading, &c., which items will be referred to later on. Ventilation, also an important item, will of necessity be from ventilators hung to the ridge or by way of a complete lantern on the whole length of the ridge, which may be raised any height from an inch to a foot or thereabouts. Such means of ventilation in sharp-pitched houses such as these will be better than the ordinary lights to be raised by hand on the roof, for the reason that the latter would interfere with the training space on the roof as also be in the way of the workmen. I have mentioned but one style of house for the growing of this crop, for the reason that I am for the moment regarding Cucumbers as the crop, year in and year out. In many nurseries, where large houses are in the summer devoted to the work, the structures are 18 feet to 30 feet in width. But such places are not necessarily the best by any means, and neither training, watering, nor top-dressing can be done with the same ease or rapidity. More than this, these large spacious houses, by reason of the greater internal air space, so quickly dry up, unless most carefully watched. Splendid crops are, however, grown in them, and in certain seasons in particular, indeed, some of the most bountiful crops of fruit I have ever grown were in houses nearly 24 feet wide. All the same, I greatly prefer the narrow house, because the soil for top-dressing may be barrowed right in through the central path, from which also all training and other work can be done with comparative ease. There is, of course, no item of greater import than that of

HEATING.—This, it should be stated, must be adequate for the work. In all heating by hot water there is only one right principle, viz., a maximum amount of piping at a comparatively low temperature. Where it is the reverse it is not likely the best results will accrue. When the pipes are constantly heated to excess, insects and red spider put in an appearance. Nor is this the only drawback to insufficiently heated structures. In short, few crops more quickly resent checks and chills, and a crop considerably under the average in bulk as much as quality is one of the surest evidences of something wrong during the early stages. A night temperature of 60° during winter is needed to keep the fruits swelling uniformly; better still if a minimum of 65° can be maintained. For winter work, however, bottom-heat is an essential in some form or other, either conveyed by pipes or by the plants being grown on a side stage which is open to the warmed atmosphere of the house. Dry bottom-heat, however, has its drawbacks, that is, the bottom-heat produced from pipes encased by brickwork, with only apertures here and there for filling up the evaporating troughs. One of the best systems for a uniform bottom-heat is where the pipes lie in water, that is, a shallow cement trench just deep enough for the pipe and covered by slate slabs, boards, or corrugated iron. With such an arrangement the moisture-laden warmth is uniform, perhaps the most important item of all in this phase of Cucumber growing. Generally speaking, however, it is not adopted by market men, and the

next best thing is a manure bed within the house, or employing the raised side stages where the houses are best heated. The manure bed has several advantages, because it is not in the way for a succession crop. In this way with six or eight rows of 4-inch piping in a house 12 feet to 14 feet wide excellent crops may with good management be secured. In the summer-time artificial bottom-heat is best dispensed with altogether; it is, indeed, a detriment to a good crop of fruit, just as much as in winter it is both helpful and essential. During summer the whole of my Cucumbers are grown on a cold bottom, save in two places, where at different points frames with bottom-heat occur, and desirous of utilising all available space are planted in the usual way. In each case while accorded the same culture, save the watering, which is of necessity increased by the position, poor crops are the result. This is so year by year, independently of the fact that for several years various attempts were made to overcome it without success. Under these circumstances I cannot do other than point to the necessity of special precautions being taken, whether in market or private gardens, where the plants are put out on other than solid beds if a full and continuous supply of fruits is desired. Under no circumstances err on the side of insufficient piping, so that in early spring a temperature of 75° can readily be maintained. This is readily secured in houses 10 feet or 12 feet wide, with 2 feet of brick walls to the wall plate, and a ridge 7 feet high, that have not less than six rows of 4-inch piping. The pitch of the roof need not be excessive if a sunk path be made, utilising the soil therefrom to raise the side beds above the level of the soil outside, a not unimportant item in many localities. With the temperature named, it will be possible to cut the first fruits in six or seven weeks from the sowing.

PREPARATION OF THE SOIL is a matter too often forgotten, though it has an importance all its own. Of course there are soils that need but little preparation; many others, however, require a good deal, and it is singular that both classes are usually regarded alike by the cultivators. The top spit of an old pasture, so usually recommended for growing this crop, does not every day fall to the lot of the market grower who has to turn out Cucumbers in quantity, and more frequently old garden soil has to be brought into use. What was intended by "preparing" the soil has really to do with the growth of the plant itself, or rather in relation thereto. For instance, many, seeing they have a fairly good sod of soil, will rest content, and merely cut and stack it in readiness. Yet it does not follow that such a soil, albeit good-looking, should contain the requisite food for the crop in question. Too frequently it does not. The growth of the Cucumber in well-heated structures is altogether too rapid to be benefited adequately by the addition of manures of any kind to the soil in a half-crude state at planting time. Far better that this be done at least six months in advance, and be really incorporated with the soil in the readiest possible means for assimilation by the plant. Even good or old pasture soils may be greatly benefited in the same way, for these are very diverse in quality and equally deceptive, not only in its constitution, but also in richness. An old pasture that has been well done for possibly a generation is one thing, and as such quite a different article may be taken therefrom than much of the so-called "maiden loam," gathered too often on any bit of wayside common, where it cannot support the few blades of grass that gather together thereon.

The former may be expected to yield good results, while the latter can scarcely be expected to do so. Of such as these I warn all growers of the crop who have to make a living thereby not to be too much engrossed by the "maiden" side of the sod any more than the fibre it contains or the colour, all very good in their way, but by no means all-sufficient for producing the maximum amount of a crop of Cucumbers for, say, three months in succession.

RAISING THE PLANTS.—The chief item is that the seed be sound. Sow in boxes or pots of warmed soil, sufficiently moist to need no water at the moment, using a well prepared, rather sandy, and fairly light mixture. Sow thinly, cover lightly, and place or plunge on a brisk bottom-heat, say of 85° or so. Where a brisk heat is kept up for Eucharis, Gardenias, or such things, the young Cucumber plant will find congenial surroundings, and on the bottom-heat just named will be up in a couple or three days—a little longer, perhaps, when the sowings are made quite early in the year. With the first sign of a rough leaf the seedlings may be potted without the least delay, employing rich though light material, perfectly clean pots, into which merely drop the plants, with a slight knock or two to settle the soil. Avoid burying the plant deeper than is needed to stay it in position, and return the plants to the same heat as the seedlings, but without plunging. In cases where the seedlings have been raised in too great a heat there may be some tendency to softness of the stem, and the young plant is liable to damp when in too close a place. To obviate this, the pots or boxes of seedlings may be removed from the bottom-heat to a rather more airy position, with more room between. This will promote a certain firmness of stem that is fairly impervious to damping, at least with ordinary care in watering. From the first each plant must be staked. A few days on the bottom-heat will suffice to re-start the plants, when they will be best removed to the open side stages.

A GROWER FOR MARKET.

ORCHARD AND FRUIT GARDEN.

APPLE EMPEROR ALEXANDER.

This is an old and fairly popular Apple of Russian origin. When well grown it is one of the most handsome, the fruits large, bluntly conical in shape, inclined to fulness at the base, and with a closed eye; the ground colour yellow, but in many cases almost the whole fruit is suffused with deep red, and in others the red colouring resolves itself into broad streaks. The flesh is tender, too tender, in fact, to make it a popular variety for market, and during its season, which is a rather short one, lasting mostly only through October and November, it is of good quality as a cooking Apple, but light according to its size. Its handsome appearance has led to its being included among dessert varieties for exhibition, and it is often wrongly passed as a dessert variety, but it has no claims to the position from the standard of quality, and ought always to be disqualified when exhibited in the dessert classes. I find the tree a hardy, stout, but not over rapid grower: both the leaves and flowers are large, the latter very highly coloured and attractive when open or in the bud state. It makes a good orchard tree when grown in bush form. The habit is inclined to upright, but the heavy crops which the trees bear after they become established soon counteract the upright tendency and bring the outer branches into a horizontal position. The tree now and

then, but not often, misses a crop, but in fruitful years the crops of fine fruits brought to perfection are enormous, and if a good sale can be found for Apples early in the season, Emperor Alexander is bound to command the highest prices going at the time if brought to the consumer without blemish.

J. C. TALLACK.

Strawberry Latest of All.—I have nowhere seen this excellent Strawberry in finer form or cropping so well as at Clandon Park, Surrey. A recent writer referred to the variety as bearing closer planting than others because it was rather thin of foliage. At Clandon Park, where the soil is very stiff, the plants, after having been layered into pots, are put out in trebles in the rows, giving them ample room, and the ground is thus sooner furnished. Holes are taken out in the firm ground at proper intervals with a spade, some fresh soil put in, then the young plants

nets are put on some long straw manure is laid about beneath the bushes to prevent dirt splashing the fruit. No doubt we do not, as a rule, sufficiently hard prune Red Currant bushes. The way in which properly pruned wall bushes fruit shows how they like hard spurring.—A. D.

FRUIT GROWING ON LIGHT SOIL.

I WAS pleased to read the interesting account of "Currant Culture in Kent" (p. 93) by "G. H. H.," for it seems to renew old acquaintance with the Kentish fruit farms, of which I shall always retain a pleasant remembrance. When some years back I removed from Kent to the south coast, I soon found that, although I had brought the love of fruit-growing with me, I had not brought the depth of stiff, holding soil that fruit trees and bushes delight in, so that although I can grow the trees I cannot get the weight of crop from the light shingly soil. As "G. H. H." says, even in the most favoured county, one spot

Apple Emperor Alexander.

follow, and the fresh soil with some of the natural soil well pressed—indeed, hard rammed—in round them. That sort of treatment seems to suit Latest of All admirably. The breadths, as of all others grown, stand for three years. Royal Sovereign put out singly seems to need even more room than does Latest of All in trebles, as described.—A. D.

Red Cherry Currant.—I saw this superb Red Currant in fine fruit at Clandon Park recently. It is no doubt identical with that known as the French La Versaillaise, and certainly is the same as the wrongly certificated Jersey variety Comet. The practice at Clandon is to hard cut over the summer shoots as the fruit begins to ripen. The plants are thus kept dwarf; indeed, the bushes, when a net is thrown over them in the row, are not more than 18 inches in height. The result is, that whilst kept thus compact all danger from splitting is avoided and the bushes are remarkably fruitful. Before the

suits the Black Currant and another the Red and White Currants, and so on through all the varieties of fruits that are grown. Anyone starting a fruit farm should first of all be sure that the soil is deep enough, and of a texture suitable for the crops he hopes to grow, for it is costly work to try and alter the character of even a limited area of land. One of the greatest drawbacks to the culture of fruit on light soils is drought, and in this locality young trees grow freely and soon become fruitful, but in nine seasons out of ten the trees get checked by lack of moisture, with the result that the fruit drops or shrivels on the tree, and if the trees suffer for any length of time the next year's crop suffers as well. Stone fruits, especially Plums and Damsons, if once they get infested by red spider so that the foliage drops, take years to recover; in fact, I am now grubbing up some quite young trees, simply because they do not pay for the space they occupy. On the south coast this is the third year in succes-

sion when fruit crops taken collectively can be set down as a failure, for there are far more trees with scarcely any crop at all than there are with anything like a full crop. The question with the majority is not where they can find soil suitable for fruit trees, but how they can make the soil they have got more suitable for the many kinds they are expected to produce from it. Private gardeners cannot go all over the estate and select the spot most suitable for the fruit garden, but, as a rule, have got the position already set out. Market growers, or anyone that grows for profit, had far better discard any crop altogether for which the soil and position are unsuitable. After trying all sorts of fruits on suitable soil, and that which was quite the reverse, I have come to the conclusion that the safest of all fruits to give a fair return for labour and capital expended is Apples, for with the surface-rooting stocks and care in mulehing the roots, so as to conserve the moisture, one may get some return almost every year.

JAMES GROOM.

Gospolt.

NOTES AND QUESTIONS.—FRUIT.

App'e Devonshire Quarrenden.—This is an Apple that is widely grown. I think the greatest recommendation is its high colour. Regarding flavour, I consider there are several kinds ripening at the same time of higher flavour, Kerry Pippin amongst them. I have not so much to complain of regarding its flavour as its bad cropping powers. I have trees both in the orchard and in the garden, but none of them ever give a good crop.—DORSET.

New Strawberries.—Raisers of new Strawberries appear to me to have a great weakness for Waterloo as a parent. Why so I fail to see, as anyone who studies flavour will agree with me that Waterloo cannot be classed as first-rate. At least with me it is anything but first-rate. I am aware it is very late. Only recently I saw some new kinds highly praised because one of the parents was Waterloo. The cross had resulted in giving an earlier Strawberry than Royal Sovereign, one of the earliest we grow. I do not wish to depreciate the raising of new kinds, but there are other qualities besides value for travelling, mere size, and appearance to be considered. The quality should be the first point. In showing new fruits, plants also to show crop and habit should be shown, as gathered fruits are misleading, especially when examined in a bruised and uninviting state.—F. R.

ORCHIDS.

CYMBIDIUMS.

THERE is no species of Orchid more worthy of consideration than the Cymbidiums. The cultural requirements of the majority of the most popular varieties are within the reach of all in the possession of a greenhouse from which frost can be excluded. Let those inclined to doubt the cool system give it a trial and they will soon be convinced as to which is the better method. Some of the finest examples of good culture which it has been my lot to see are in the collection of Sir F. Wigan at Clare Lawn, East Sheen. These plants are grown in a cool rock fernery, from which Mr. Young tells me there is a difficulty in excluding frost, the temperature often falling below 40° on cold nights. These plants leave nothing to be desired as regards freedom of growth and vigour, while the flowers are produced in such a manner as to draw the admiration of all whose privilege it has been to see them, some of the plants carrying upwards of two dozen spikes, the flowers being also fine in substance and in colour. In Mr. Little's collection at Twickenham the cool system has been followed up for years with desirable results. In the collection of which I have charge I have followed this system for the last five years with

the greatest success. Previously to my taking charge of this collection the plants had been grown in the house with the Vandas, the result being that there was always a difficulty in keeping the plants clean. The growths were weakly and the flowering unsatisfactory. Through additions being made to the glass structures about a year after, opportunities were given which induced me to remove them to quarters where the conditions better agreed with my own ideas as to the requirements most suitable for the successful culture of this species. They have been grown under these conditions for the last five years, with results that warrant me in making the declaration as to the cool requirements at the commencement. The house is a lean-to structure, with an almost eastern aspect. Fire-heat has never been used during the five years the plants have been in the house, unless there has been an indication of frost. There is only a flow and return hot-water pipe in the house, which shows the amount of heat obtainable even in cold weather. The temperature often falls to 45°, and has been down even to 40°. Hanging on the roof is the Chimera section of Masdevallias, while on a shelf at the front is a quantity of the large-flowered Masdevallias of the M. Harryana and M. Veitchei section. The principal condition to be observed in the cool treatment of Cymbidiums is careful attention to watering, and the moisture in the atmosphere during the period of dull, cool weather. I usually keep the house at a temperature of 50° under ordinary circumstances; that is at about the same heat as that usually given to *Odontoglossums* in winter. In summer the conditions differ inasmuch that the house is kept rather closer, with a more humid condition of the atmosphere maintained to render the plants every inducement to properly mature their growth. I find that under these conditions red spider, which is usually so destructive and troublesome with this species, is considerably lessened; other insect pests also are kept in check. In bright weather during the hot summer days the plants are liberally syringed overhead in the morning, the afternoon syringing being omitted.

The potting compost consists of two parts fibrous loam, to which is added a liberal sprinkling of rough sand or broken crocks. As the plants require plenty of water during the growing season, it is advisable, therefore, to maintain the compost in an open and porous condition. The pots used should be thoroughly clean and drained to one-third their depth with clean crocks. The best time to repot the plants is immediately after the flower-spikes have been removed in the spring. The usefulness of the flowers of such varieties as *C. giganteum*, *C. Lowianum*, *C. Traceyanum*, *C. cyperifolium*, and others in this section is demonstrated principally in their durability, either by remaining on the plants or used for cutting. I have had examples this season of *C. Lowianum* lasting in perfection six weeks after being removed from the plants. I have known instances where flowers have been in good condition for three months where they have been kept cool and allowed to remain on the plants. It is therefore necessary, owing to the lasting qualities of this section, to observe carefully the condition of the bulbs, for there is considerable danger in overflowering the plants. It is always advisable, for the benefit of the plants, that the spikes should be removed after they have been expanded a reasonable period. This is especially desirable the first season after the plants have been repotted.

A brief note on the species and hybrids, with a short description, will perhaps not be out of place here.

CYMBIDIUM CANALICULATUM is a native of Australia. It produces long racemes densely covered with small but interesting flowers, the sepals and petals brown margined with green; the small three-lobed lip creamy white, with purple markings. There are considerable variations of this species. One variety recently exhibited at the Royal Horticultural Society's meeting was wholly of a rich plum-purple colour. It is an easily-grown species.

C. DEVONIANUM first flowered in this country at Chatsworth in 1843, having been sent by Gibson from the Khasia Hills in 1837. It is a dwarf but robust growing species, producing broad leaves 12 inches to 15 inches long. The racemes are about 12 inches in length, thickly covered with small attractive flowers. The sepals are pale green suffused and streaked with brown; the lip deep reddish-purple, mottled with greenish white. It requires a position where plenty of light can be procured in the cool intermediate house. It is a free-rooting species, and should have a liberal amount of pot room.

C. EBTENEUM.—This handsome and well-known species with its ivory-white flowers, with purple spottings on the lip, is one of the most useful *Orcidids* in cultivation. It does well under the cool conditions referred to above.

C. FINLAYSONIANUM is better known in gardens as *C. pendulum*. It produces long racemes of purple and white flowers. It is best grown in the warm intermediate house. There is a variety of this named *C. F. atropurpureum*.

C. GIGANTEUM is an early-flowering and most useful variety. The flowers are each about 4 inches across; sepals and petals light greenish-yellow, veined with rich red-purple, the front lobe yellow spotted with red, the side lobes lined with the colouring of the sepals and petals. It thrives well with the cool section.

C. GRANDIFLORUM (*Hookerianum*).—This is one of the most distinct and beautiful varieties in cultivation, but unfortunately it is usually a shy flowering variety, and is very seldom seen in bloom. It is worthy of every consideration, and should be included in every collection. The flowers are each about 5 inches across, the petals and sepals pale green, the lip light yellow with lines of purple dots on the inner side, the intermediate lobe fringed at the margin, yellow, spotted with red-purple. It grows satisfactorily in the cool division as advised above.

C. LOWIANUM is the most satisfactory and useful of the whole section to grow for cutting. Its greenish yellow sepals and petals and white and purple lip are too familiar to need further description here. Its constitution leaves nothing to be desired, and it thrives well under the cool conditions as advised.

C. TIGRINUM.—This should be in every collection. It is a miniature-growing species, and is best suited for basket or pan culture. A fine example of this was included in Sir Trevor Lawrence's group at the last Temple show. The sepals and petals are each 2 inches long, light green, spotted and suffused with red at the base; the front lobe of the lip white, streaked with purple-brown; the side lobes yellow, striped with broad reddish brown bands. The flowers are usually produced three or four on the spike. It requires a long resting season and does well under cool conditions.

C. TRACEYANUM.—This is by far the largest and most beautiful of Cymbidiums. It first flowered in the nursery of Mr. H. A. Tracey at Twickenham, having been procured by him in Stevens' auction rooms among an importation of *C. Lowianum*. It was afterwards sold, and passed into Baron Schroeder's collection, where it was highly prized and looked upon as a unique plant by all Orchid enthusiasts until during the last three years plants have cropped up from importations, and it has now become a familiar feature in almost all collections of note. The flowers are each upwards of 6 inches in diameter

pale greenish yellow, spotted with reddish brown; the front lobe of the lip creamy white, with reddish brown spots; the side lobes light yellow, streaked with the reddish brown of the front lobe. It is highly perfumed, and is a most attractive, useful, and desirable variety. It has a good constitution, growing and flowering freely under the cool conditions referred to above.

C. CYPERIFOLIUM has flowers very similar in markings and colour to those of *C. Traceyanum*, but the flowers are little more than half the size. The habit of growth is totally distinct. It is a pretty, desirable and useful form, thriving well under the conditions recommended above.

C. MASTERSI and *C. ELEGANS* also do satisfactorily under the cool system, both growing and flowering freely.

There are three distinct hybrids that have flowered up to the present. Two of these at least have the intermediate characteristics of the two parents. The third, *C. Winnianum*, indicates that *C. Mastersi* was one of its parents to such an extent as to suggest a mistake having been made in its recorded parentage.

C. EBURNEO-LOWIANUM was raised in Messrs. J. Veitch and Sons' nurseries from the species indicated in the name. It has the characters of the parents both in habit of growth and in its flowers. The sepals and petals are creamy yellow, of fine form and substance; the front lobe of the lip has a V-shaped crimson-purple blotch; the remainder creamy yellow, with a bright yellow disc. It does well under cool conditions and is a most desirable form. It has been recorded during the past spring in THE GARDEN report of one of the Royal Horticultural Society's shows that a plant of this lovely hybrid had flowered in a small collection of Orchids at Worthing from an imported plant. It has also appeared in a north of England collection in a similar way. If natural hybrids are likely to crop up in importations of *C. Lowi* in this way they should soon become more plentiful and generally grown, as they deserve every consideration.

C. LOWI EBURNEUM is a Continental-raised hybrid, the principal difference being in the pure white segments instead of the creamy yellow ground as seen in Messrs. Veitch's hybrid. As the name implies, it is the reverse cross of the previously mentioned variety.

C. WINNIANUM.—The parentage recorded is *C. giganteum* × *C. eburneum*. It was raised in the collection of Mr. C. Winn at Birmingham. The flowers are each about 4 inches across, the sepals and petals ivory-white, the small lip ivory-white, densely spotted with crimson on the side lobes. It is a most distinct and pretty hybrid, possessing a good constitution, and is worthy of consideration. H. J. C.

Odontoglossum bictonense album.—In place of the usual rosy tint on the lip, this pretty variety has that organ pure white, and this gives a spike of flowers a much lighter appearance. The other segments are deeper in colour than usual, being a deep reddish brown in place of the usual greenish tint. This latter is, however, occasionally seen in the type form. Although an old species, *O. bictonense* is still worth growing, the tall spikes of flower appearing now and lasting a long time in good condition because of the number produced. It does better with rather more warmth than the majority of species.

Oncidium prætextum.—Many of the crispum set of *Oncidium*s are fine garden Orchids, and this, with its tall arching panicles of fragrant flowers, is no exception. These individually are about 1½ inches across, brownish, with flaky blotches of golden yellow in the type. In other varieties the yellow is more prominent and the brown less so. It is not easy always to get this plant to grow freely, the strain of flowering being very great. Many plants of it are killed by stuffy hothouses and a too liberal mass of compost. They like best a thin layer in shallow

baskets or on rafts and a place not far from the roof-glass in the Cattleya house. Here the pseudo-bulbs grow hard and strong, and if the flowers are removed after being a reasonable time open the plants should keep healthy. It is a native of Brazil and was introduced in 1873.

PUBLIC GARDENS.

HOLLIES IN GROSVENOR PARK, CHESTER.

THE old cathedral city of Chester possesses one of the prettiest little parks in the United Kingdom, and its specimen Hollies stand, I believe, unrivalled for number, size, and health. This Grosvenor Park is about 16 acres in extent, and was presented to the city by Richard, second Marquis of Westminster, and opened on November 5, 1867. Its undulating surface and sloping banks, skirted by the river Dee, were utilised to the best advantage. The Hollies all over the park are in robust health, and vary from recently introduced ones to specimens 30 feet in height. Hollies and Limes alternately line the sides of the principal walks. Unfortunately, the mistake of neglecting to reckon with the future is too apparent here, for instead of planting both Hollies and Limes 20 feet at the least back from the edge of the walks, they have only been allowed a space of 6 feet. In all likelihood immediate effect was desired, but when this had been obtained and the error seen, the plants should have been shifted another 12 feet or more from the walk. To attempt the removal of these grand, healthy specimens now would be both costly and risky, and perhaps a better remedy would be to plant a second line where the first ought to have been. Twenty years hence would see them fair-sized plants, and the present lot might then be dispensed with. At present all these Hollies along the walk-sides have to be severely cut to confine them to their allotted space, which is a diameter of 12 feet at the base. This confined base leads to the formation of an acute angle between the two extremities in preserving the conical appearance they now possess. In spite, too, of the severe pruning they get annually, many of the plants are encroaching upon the walks, which, by-the-by, are certainly not too wide for principal promenades.

The exceptional fertility of the soil is not limited to the growth of Hollies only, for nearly every shrub within the park is a picture of vigorous health. There are some bushes of *Spiræa arifolia* 15 feet through and as much high. These were literally covered with their creamy white flowers at the middle of July, and stood out conspicuously against the dark green foliage by which they were surrounded. This *Spiræa* is certainly not so extensively grown in private places for the embellishing of the lawn, shrubbery, and the drawing room as its merits entitle it. The white Broom is represented by unusually large bushes at odd corners in some of the shady parts of the park. *Laurustinus*, *Escalonia*s, *Garryas*, *Robinias*, *Cratægus*, *Cydonias*, the Service Tree, and many other kinds of flowering trees and shrubs are associated with evergreens, and are luxuriating in the rich soil of which they bear evidence. The proximity of the Grosvenor Park to the river Dee may in a measure account for the healthy appearance of the trees and shrubs. Herbaceous plants, too, grow with unusual vigour compared with those met with in similar situations, and their extended cultivation, or at least those of more stately growth, in masses along the margins of shrubberies might with advantage be encouraged. For this purpose there is any amount of material to select from. Nice good-sized masses at irregular distances along the margins of the shrubberies would materially add to the beauty and interest of the park.

Small as the Grosvenor Park is, it is not without its lake. In this are a few plants of the white Water Lily, which look very pretty. The

last thing, but certainly not the least important, that I should like to draw attention to in connection with this park is an attempt at a botanic garden. A botanic garden in connection with a centre of learning is a decided advantage to students (for a practical lesson carries more conviction and is more lasting in its effect than a purely theoretical one); therefore when one is lacking, as at Chester, a public park is just the place to make up the deficiency. Seeing that the city of Chester is, apparently, still insensible of the value of a botanic garden as an auxiliary to education, all praise is due to the Natural Science Society for the efforts it has made in the Grosvenor Park to supply this want. There is, nevertheless, a good deal more needed to make this botanic arrangement complete. Some of the orders have got into the wrong class. A few orders are without representatives, while a few stand much in need of additions in variety. It might have been better, too, if British plants only had been selected in this botanical arrangement. The only representative of Solanaceæ is a Tomato plant, and the Polygonaceæ group contains a fine clump of *Polygonum sachalinense*. For educational purposes—the study of botany—only British specimens are used, and it should, therefore, be the aim of the Natural Science Society to group under the respective orders the best British representatives of each. J. RIDDELL.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

The floral committee met in the society's gardens at Chiswick on Tuesday last, 16th inst., and gave awards of merit to the following sent for trial this season:—

TUFTED PANSY BRONZE QUEEN.—A flower of moderate size and fair form; colour rich deep bronze, upper petals bluish purple. It is free-flowering and the habit is fairly dwarf. This is a flower which, to be appreciated, will largely depend upon individual taste.

DIANTHUS CHINENSIS FLORE PLENO (double Indian Pink).—Large handsome double flowers of this barely annual, colours rich and varied.

DIANTHUS CHINENSIS LACINIATA FLORE PLENO.—An interesting and pleasing form, with large double-fringed blossoms of various shades of colour.

CANNA WILLIAM MARSHALL.—A seedling raised at Chiswick, with large individual blossoms of good form, though rather flimsy. The flowers are neatly margined rich golden yellow, the centre of the petals being bright orange-scarlet, spotted with a deeper shade of the same colour. The orange lip, which is of large size, makes up a flower of unique colouring.

CANNA STRADRATH HEIDENREICH.—A very handsome and large spike, carrying magnificent individual blossoms of good form and substance; colour rich glowing crimson. Its richly tanned foliage contrasts beautifully with the highly-coloured flower.

CANNA COMTESSE DE VARTOUX FLORENCE.—This is a charming plant, being beautifully dwarf and freely flowered. The colour is best described as rich orange-yellow, freely and neatly spotted rich crimson. The flowers are of good form and very effective.

CANNA PARTENOPE.—A splendid orange-apricot flower of large size and of good form and substance.

The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, August 23, in the Drill Hall, James Street, Westminster, 1 p.m. to 5 p.m. At three o'clock a lecture on "Perpetual Fruiting Strawberries" will be given by Mons. Henry de Vilnoria.

A Swiss National Chrysanthemum Society.—National Chrysanthemum societies seem to be the vogue just now, and the popular Eastern

flower seems to find enthusiastic adherents in countries where a society has not yet been started. We notice in *Le Chrysanthème* that a Swiss National Chrysanthemum Society has just been started in Geneva, that the rules have been drawn up and circulated and all preparations made for a show in November. M. David Brunet is president, and M. Louis Verréard secretary.—C. H. P.

Italian National Chrysanthemum Society.—This newly-constituted society has just issued the first number of its Journal, which compares very favourably with that issued by the French society, being better printed and on much stouter paper. It contains amongst other things a list of officers and committee men, among whom we notice Messrs. Scalarandis (gardener to the King of Italy), Radacli, Briseoc-Ironside, Longhi, &c., all well-known Chrysanthemum men. Then follow the rules of the society and a list of the persons at present forming the society to the number of about 160, among whom we notice the names of a goodly number of French and English notabilities in the Chrysanthemum world.—C. H. P.

NOTES OF THE WEEK.

A white Thistle.—In answer to "V. B." in last week's GARDEN, I should like to mention that in walking from C'errhilly to Cardiff on Saturday last, Mr. A. Pettigrew, Jun., and I came across several white-flowered plants of *Cnicus lanceolatus* growing alongside the road.—W. J. THUTCHER.

Canna Comte de Bouchard.—This is a very handsome variety, the flowers of large size, splendid form, and carried on spikes of the most elegant description. The colour is a beautiful bright golden yellow, with neat spots of bright red. The green foliage contrasts pleasingly with the flowers.

Abutilon Swatzi is the name of a neat and prettily variegated Abutilon that should prove helpful in many arrangements in the garden, conservatory, or sitting-room. The foliage is somewhat small and the habit inclined to pyramidal, while the variegated portions are as light and freely marked as in the well-known variegated *Acer*.

Cyananthus lobatus has been among the prettiest of rock plants for some time, the growths studded with flowers that are quite out of the ordinary style. Indeed, a few such things as this appear more than usually content with the dry and warm conditions of the present summer, and this lovely Himalayan plant is one of their number.

Chrysanthemum Early Blush.—This old variety is one of the earliest to flower, and may be had in fine condition towards the end of July and during the present month. The blossoms at this season are very chaste and beautiful. The colour is a rosy blush, the flowers of neat and even form, and produced freely and continuously for six weeks or more.

Gaultheria trichophylla.—One more note on this plant. Most of the berries have ripened and shed their seed, and there is again—I cannot say a fine display of flowers, because they are carefully hidden by the foliage—now a large number of flowers. Have any of your correspondents seen this *Gaultheria* flower a second time?—E. C. BUXTON, *Coed Drew, Bettws-y-Coed*.

Phlox Lord Rayleigh.—Usually the tints of blue and violet in the herbaceous Phloxes are of an objectionable shade and washy besides. In the above kind we have a very distinct shade of colour—a violet-blue tone—that should prove as effective as it is novel and distinct. The usually washy slaty blue tint has no existence in this variety, the most pronounced and novel of its class we have seen.

Hollyhocks.—The heat and drought of this summer have apparently just suited these plants, disease being almost unknown in many collections. It is impossible to describe the charm and beauty of many of the single forms so easily and readily raised from seed. In a garden where shrubs fill every available inch a few plants even of an ordinary strain of Hollyhocks constitute a welcome change.

Chrysanthemum Bronze Bride.—This useful pompon, a bright reddish bronze sport from the well-known rose-lilac Blushing Bride, is just now at its best in every warm and sheltered garden. In more

exposed situations its flowers will be welcome a fortnight later. It is wonderfully free-flowering and rarely exceeds 2 feet in height. It sported in 1894 with the late Mr. W. Piercy, who almost lost the stock in the succeeding winter.

Heliopsis patula. Compared with perennial Sunflowers and other allied plants, the flower of this is small; still, for all this, it is by no means to be ignored. The rich orange-gold of the ray florets, so very firm in their substance, and the good stiff stems on which the flower-heads are borne, make it an effective subject in the border as well as in a cut state. The habit, too, is by no means gross or so rampant as is the case with many things even when good culture is given.

Carnation Countees of Salisbury.—I send one or two more blooms of Countees of Salisbury. I have grown this variety for years. It does not split and is a splendid late-flowering yellow, better than many of the new ones, very hardy and reliable in the open border.—H. W. WEGGELIN.

** We hope this variety will not be sent out until it has had a good trial in different soils and situations. We fear these yellow varieties are of little value for the open air.—E.P.

Astilbe Gerbe d'Argent.—This, which comes to us from Mr. Cuthbertson, Rothsay, has large erect branching spikes of white flowers tinged with pink. The spikes stand about 2 feet high, 15 inches of this being covered with bloom. It is a welcome addition to the hardy flower border and is deserving of general cultivation. It was well shown at a recent meeting of the Royal Horticultural Society.

Spiræa Bumalda at Arbigland.—At Arbigland, Dumfries, hardy flowers are more largely grown than in former years. In looking over the borders last week I was pleased to see *Spiræa Bumalda* and the variety *Anthony Waterer* in fine condition. The dry weather has affected them less than one would have anticipated, and they made a fine show with their bright flowers. In my own garden they suffered from drought more than usual, but are flowering well still.—S. ARNOTT, *Carsathorn, by Dumfries, N.B.*

Campanula Elatines.—Good plants of this pretty species are by no means common in hardy plant collections, a fact which is in a measure due to the frail nature of the stems and growths that appear to emanate mostly from a central stem, as in *C. fragilis*, and are very liable to snap off. The flower individually is small, yet one of the most intense of the blue shades, indeed almost violet-blue as it expands. For the reason stated it is best if given a sheltered place in the rock garden in a position as free as possible from rough winds.

Tulipa persica.—Now that the time for ordering bulbs is approaching, a few words in favour of the dwarf Persian Tulip may be appropriate. For rock gardens it is of special merit, and I was pleased to see a good clump in bloom last June in the picturesquely arranged rock garden of Lord Ardilann at St. Anne's, Clontarf, Dublin. *T. persica* is very attractive when its bright yellow flowers open out in the sun. Its dwarf habit enables one to grow it where taller flowers would be out of place, and it has been a favourite with me for a good many years.—S. ARNOTT.

Tulip Fairy Queen.—Bulb catalogues remind us of some desirable flowers. Among these a catalogue just received recalls *Tulip Fairy Queen*, which was in bloom at Straffin, co. Kildare, about the middle of June. I afterwards saw it at Glasnevin. Although not so brilliant in colour as many of the Tulips it is remarkably beautiful. The flowers are large, and may be described as yellow and heliotrope coloured when newly open, but passing off a pretty fawn. It grows about 18 inches high. A comparatively inexpensive Tulip, it ought to be more largely grown.—S. ARNOTT.

Phlox Diadem.—Late-flowering Phloxes in this district have suffered greatly from the long-continued drought, which has only passed away within the last fortnight. Even in soil in the best condition the loss of the lower leaves, the dwarfness of the plants, and the smaller spikes

show the effects of the dry weather. In the garden of Colonel Blackett, of Arbigland, Dumfries, I observed some good Phloxes in the herbaceous borders the other day. Among these the best was the white *Diadem*. It is not so pure as *Panama* or *Sylphide*, but has a better spike than the former.—S. ARNOTT, *Dumfries*.

Linaria repens alba.—But for its rambling propensities this graceful Toadflax would become more favoured in the border of hardy flowers or the rock garden. It runs so rapidly at the root, however, that it would be well to avoid planting it in the latter or beside the more valuable plants in the border. A corner to itself would suit this pretty white *Linaria* better than anywhere else, and one could imagine how pleasing a mass of it would be in some nook where it could ramble at will. I saw a good plant at Kirkcubright, New-abbey, N.B., the other day. It was more compact than most plants I have seen before.—S. ARNOTT.

Platycodon grandiflorum album is one of the most beautiful of really choice perennials. The plant is not less vigorous than the type, and though not pure white, is somewhat purer than the kind known as *pallidum*, which is rather heavily flushed with blue. At the same time it is a very useful and also an attractive plant, and, seen in company with the deeper blue shades that predominate in this class, all the more acceptable. These *Platycodons* appear to delight in a soil not only of considerable depth and richness, but with grit added quite freely. Beyond this, a partially shaded place, if not indeed essential, is most helpful in prolonging the flowering.

Eucryphia pinnatifida.—This is certainly one of the handsomest shrubs in flower at the present time, and worth a choice position in the garden. Planted on the grass at Kew the plant made but little growth, and then the flowers were not only small, but not nearly so abundant as they should be. Given more shelter, this beautiful bush-like shrub should make much more vigorous and clean wood, and in turn produce also blossoms in plenty. The flowers are pure white, rather cupped, and rendered conspicuous by a large tuft of anthers that are effective when the plants are freely flowered. Flowering examples of this beautiful bush were shown at the Drill Hall last week by Messrs. Veitch.

Lilium Batemanæ.—This has always been a popular Lily by reason of its colour, a reddish apricot, that combined with the erect cup-like flowers makes it most effective in groups in the garden. This Lily does fairly well in the open garden, one of the chief essentials to such a condition, however, being a good depth of thoroughly open material as opposed to those soils that lie close and sooner or later become sour about the bulbs, and where this is the case failure quickly ensues. Good soil with ample drainage should be among the first things to receive attention by those embarking in the cultivation of the choicer Liliams. The above kind is only some 2 feet high, and always pleasing and attractive.

Hydrangeas in S.E. Kirkcudbrightshire.—The Hydrangeas are, as a rule, excellent shrubs for gardens near the sea, and some attain to a large size in the S.E. of Kirkcudbrightshire. In some cottage gardens good specimens are seen, but the finest in the district are, I think, in the garden of Colonel Blackett, of Arbigland, where there are two huge bushes of *H. Hortensia*. I have known them for a number of years, and this season, while the panicles of bloom are smaller on account of the drought, they are more numerous than before. Mr. W. Houlston, the gardener at Arbigland, finds they do better if left unprotected in winter than if covered, as was the practice at one time in the garden. They are well sheltered otherwise.—S. ARNOTT.

Campanula garganica hirsuta.—There are many members of this genus with larger flowers than this, but very few indeed that are more profuse in their flowering, and, being also of easy culture, there is no difficulty in quickly forming

good patches of it. The variety in question is perhaps best suited to the rock garden, or at least a position where the plant may freely develop and trail over stones or earth. Frequently excellent results follow the placing of this plant in the crevices of old walls, for which purpose it is well suited, and when in flower the free and profuse masses of its rather starry blossoms render it among the most effective. Equally satisfactory is the typical species, though in the flowers alone there is not a great difference, both kinds having soft or pale blue flowers shading to white.

Gentiana septemfida.—A very fine group of this lovely trailing Gentian has been flowering splendidly for some time past in the rock garden at Kew. The group in question is perfectly happy, both growing freely and flowering abundantly, in a position where a good-sized piece of rock affords shade of a permanent and uniform character not only to the growth, but also to the plant when in flower. Above and beyond this, though the condition may too frequently be overlooked in the cultivation of many a choice plant, is the uniformly cool condition existing about the roots. Though the above plant is not usually cited as difficult to manage, it is at the same time not usual to meet with it in such vigour and flowering so well. The shade of blue and the abundance of its flowers are just now a great attraction.

Chrysanthemum Mme. Marie Masse.—Some capital flowers of this kind secured the award of merit at the Drill Hall on the occasion of the last meeting, a fact which at once proves it to be among the earliest of early-flowering sorts. It is, however, possible, judging by the excellent condition of the blooms, that the plants from which they were taken were grown in pots and the flowers protected when expanding. Assuming this to be the case, this does not exactly meet the requirements of the early border Chrysanthemum as intended by the latter term, though there is every proof of its earliness by some plants flowering early in July in the open. These, however, were somewhat premature, and the plants made little growth, while producing a fine head of bloom at about 12 inches high. The major portion of the same batch, however, will not be in bloom for some time to come.

The American Water Lily.—I have sent this morning a box containing a Water Lily which has sprung up in one of the ponds that I have made for Lilies here. I shall be much obliged if you will kindly name it for me in your next number of THE GARDEN. You will notice that the flower is an imperfect one, but it is the only specimen that has showed itself. My gardener has also enclosed two flowers of the common yellow Water Lily for comparison. The leaves of this plant are erect, like Arum leaves, and do not lie flat on the water like the ordinary Nuphar. In the pond with this plant, which first showed itself last year, are also Arums, *Aponogeton distachyon*, and *Nymphaea odorata*. All have flowered. Is it possible that this can be a hybrid?—E. H. T.

* * It is, we think, the American Water Lily (*Nuphar advena*), a seed or bit of which no doubt came in the soil with some other water plants. It is a very vigorous plant, and apt to come up where it is not wanted.—ED.

Linum arboreum seeding.—In THE GARDEN of August 6 (p. 111) it is said that *Linum arboreum* may be raised abundantly from seed. It has never been known to produce fertile seed in England, but is confused with *Linum flavum*, a very hardy and prolific species, which seeds abundantly in English gardens (at least in mine). These two species have been confused in high quarters. Twenty years ago both were growing in Kew Gardens under each other's name, and I called Sir J. Hooker's attention to it and got them set right. It was owing to this mistake that Charles Darwin in his "Different Forms of Flowers" chapter iii., states that *Linum flavum* has "never been known to make seed in cultiva-

tion." The confusion, however, has less excuse, for in that popular and excellent work *The Botanical Magazine* both were accurately figured and described in the last century by Curtis, *Linum arboreum* as a "greenhouse shrub," in vol. vii., tab. 234 (A.D. 1794), and *L. flavum* as a "hardy herbaceous perennial," vol. ix., tab. 312 (1795).—C. WOLLEY-DOD.

Sternbergia macrantha.—This handsome species, which is now flowering in the open from collected bulbs, is without doubt the largest and most vigorous of its race, and worthy of general cultivation either in the border or the rock garden. The large yellow blossoms are not unlike those of a Meadow Saffron in point of size and form, but possessing rather more substance, are therefore firm, and in the bud state quite attractive also. The bulb is more globular than in other kinds, and in the present instance quite leafless. Judging, too, by the vigorous root action immediately on contact with the soil, there would appear but little fear of the bulbs becoming well established, and if so, it would prove a welcome addition to this class. At the last meeting of the Royal Horticultural Society, Messrs. Wallace and Co., Colchester, set up a group of this handsome bulbous plant in flower, the large golden yellow cups securing a good deal of attention. The examples referred to were about 5 inches above the soil, but would no doubt exceed this when established.

Lychnis Haageana is one of the showiest of all the hardy plants now in bloom, the colour or varying shades of colour brilliant in the extreme, coupled with large blossoms that are borne quite freely where the plants are strong. This strain of *Lychnis* differs in its roots from all else, and on account of their small size in winter are apt to be overlooked unless the position is well marked. All the kinds in this section are strictly herbaceous, not a vestige of growth remaining above ground, while below, the fleshy roots, which are short, incline to be of a tuberous character. Fortunately, the plant produces seeds in plenty, and these may be sown thinly in the open ground as soon as gathered, there to remain till the first flowering of the plant, when the best colours may be selected and planted in groups. There is also considerable variation in the size of the flowers, and by discarding the inferior forms for a year or two a strain of some excellence should result. Rich and warm well drained soil suits them well; in close clay soil the tuberous roots often decay and disappear in winter.

The weather in West Herts.—A very hot week. On three days the highest temperature in the shade exceeded 80°, and on two of these days the readings were respectively 84° and 83°, both of which are the highest shade temperatures recorded here during the present summer. The nights were also very warm, and on that preceding the 16th the exposed thermometer did not fall lower than 58°, which is the highest minimum reading registered by this thermometer in any August for, at all events, the past thirteen years. During the week the temperature of the ground has risen very rapidly, the reading at 2 feet deep being now about 4°, and at 1 foot deep 6° warmer than is seasonable. Half an inch of rain fell during a thunderstorm which occurred on the early morning of the 16th, and for five minutes rain was falling at the mean rate of more than 1½ inches an hour. Some rain-water has come through both percolation gauges on each of the last two days. Previous to this no water at all had come through either gauge for a month, and no measurable quantity for over five weeks.—E. M., *Berkhamsted*.

Weeds.—Gardens ought to be clean and tidy, for what looks worse than crops of weeds? The injury done by a heavy crop of weeds and their removal in autumn is not remedied in one year, for, no matter how naturally fertile the soil may be, the exhausting effect of the weeds will render it

miserably poor. Heavy dressings of manure will in time bring it back to the maximum of productiveness. The period required to accomplish this desirable condition will, however, depend on the soil. Some compositions will "cook" the raw plant food more quickly than others, while the worst forms may take years to rectify. Weeds, therefore, ought always to be kept under. By keeping the Dutch hoe going among growing crops in dry weather the weeds are not only killed, but they act as a manure and the soil is improved by the stirring. Besides these advantages, evaporation in dry times is to a certain extent diminished and the garden made to assume a kept appearance, affording interest and pleasure to all connected with it. In gardens, too, where a vigilant eye has been kept on the weeds for years and they are not allowed to flower or seed, one person can get over a very much larger portion of ground in a day with a hoe than he could where weeds have been allowed unrestricted growth. There is also very little expense connected with the keeping of a garden in a tidy condition and free from weeds with the use of the hoe compared with the expenditure on the neglected gardens we sometimes come across, and the haphazard methods employed in their management. Every effort should therefore be made to keep weeds down in order that the crops grown upon the land may have the exclusive use of the plant food within it, and the garden yield the pleasure and profit for which it was intended.—J. RIDDELL.

LAW.

Action for the loss of MS. of book on forestry.—At Leeds Assizes, on August 11, Mr. Justice Day and a special jury heard the case of *Simpson v. Bain*. In this case the plaintiff, Mr. J. Simpson, forester to the Earl of Wharcliffe, Wortley Hall, Sheffield, brought an action to recover damages from Mr. A. Bain, bookseller and printer, Sheffield, for the loss of MS. intended for the publication of a book. The plaintiff took the MS. to the defendant to be type-written, and it had to be returned to him. The plaintiff handed the MS., which contained chaps. 9, 10 and 11 of the work, as also an original sketch of a forest near Newry, to the defendant, telling him that he had no other copy, and that it could not be replaced. The MS. and the type-written copy were to be returned by Christmas. On January 29 the plaintiff was informed that the MS. had been lost. The jury were instructed to assess the pecuniary value of the MS., which had cost time and money to prepare, and on consideration of the case awarded the plaintiff £100 damages with costs.

OBITUARY.

MR. JAMES PULHAM.

WE regret to announce the death at the age of 78 of Mr. James Pulham, which took place at Broxbourne on Thursday, August 10, after a week's illness. Mr. Pulham had long been one of the best-known men in the garden trade, and was the maker of by far the largest number of rock gardens in the country. He might be said to be the originator of works of this kind far in effect above the old clinker rockeries shown in Loudon's books and many others. Mr. Pulham retained his interest in the work until within a week of his death, and there is hardly a county in England in which examples of his work are not to be seen.

Names of plants.—*F. M.*—1, *Hieracium lactucaefolium*; 2, 3, *Leontodon hispidus* var. —*G. H.*—*Ixora Williamsi*. —*E. H.*—*Saxifraga Boydi*, a cross between *S. Bursleriana* and *S. aretioides*, raised by Mr. Boyd, Cherrytrees, Kelso, N.B., in 1890. See account with coloured plate in THE GARDEN of July 5, 1890 (p. 10).—*A. B.*—1, *Adiantum cucumatum*; 2, *A. scutum*; 3, *A. trapeziforme*.

THE MARKET GARDEN.

CHERRIES IN KENT.

CHERRIES are among the most popular and profitable of English fruits, and yet as a market crop their production is practically monopolised by growers in Kent. With very few exceptions one might travel through the whole of the home counties without finding a Cherry orchard, proving that there is either something wanting on the part of growers, or else that there are few places where the fruit succeeds well enough to merit its being planted on a large scale. This state of affairs has not escaped the notice of writers on the subject, who, without perhaps fully considering the question—and an important question it is—of soil and situation, have urged the planting of Cherries on a large scale in other parts of the country. So far as I know, Cherry growing makes no great advances anywhere except in Kent, and there in districts suitable for the crop fresh orchards are continually being planted, and hillsides and valleys that once grew hops and corn are now flourishing young Cherry orchards.

In private gardens Cherries generally are grown in the orchard house, or else occupy a favoured position on a wall where the blooms can be protected and the fruit watched and tended until it is ripe. In the Cherry-growing districts of Kent, however, the Cherry needs no nursing, and the hundreds of acres of trees set out in regular lines in the orchards are not only evidence that soil and situation are suitable for the production of this delicious fruit, but also that the growers are well versed in its cultivation. Experience has taught them that the Cherry is fastidious, and without regular and proper care and attention soon ceases to be profitable. Some fruits demand more from the cultivator than others, and the Cherry is a case in point. Everyone has seen old Apple trees that, in spite of being a thicket of guarded branches covered with Moss, continue to bear

good crops of fruit. Roots and branches have been allowed to go their own way for years, and yet the tree bears, and will continue to do so till old age and impaired action destroy it. A Cherry tree neglected in the same way soon becomes an encumbrance, but with the branches kept judiciously thinned, the head of the tree open, and food given to the roots, the Cherry will continue to bear till it becomes a forest tree in size.

Such conditions, however, can only be obtained where the Cherry is at home, and from the reputation Kent has for the fruit, there are some who have an impression that it is a country of Cherries and Hops. Such is not the case, however, and the tract of land which produces the majority of English-grown Cherries is largely composed of brick-earth. Most people associate a brickfield with a mass of wet, cold, heavy clay, where no vegetation grows except rank coarse grass, and about the most unlikely place one could well imagine for growing fruit. Kentish brick-earth is of different composition, being a rich strong loam that will grow either corn, Hops, Potatoes or fruit. Probably one of the finest tracts of land for fruit growing in this country stretches from Chatham to Sittingbourne and the surrounding neighbourhood, and for Cherries it is unsurpassed. Whether brick-making or fruit growing is the more profitable it would be difficult to say, but the industries follow each other in rapid succession and both are lucrative. The fruit grower comes first, and plants bush and standard fruits, including Cherries, which go on for their appointed time. Then the plant of the brick-maker appears in the field, and a depth of from 6 feet to 12 feet of the top soil is converted into bricks. The ground is not a waste after the brick-maker has had his share, as one would naturally suppose, for the fruit grower is close on his heels, and before the whole of the top crust has passed through the kiln, planting is in operation at the other end of the field, and in a few years' time the brickfield is again a smiling orchard. I do not know whether there is any other

district in the country where the soil will first grow fruit, then make bricks, and finally grow fruit again, but such is the case in the locality referred to, and in some of the finest orchards I have seen not only Cherries, but Pears and other fruit occupy the sites of worked-out brick-fields.

Striking indeed is the great contrast between a Cherry orchard, either when in bloom or when the rich red fruit peeps out from a mass of foliage, and the smoky, sulphurous surroundings of a brick-field. Yet they are to be found side by side, and each represents an industry. Here the Cherry is at home, and for miles the orchards stretch away on either side. The brick-making element mars the beauty, but it does not appear to affect the growth of the trees, and the low-lying ground reaching away towards the sea is intersected with creeks, where barges rest on the mud during low tide and are loaded with bricks which they bear away when the water rises, and return in due course deep in the water with the weight of London manure for the use of farmer and fruit grower. London manure is not to be compared with good material from the farmyard, but the fruit grower cannot get the latter, while the former, which serves his purpose on soil so fertile, is readily obtained at a low cost.

Spring and early summer are anxious times for the Cherry grower. Sharp frosts often spread disaster when the trees are in full bloom, and later, when the fruit is set and the grower begins to congratulate himself that the crop is safe, a terrific hailstorm may riddle the tender foliage and send the tiny Cherries to the ground in a hopeless mass. Fortunately, there have been few such complaints this season, and generally crops have been fairly good. Prices also have been satisfactory. Cherries to be lucrative must be grown *en masse*, as birds have a distinct partiality for the luscious fruit, and a solitary tree unguarded would be stripped before the Cherries were fully ripe. From the time the fruit begins to turn a close watch has to be kept in the orchards.

The fruit on many acres of Cherry orchards is annually sold by auction to persons who afterwards pick and market, reaping the profit or suffering the loss, as the case may be. Prices vary according to the quantity or scarcity of the fruit, and it requires no small amount of judgment to form an accurate idea of the state of crops generally and the quantity of fruit in the orchards that passes under the hammer. The Cherry buyer often lays down hundreds of pounds as a speculation at the beginning of the season, and has to pick and market before he can turn his money over. As soon as the fruit is fit for picking, orchards present a busy scene of activity. Long, heavy ladders, broad at the bottom and tapering upwards, are brought into the orchards for the purpose, huge piles of round hampers are placed in readiness, and men, women, and girls with smaller baskets slung on their backs mount the ladders with agility and pick the Cherries with dexterity. It requires experience to place the heavy ladders so as not to break the trees, and one would hardly consider the branches of a Cherry tree to be the right place for women, but much of the picking is done by female labour and accidents are not common. When the fruit has gone and leaves have fallen the ladders are again brought into use, this time for the thinning out and cutting away of dead branches and the setting of things in order for another season. The Kentish Cherries are confined to a few varieties. Early Rivers is being planted in new orchards, and amongst the sorts most largely grown are May Duke, Kent Bigarreau, Napoleon, and Morellos. Varieties bearing local names are also met with.

G. H. H.

CUCUMBER GROWING FOR MARKET.

PLANTING OUT.—Provided plenty of heat is at command, the plants should be ready to put out in the third week from sowing the seed, a good stage for the operation being when the first pair of rough leaves is fairly well developed. Indeed, for all practical purposes it is impossible to err on the side of too early planting, the rapid growth of the Cucumber plant at all times under the best cultural conditions amply repaying any extra exertion to secure this. Now and again, when the previous crop is not over by the time the Cucumbers are ready, I have been compelled to repot into larger pots to partially save the check that must ensue. The actual planting is a very simple affair. See that the soil has been in the house a few days to get thoroughly warmed through, the place perfectly clean. I limewash and fumigate with flowers of sulphur all my houses after each crop. A very good plan, albeit a very old one, in small places is a bed of long manure for bottom heat, this, of course, would need preparing also to dispose of very rank steam and the like. It is not adopted in my case, but a good layer of manure, cow manure preferred for summer crops, is placed throughout the bed at the rate of a load to a 60 feet house, and covered with soil rather firmly beaten. On this the mounds or hillocks of soil are placed, about half a bushel being given to each plant. This and the dressing below will doubtless appear to many too liberal and liable to produce an over-luxuriant growth to the detriment of the crop. Such, however, is not the case; indeed, so small a dressing could scarcely be, and when we remember the depth of manure often given to a single frame for Cucumber growing, it is an open question whether we place sufficient under the plants indoors. Some market growers use none at all, but these either have their hands

continually in the artificial manure bag or have to be satisfied with smaller crops of smaller fruit. The planting merely consists in opening a hole in the mound of soil of sufficient depth for the plant and firming the soil. Cucumber roots travel deeply as well as horizontally with rapidity, and may also be depended upon to descend into any rich food, producing at the same time root fibres in abundance without the necessity of offering encouragement from the burying of the stem. More than this, the plants so buried not infrequently die as a result. With respect to

VENTILATING OR NON-VENTILATING, each grower must decide for himself. If the plant is merely wanted to carry fruit for a given time and then be discarded, the non-ventilating system will answer fairly well, as it does also in those instances where successional batches are planted after the first big flush of fruit is gathered. But where the plants are required to give their maximum of fruit and remain in good condition as long as possible, then ventilate by all means, and that freely, if occasion permits, always, however, by the top ventilators, opening and closing according to circumstances and season. From this time, the

TRAINING OF THE PLANTS must be a matter for daily attention. All laterals that appear close to the ground should be removed, not allowing any within 15 inches of the soil, and push the leader on as rapidly as possible by directing all energy in this direction. Consequent on the space to be covered, the whole of my Vines are allowed to extend the main stem to 7 feet or 8 feet before the point is taken out, this being done as soon as the tip reaches the desired height. While such growth is in progress the laterals extend but little, and quickly spread out when the upward flow of sap is in part arrested. Train the laterals in moderately close to the stem and sufficiently wide apart to allow each to get light and room to develop. The removal of some of the largest leaves from the main Vine will help to accomplish much in this direction. In respect to training the Cucumber, one frequently reads that the fruiting lateral "must be stopped at the first joint after the fruit." There is no gain in this, and the trellis is only encumbered by useless material, which has to be removed later on. A well developed lateral will fruit both at the second and third joint, and in the early stages of the plants it is quite common to be able to count twenty or more fruits showing from the laterals alone. These, however, are always more numerous where the plants have not from some cause or other been allowed to fruit on the main rod. The chief object of the market grower, too, is to cover space only with fruiting wood, and to this end stopping is done at the fruiting joint, *i.e.*, the second fruiting joint from the stem. Where specially fine fruit is needed, the grower here and there may be satisfied with one to each lateral. Of course, many fruits show that do not perfect themselves; indeed, it goes without saying when the lower laterals are crowded with long and heavy fruits that the upper branches with their burden have not much chance. It is just here, however, that the difference between special culture and the ordinary methods become manifest, and most certainly the plant will pay for doing well if at all. An equally important matter is

TOP-DRESSING. The amount of soil already in the hillocks should carry the plants safely till the first show of fruit on the laterals; this, in my experience, is the best time for a liberal addition, placing the bulk between the mounds, as also in front and behind them, the object being to widen the bed rather than increase the

depth of soil. Under no circumstances should the old soil be dry when the new is added, nor should the latter be dry. Top-dressing has a far greater importance than is usually ascribed to it, and too frequently I see plants practically worn out and exhausted because of the mere fragment of soil in which they have been grown. The plants are always much longer-lived if a liberal supply of soil be given from the first show of fruit, and where this principle is followed out the majority of fruit will be of the best quality. It is a stock saying that Cucumbers do not like the roots buried deep in soil, but this truism should not be interpreted to mean that the plants are best when given but a meagre supply. A small supply of soil, which of necessity has to be watered much more frequently than is good for the crop, is mainly responsible for small and crooked fruits; therefore I strongly advocate liberality in this respect, and by extending the bed as above suggested the main roots will still be quite near the surface. In applying these top-dressings, see to it that the soil is kept as nearly level as possible, and not in holes for the water to lie in.

WATERING and damping down, important though these be, can hardly be dealt with here, so much depending not only on the season and the time of year, but equally on the position the plants occupy in the houses. For instance, plants on the soil floor, or only separated by manure, cannot compare with others on a stage 3 feet above the floor, the latter even with a good bed of soil will need constant care and daily watering even in ordinary weather, while those on a solid soil bottom will be kept more moist if watered on alternate days. In places where the raised side stages are employed for this work, I would strongly advise a good thick layer of cow manure 4 inches or 6 inches deep on the stage and made firm as a moisture-holding medium before placing on the soil. This should modify matters a little at any rate.

THE DISEASES AND PESTS attacking the Cucumber are not numerous, if difficult to combat. The worst of them is eel-worm in the soil. Indeed, nothing beyond clearing out and charring the soil and roots will destroy it. This is more troublesome in those instances where Cucumbers have been grown for years in the same houses on the floors; indeed, unless the bottom is made of concrete, there is no way of preventing the roots travelling downwards to the old soil. A dressing of soot and lime will in some measure assist if applied rather fresh before the manure is put in. Green-fly and red spider must be kept in check from the first, as nothing more quickly brings ruin to the plants. These seldom give trouble when a good clean start is made as suggested in the opening of these notes. Occasionally mildew will appear with cold and sunless weather, but by removing the affected leaves and syringing with a solution of sulphur this may be speedily checked. Indifferent ventilating, combined with the above, will also assist to the spread of mildew. Wireworm and woodlice rarely attack more than the young plants, and by a little exertion both are readily destroyed. Woodlice are best attracted to baits of Potato or the like and then destroyed with boiling water.

VARIETIES.—At the present time there are many good varieties, some of the most popular being Rochford's Market, Covent Garden Perfection, All the Year Round, Telegraph Improved, and Matchless, being all good and free. Apart from these are some newer kinds of much promise, of these I am not in a position to speak definitely as to their cropping. Some of the

most handsome fruited kinds, while indispensable for exhibition, are comparatively useless for market work.

MARKETING.—Careful grading is as important as good culture. If possible, send only the prime to market if the latter be at some distance, and distribute the remainder nearer home. In cutting, some care also will be needed, and avoid handling the fruit too much. Packing is equally important, and should be so accomplished that movement is quite impossible in any direction. For packing nothing is better than fresh green grass, used quite clean, first lining the bottom and sides of the hamper, and each layer, as the fruit is placed in position. Of late even more attention has been paid to packing, every fruit being separately wrapped in tissue paper also. Where this is done, good clean hay makes excellent material for filling in and lining sides, &c. With a knowledge of the variety grown, it is easy to arrange the size of the boxes for packing so as to avoid empty and worse than useless space. Boxes or hampers, however, of the following size will accommodate three dozen good fruits, or two and a half dozen selected, the measurements being all in the clear: Depth, 8 inches; width, 15 inches; length, 18 inches.

AVERAGE PRICES.—Quite early in the season, e.g., April, the average price is lower than at the end of May, and frequently June; indeed, I have repeatedly known 2s. per dozen returned in the former and 3s. or 3s. 6d. per dozen in the latter months. Much depends on demand. The best paying months taken over an average of several years are May, June and July, during which prices range from 2s. 6d. to 3s. 6d. per dozen in London markets. Better prices are secured, however, by large firms who have their own salesman and to a large extent their own customers. From the beginning of August onwards lower prices prevail, 2s., 1s. 6d. and even lower per dozen being by no means a remunerative price, even with a big crop to cut, and cost of carriage and commission extra. It is in circumstances such as these that the provincial grower would do well to distribute his fruit locally if possible.

A GROWER FOR MARKET.

ORCHIDS.

DENDROBIUMS.

The majority of this fine genus are essentially spring-flowering Orchids, brightening that part of the year with their chaste and showy blossoms, but there are several fine species and varieties that flower now, and such plants are specially useful where a display is expected throughout the year. Although in many ways the culture of most Dendrobies is similar, there are certain minor details that may be touched on with advantage respecting those kinds now in flower. For instance, where a house is set apart as a Dendrobium house many of the deciduous kinds will by now have perfected their growth, and the temperature and atmospheric moisture must both be reduced. Many others again are beginning to grow, while still another section is in the middle of the growing season. Here much care in arrangement is necessary, and the plants in the warmest end of the house in early summer have to change places with sundry of the Australian kinds now commencing to grow. The deciduous kinds mentioned above will take the sunniest part of the house until quite finished, when it is an advantage to the majority to go into quite a cool, airy, and comparatively dry structure

until the resting season is past, whence they are again taken to the growing quarters. It is not possible, however, to reduce the autumn and late summer-flowering kinds to a section, so much do they vary in their individual requirements, and the purpose of this note will be served more fully by a short description of some of the better-known kinds now in flower or approaching that stage.

D. DEAREI, as an instance, is one of the best known and most useful in the genus, the flowers appearing in the greatest profusion on healthy, well-grown plants, and being, moreover, pure white excepting a slight stain of green on the lip. They last well in good condition, and are, therefore, useful for cutting as well as for decoration on the plant. Position has doubtless a good deal to do with the health or otherwise of this species. I have known it grow well in a house devoted to Cucumbers principally, the strong heat and moisture suiting it well, but for success over a long season a more rational mode must be practised. Heat and moisture are very necessary, and the plants will not thrive without both, but towards the end of the season when the growth is over it needs ripening as much as any of the true deciduous species. Grow it as rapidly as possible from the time the growths start until they are quite finished, and if the plants are taken out during the flowering season keep them from cold draughts as far as practicable. This species was named by Reichenbach after Colonel Deare, who discovered it in the Philippine Islands about 1882.

D. FORMOSUM blooms at various times, but usually in late summer and autumn. It belongs to the nigro-hirsute section, and is one of the finest. Though not exactly a success under cultivation, the immense number of plants imported annually keeps the collections in this country well supplied, and the lovely pure white flowers with golden centre are always looked for. Briefly, it requires an almost unshaded position close to the roof-glass, where heat and moisture are abundant. If grown in pots these should not be large, as the roots will not take freely to a large body of compost. In baskets well drained with plenty of rough, open material they are quite at home, and delight in growing in and out of the rods, where they get the advantage of the sun and the moist atmosphere. In this way immense stems or bulbs are produced, and these with a circle of nearly a dozen large flowers towards the top are very beautiful. Let it have its own way as to growing and resting, but always endeavour, if possible, to let the growths ripen in autumn, and keep the plants at rest afterwards.

D. INFUNDIBULUM is quite a different plant from the last-named, though belonging to the same set. The stem-like pseudo-bulbs in the strongest plants are 2 feet or more in length, but not much thicker than a lead pencil at the base, swelling a little in the centre. The blossoms are very chaste and lovely, pure white, with a dense yellow centre to the lip and more plentifully produced than those of *D. formosum*. This does not like great heat; it is better to grow it with the *Odontoglossums* than in a very high temperature, as in the latter case it is sure to be overrun with insects, black thrips in particular. But the best place, or at least where I have personally had the best results, is close to a ventilator in the coolest part of the Cattleya house. Here it grows to a good length, flowers abundantly, and keeps as well as any of its class to a proper routine of growth and rest. If taken to the cool house at all it should be when at rest. The pretty *D. Jamesianum* is usually supposed to be a variety of this species, and requires if anything cooler treatment than the type. The usually shorter bulbs seem to point to this, and I believe the longer-bulbed varieties, even of *D. Jamesianum*, like a little more warmth and grow more freely than the shorter ones.

D. LERCOLORNUM is not a generally grown species, but a distinct and pretty one. It is of rather large growth and the flowers are small for

the size of the plant. They are produced in longish racemes, are pure white excepting a little green at the base of the lip, and appear in late autumn. It does best in the warmest house, and likes a decided period of rest after flowering. A good deal of care is necessary when the young growths are starting, as they damp off readily, but otherwise it is probably as easily grown as any. It is a native of Malay, and was introduced about 1880.

D. STRATIOTES AND **D. STREBLOCERAS** are singular and not very common Dendrobies, the flowers having curiously twisted petals that at first sight have the appearance of antennae belonging to some large insect rather than a flower. Like the majority of the New Guinea Dendrobiums, these species like a very sunny position and high, moist temperature while growth is going on, careful treatment of the young growths when only a few inches in length, and a decided period of rest when they seem inclined to take it, whether this is in summer or winter. Very similar treatment is enjoyed by *D. d'Albertisi*, the well-known *D. Phala-nopsis*, *D. canaliculatum*, and others, all of which sometimes flower in early autumn.

H. R.

Cattleyas at Rougham.—Though not a very large collection is grown, there are some splendidly cultivated plants in all the better-known species at Rougham Hall, Bury St. Edmunds. The growths are not only remarkably fine in every instance, but clean and in good season. The old *C. labiata* will soon be a splendid show, the immense sheaths now showing being sure to produce a large number of flowers. *C. Bowringiana*, too, is very fine, the light green of the young foliage and bulbs indicating the best of health. *C. Trianae* and *C. Schroederiana* have made splendid bulbs, while *C. Mossie* is not far behind. The plants at Rougham are kept in medium-sized pots, and though not disturbed oftener than necessary, the compost is not allowed to get out of condition before repotting takes place. The temperature is kept well up and the plants are not unduly shaded.

Miltonia Regnelli.—The flowers of *M. Regnelli* are as beautiful as any in the genus, and it is a plant that should be grown by everyone. It helps to keep a bit of colour in the houses in a dull season, and if carefully treated is not difficult to manage. The pseudo-bulbs are 3 inches high, the flowers occurring about four or five together on erect spikes. They are about 3 inches across, the sepals and petals whitish with a tinge of rose in some forms, the lip streaked with deep crimson-purple and white on the margin. It does well on a rafter in a shallow basket suspended from the roof of the Cattleya house, and during the growing season delights in abundant moisture both at the roots and in the atmosphere. Even while at rest no drying off should be practised, but a considerably reduced supply of water is needed. Although discovered by M. Verschaffelt's collector some years before, the first occasion of its flowering under cultivation was in 1855.

Laelia Perrini.—While not quite so showy as some of the *labiata* Cattleyas, this fine old *Laelia* is quite an indispensable plant to the Orchid grower who likes a bit of colour in the houses during the autumn. The species is occasionally imported and often the plants are in a very dirty state when received. They are also badly shrivelled in many cases, but after a thorough cleansing and a few weeks in a warm, moist house they bear quite a different complexion. The plants should commence growing and be thoroughly plump before being potted up, and until roots appear crocks only are best for them. As soon, however, as the first roots can be seen, let them have the benefit of a little Moss and peat; they will then soon establish themselves. Not being quite so strong in growth as many of the Brazilian *Laelias*, care in the earlier stages is required, but there is no peculiar difficulty in its culture. The flowers are very open and well displayed, having rather a flatter appearance than

those of most Orchids. The type has rosy purple sepals and petals, lip deeper, with a yellow centre, and there are not many named forms of it, the most distinct one being *L. P. nivea*, which has whitish sepals and petals and a paler lip than the type.

CYPRIPEDIUM SCHLIMI.

It is a great pity that this, which is certainly one of the prettiest of all *Cypripediums*, is not more generally grown and amenable to culture. The charming little flowers show prettily against the deep green of the foliage when the plants are healthy. The branching spikes produce from six to eight flowers, each about 2 inches across, the sepals and petals pure white with a pink or green tinting just at the point of each, and in some cases a suffusion of purple. The round labellum is white with a blotch of deep rose and a not very open throat. It has been urged that partly owing to this the flowers are fertilised with their own pollen masses in their native haunts, and in consequence what was a strong member of the *Selenipediums* has gradually, owing to self-fertilisation, obtained a weak and impaired constitution. Under cultivation it is certainly not an unqualified success, but sometimes one meets with finely-grown plants. The newly-imported specimens arrive in this country often with a whitish, muddy deposit, as if they had grown in a wet, swampy place, and some growers, taking this as a hint, have grown their plants with a great deal of moisture about them, even going so far as to stand the pots in deep saucers of water. I have seen very fine plants grown in this way, but it is very necessary before allowing all this moisture to see that the plants are well established. To place badly rooted plants into a wet mass of peat or loam will not do, and before anything else endeavour to set up sufficient root action. At first the plants may go into the *Cattleya* house in a shady, moist position, but when they have had a season here and are well rooted they do best in the cool Orchid house or in a shady cool fernery. The compost will vary with the strength of the plants, only a very thin surfacing of peat and Moss sufficing for the first season or two, but after they have got strong, a much heavier compost and more of it will produce a stronger and more vigorous growth. The usual mixture, in fact, as advised for *Cypripediums* may be used and the surface kept below the rim of the pot. One of the most remarkable points about this *Cypripedium* is the fact that it is seldom out of flower, owing to the number of spikes produced and the length of time the individual blooms last. It is a native of New Grenada, and was introduced about 1854.

Masdevallia senilis.—The flowers of this species are very singular in form, and though not so large as those of some of the nearly related kinds, possesses in a remarkable degree that quaint-like appearance so common in the genus. The ground tint of the sepals is a pale primrose spotted with very deep red, and covered with a profusion of white hair-like processes. It is nearly related to *M. Chimera*, and, like it, does best with a little more heat in winter than is usually considered necessary for the more showy flowered kinds. It is a native of New Grenada, and was introduced by Messrs. Hugh Low and Co.

Cattleya Hardyana.—Flowers of this superb *Cattleya*, some of medium quality only, come from several correspondents. In its best forms it is a lovely plant, a natural hybrid between *C. gigas* and *C. aurea*, liking a full *Cattleya* temperature, plenty of light when growing, and a distinct resting season after the flowers are past. It occasionally flowers upon unseasonable growths, but it is far better to keep the plants to the proper routine if possible. When repotting, keep the young growths well back into the centre of the pot or as far as possible, as when the leads grow and root over the sides they are thereby weakened.

Cypripedium ceananthum superbum.—This is one of the best known and finest *Cypripediums*

in the section of hybrids to which it belongs, and a magnificent garden Orchid owing to its splendid constitution. The foliage is deep green, and the tall, erect spikes carry fine, richly-coloured flowers. The upper sepal is a pretty combination of purple, green and white, the petals and pouch deep purple, the former having a yellow area near the base. It should be grown in quantity everywhere, and thrives in almost any description of compost. Some fine plants noted this week were carrying a large number of flowers, having been grown in nothing but top spit loam and a little chopped moss and charcoal. It sounds rather a heavy mixture, but this and many other *Cypripedes* were evidently quite at home in it. In an intermediate house with a reasonable amount of shade and ample moisture it grows well and soon makes a fine specimen. Even where there is no Orchid house many of these hybrid *Cypripediums* may be grown, and capital subjects they are either for cutting or decoration. Their easy culture and freedom of flowering make them especially Orchids for amateurs.

Cypripedium Godefroyæ.—I have noted some very fine forms of this beautiful *Cypripedium* in flower during the week. It is one of the prettiest of all, the foliage as well as flowers being very attractive. The latter are about 2½ inches across, very full, and with broad segments of a clouded white tint freely spotted with deep brownish purple. The culture of *C. Godefroyæ* is similar to that of its allies, *C. bellatulum*, *C. concolor*, and *C. niveum*. Plenty of warmth and moisture is essential, and most growers have found advantage in using limestone in lieu of crocks as drainage or mixed with the compost. There is no doubt that in its native habitat *C. Godefroyæ* is a good deal exposed to the sun and light, much more so than the South American *Selenipedium* section. For this reason the plants should be kept well up in the house, and I have seen plants in bad condition rapidly improve by being placed in small pans and suspended close to the roof glass. Shading, of course, is necessary, as if exposed to the sun under glass the foliage would be ruined, but at the same time the plants must not be overdone with it. *C. Godefroyæ* is named after M. Godefroy, of Argenteuil, who first introduced it about twelve years ago. Its habitat is on one of the many small islands about the Malay Peninsula, where it grows on limestone cliffs.—H.

FLOWER GARDEN.

GENTIANA ACAULIS.

A good deal has been written from time to time concerning the soil requirements of this favourite old garden plant, which is, however, not one of those things that everybody may grow when and in what soil he chooses. Of the actual requirements of the plant, Mr. Wolley-Dod very tersely sums up the whole matter in some recent notes on the genus. This summing up is so essentially true in my own experience, that I am tempted to offer a few remarks in confirmation thereof. In the cultivation of this plant the most essential condition is that of drainage; this is indispensable, and it is a matter of little moment whether the roots are in sandy soil, peat or very light loam. So long as the drainage is attended to, the plant will be more or less a success. It seems, however, most perfectly happy either in light loamy soils overlying gravel or a rather heavier loam overlying red sandstone rock. In these, as well as in peat, the plant flowers most profusely. Of its success in light soils over gravel, I recall the splendid edgings formed of the plant to a great variety of beds of hardy things in the late Mr. Parker's nurseries at Tooting. Here the smallest of bits, single pieces in fact, could be planted as an edging, and form in a couple of

seasons fine flowering tufts that were a sight in themselves. As an edging to Phlox beds the *Gentiana* was always used, and from its position and the very narrow paths—for no particle of space was wasted—the plants were as frequently trampled on as the reverse. Yet all such was borne by the stout leathery leaves with impunity, and in spring the flowering would be as abundant as ever. No care was taken of the plant; it was a success anywhere in these nurseries, and equally so at the adjoining nurseries of Messrs. Rollison. The Tooting district is noted far and wide for its great depth of gravel and light, easily-worked soil. A similar success attends the plant here in the Hampton district, where the soil is rather more loamy than at Tooting. In both instances any amount of gravel may be dug within a couple of feet or so of the surface. Again, in the Chester nurseries the plant is a success, for though the soil is heavier, the plant seems well suited above the red sandstone that is common round about. I remember a long line in the Newton nurseries, as also a large bed and numerous edgings, that always at flowering time were a very fine sight. In the neighbourhood of the Crystal Palace, where the soil is generally more clayey, and in some instances very retentive, growth is not only slow, but meagre, and flowers few and far between. In several districts where a peaty soil obtains success is almost a certainty and the growth rapid and abundant. In a garden near Gloucester where the soil is heavy, cracking badly in summer, and with a subsoil of lias clay, I experimented for years with a considerable variety of additions to the original soil with no better result than formerly. In this garden I have seen tufts nearly a foot across that never produced a single flower doing no better when divided and replanted in fresh positions and soil. In some parts of Buckinghamshire a very similar condition prevails, large and almost flowerless tufts being quite a frequent occurrence. At the same time where the *Gentianella* is a complete success it is among the most delightful of garden plants, and should be made the most of accordingly.

E. J.

Self Carnation Royalty.—This very fine deep bright rose self was raised by Mr. J. S. Hedderley, of Nottingham, an enthusiastic amateur, with whom originated many years ago the fine scarlet-flaked *Carnation Sportsman*, a sport from Admiral Curzon, scarlet bizarre. *Royalty* is of medium height, it produces good grass for layering, the blooms have thick shell-like petals, and the developed flower is full and highly symmetrical, while it does not split its calyx, a common fault with many *Carnations*. It does not appear to have been widely distributed, but I think it deserves a place in the most select lists of selfs for its fine quality.—R. D.

Carnation Garville Gem.—I this season planted out in the open border some plants of this heliotrope-tinted *Carnation* which were bloomed last year, but not layered. When they were planted the longest shoots were pegged down on the surface, with the result that they have flowered abundantly, and the flowers being smaller they have not the coarseness sometimes seen in the case of young plants strongly grown. In addition to Benary's *Theodore*, which does not unfortunately possess a strong constitution, it is, I think, the only other named variety of a heliotrope shade. *Theodore* is not only a flower of fine shape, but it is also very fragrant, but, owing to its delicacy of constitution, few can grow it. On the other hand, *Garville Gem* is of vigorous growth. There is this danger about treating one-year-old plants as I have done: They go to bloom growths and but little grass is produced which can be layered.—R. D.

TOWN GARDENING.

Town gardening—gardening that is in the heart of a city—must always be to a great extent disappointing and unsatisfactory, for the conditions cannot be otherwise than unfavourable and unsuitable. Something, however, can be done, as the accompanying illustrations show, and the dreary monotony of walls can at all events be relieved. Wall gardening seems to offer the best scope for effort in towns, for walls truly are “ever with us,” and rising grimly from flagged areas are rather a despair. The accompanying small illustration gives a suggestion, which was

direction meet with a certain limited degree of success, but in order to derive much satisfaction or enjoyment from them, sedulous cultivation of the habit of thinking about what we have rather than of what we have not is necessary. Nothing is luxuriant in town, and many things perish altogether. Still, most ordinary herbaceous plants, such as Larkspurs, Phloxes, Sea Hollies, and Dornicums, grow and flower: Pinks, Carnations, Irises and Chrysanthemums do well. Tulips, even the rarer species and all the best tall late-flowering ones, also do well. Daffodils thrive very indifferently, and all except

for many years, it is now by no means common. The bulbs of this variety are indistinguishable from those of *L. speciosum* *Kraetzleri*, which are sent here from Japan during the winter months in such huge numbers. Occasional examples of *album novum* crop up among these importations, which, by the way, are usually disposed of as *L. speciosum* *album*. From *Kraetzleri*, which is now pretty well known, *album novum* differs a little in the foliage, which is less pointed, while the flowers are as a rule somewhat larger, more massive, and less regular in outline than those of *Kraetzleri*. In this last the greenish stripe down the centre of each petal is very noticeable, but in *album novum* it is much less pronounced, or altogether wanting. The principal distinguishing feature is the colour of the anthers, which in *Kraetzleri* are chocolate-brown, while in *album novum* they are clear yellow. The blossoms of *s. album novum*, too, open generally a few days before those of *Kraetzleri*. Of the white-flowered varieties of *L. speciosum* the above-mentioned two are among the best, and to these must be added the old *album*, which is largely grown by the Dutch. In this the exterior of the bloom is tinged with chocolate, but the inside is clear white. A variety of this colour, which is, at least as far as I have ever seen it, absolutely worthless, is *album corymbiflorum*, whose irregularly-shaped blossoms are gathered together in a confused jumble. The bulbs, too, split up after flowering much more than those of any other variety. *L. speciosum* in most of its forms is a grand Lily for the open border, but some varieties, particularly this clustered kind just mentioned and the pretty pale-tinted *punctatum*, are not sufficiently robust to flower well in the open ground; hence this last is more adapted for pot culture than as a border Lily.—H. P.

A herbaceous border in a town garden. From a photograph sent by Miss H. M. White, Charleville, Roscrea, Co. Wicklow.

FLOWERS OF THE WANING SUMMER.

THE breath of autumn trembles through the air and again the robin's song is heard. Let us look around before the flowers of summer vanish. *Lilium testaceum* has been lovely. The erect stems rising here and there in groups beside the wide-spreading branches of the old crimson China Roses gave the satisfying upward lines that the eye demands so often in the garden. Especially beautiful were they when, outstripping the garden wall, they reached the background of the distant hill, veiled as it might be in the soft blue haze of morning hours, or clear and deeply blue when rain clouds swept along with sunny gleams between. Their days of prime are over now, but the scarlet Martagon Lilies show brilliantly among the vivid green of the Montbretias just coming into bloom, and so also do the later Gladioli with their bold spikes of glowing colour. A touch of coolness is given by the soft sprays of *Erigeron speciosus* as they fall scattered among the taller leafage. Carnations and Mignonette scent the air. Nothing can well be more delightful than a bowl of these blossoms for indoor fragrance; the exquisite colouring and spicy odour of the Carnations and the all-pervading sweetness of the Mignonette are wholly satisfying, while from out the past comes the fresh light of other days, as their perfume, like an electric spark, touches the memory and recalls the hours and scenes of bygone years.

In the more shaded portion by the pond, Delphiniums, that elsewhere have shed their petals, are still fresh and fair. Growing as they do in ground thick set with other plants, they have used them as kindly supports with the happiest results. In one case the tall stems have passed up through a Crab Apple tree and stand erect, gleaming out through the branches. Another Delphinium has clambered into the tall yellow Scabious, which in turn finds support in the silvery Tree Lupin, and yet another has been caught into a Pampas Grass. These happy accidents, from lack of leisure to bind the stems with branched supports, are very pleasing. Nature in the garden is better left to her own will than given help which is inadequate or destructive to the lines of beauty.

the common stronger sorts seem to die off altogether after the first year or so. Some Lilies succeed, notably white Martagons, which do as well as in the country. Solomon's Seal, *Megaseas* and *Saxifraga peltata* are also good with me.

H. M. W.

Lilium speciosum album novum.—This white-flowered variety of *Lilium speciosum* has been well represented at many exhibitions of late, among others at the meeting of the Royal Horticultural Society on August 9. It is certainly a grand form, but, though grown to a certain extent

originally made to me by my friend Mr. Burbridge, as to one way in which area walls may be clothed. All the plants figured are grown either on flags or in stone pockets, which makes this kind of gardening possible in the humblest back yard. Climbers, such as Ivy, Jessamine, the small-leaved Virginian Creeper and *Muhlenbeckia*, are planted in stone boxes on the area flags, while the pockets on the walls are filled with Irises, Wallflowers, Snapdragons, Pinks, Creeping Jenny, trailing Veronicas and Saxifrages. The larger illustration shows part of a small herbaceous border. Efforts in this

Spiræas are at their best by the water's edge, notably *S. palmata*, with flower-stalks and blossoms of rosy crimson. A poor plant in hot, dry soils, it is here a most attractive one, with profusion of flower and leafage, and passing through the severest winters unharmed. Even when out of bloom it is still interesting, having the crimson stems headed with rosy seed vessels. *Spiræa gigantea* with its bold leafage is a noble plant; its pliant stems, some 8 feet high, toss and sway in the summer wind. It, too, has its roots in the moisture, and its creamy flower-heads show out in fulness against a dark group of Scotch Fir trees rich in the blue-grey tint of their young growth. *Eryngium alpinum* by the water-side has its crown of wild bees clustering round the spiny purple heads of bloom, lying there intoxicated by whatever nectar they extract. Beside the *Eryngium* is *Inula Hookeri*, with its erect flower-stems surmounted by the gold-rayed blossoms.

The Rowan berries are ripening, and when they are scarlet we know that these fair flowers will have passed away; but autumn's hand is bounteous, and holds in store for us wealth of flower and fruit, of colour and fragrance. A. L. L.

FLOWER GARDEN NOTES.

THE much-needed rain came on the 7th, and the flowers are looking brighter and fresher than for a long time. We have been unfortunate in this part of Surrey as to the rainfall, storms that visited other districts having passed us by, and as an outcome of the long-continued drought all moisture-loving plants have suffered considerably. Where facilities for watering do not exist they were losing their foliage. Any *Spiræas* not in a shady position were quite a failure, the spike never emerging from the bud stage; the exception was found in *filipendula*, but the powerful and rambling root action of this variety gives it a great advantage. I was on the point of re-mulching and heavily watering beds of the newer *Phloxes*, or I should have had a very poor display, and this despite the fact that the beds were autumn-planted and both well prepared and mulched. The rain has freshened these up wonderfully, and if the plants are run through to remove the dead pips I shall get plenty of later bloom from the back buds. The large white variety *Snowdon* seems to withstand the drought almost better than any. Of things which a dry season seems to increase rather than diminish the profusion of bloom, as, for instance, *Sisyrinchium* and *Antirrhinum*, it has been noticeable that the flowers were not nearly so long retained, and I have cleared all the earlier spikes from the latter. This, however, having been effected and the rain following closely on the operation, the secondary display will soon be at its best. Tufted *Pansies* have stood their ground well, but watering in their ease was absolutely necessary, and naturally any amount of attention in the removal of dead flowers. Plants from cuttings have certainly done better with me this year than divided stuff.

BRIGHTLY-COLOURED FLOWERS FOR CUTTING.—*Monarda didyma*, more commonly known as *Bergamot*, stands remarkably well when cut. I have a piece before me in a small vase that has been in that position ten days looking as fresh as when it was gathered. It is one of the plants that will flourish in partial shade, and is looking well at present associated with clumps of *Chrysanthemum maximum*. *Dahlias* are doing remarkably well this year. They came early into bloom and are flowering very freely. I have not any of the new varieties, but plenty of bright and attractive flowers are now to hand of *Gloriosa*, *R. Cannell* and *Sidney Hollings*, three good older sorts. On a north-west border *Carnations* in crimson and scarlet still in flower are *Uriah Pike* and *Mephisto*, *Hayes'* *Scarlet* and *Guardsman*. An old favourite, *Murillo*, has done remarkably well this year and supplied a lot of flowers that, although considerably removed perhaps from first-class form, have been good in colour and even

in form, with not the slightest tendency to split. This latter characteristic varies considerably with seasons and situations. Mrs. Reynolds-Hole, for instance, and fancies like *Cardinal Wolsey*, *Goldfinder*, and *Sir B. Seymour* are very fair in some years, and in others will burst the calyx directly the bloom is expanded. I had a variety sent last year from a considerable distance that was certified a non-splitter, but on this soil it is one of the worst offenders. Other bright flowers to hand at the present time are *Gaillardias*, both annual and perennial, and *Godetia Gloriosa*, the latter a decided acquisition and the best of this shade I have seen. Some of the things on which I rely to furnish material for cutting are this year extremely late, for which the dull, cold spring was doubtless responsible.

HARDY FLOWER BORDERS.—The mention earlier in these notes of certain things that in exposed situations are never at their best in a dry summer reminds me to suggest that at this time they may be marked with the view to autumn removal to more favourable sites. Any very common things that may have been planted at the outset to fill in the borders quickly may be similarly noted to be replaced by better things. The preponderance of a particular colour in various parts of the border can be altered, as one of the attractions of such borders is variety as well in colour as in different plants, and this can be effected at the same time that sufficient of each is planted to show it to the best advantage. As the season draws to its close the variety in colour of plants still in flower is considerably lessened, but in summer there is no difficulty in obtaining it. Attention should be constantly given to any plants whose season is naturally short with the view to improve the same by the prompt removal of all dead and decaying flowers, such things for instance as *Sweet Peas*, *Poppies*, and others. The flowering season of some of the newer forms of *Poppy* may be extended through the greater part of the summer given attention of this kind. At the same time, I hardly think it advisable to include them on borders devoted to the best herbaceous plants. The foliage, given a dry time, is apt to take on a brown dingy appearance rather early in the season.

Charmont.

E. BURRELL.

***Campanula lactiflora*.**—This plant is mentioned now nearly every week in the gardening papers, but many correspondents still seem to believe that *C. celtidifolia* is a different plant. The two names, however, are absolutely synonymous, one being, I think, E. Boissier's and the other M. Bieberstein's name, both given independently about the same time to the species, which they found in the Caucasus. The accepted name is given in "Index Kewensis" and the "Kew Handy List of Hardy Plants" as *C. lactiflora*. The colour of the flowers ranges from dark purple, through every paler shade down to white. The average life of the plants is about five years. The self-sown seedlings under favourable conditions produce three or four flowers the first year and grow at most a foot high. The second year they grow to 2 feet or 3 feet and throw up several stalks. The third year they may be considered full grown, and, according to soil and situation, range in my garden from 5 feet to 8 feet high, bearing sometimes as many as thirty large panicles of countless flowers. When soil heaps once become infested with the seed, plants come up in every corner of the garden and sometimes grow up in the middle of evergreens, so as to be ornamental. The great drawback to the species is its frailty, the panicles being broken to pieces by gales if not securely fastened.—C. WOLLEY-DOD, *Edg. Hall, Malpas*.

***Crinum Powellii*.**—For this beautiful hardy *Crinum* we are indebted to the hybridist's skill, it having been obtained by the intercrossing of *Crinum eapense* and *C. Moorei*. It is in every way a far finer plant than *C. eapense*, and is hardier than *C. Moorei*. In order to obtain the best results, the planting of *C. Powellii* should be

thoroughly done, for the huge club-like stems, often a yard or so in length, should be placed at such a depth that fully two-thirds of the stem is below the surface of the soil. The exposed portion of the stem may be covered in the winter with dry leaves, and in this way the bulbs will pass through severe frosts without injury. The long strap-like leaves are so brittle, that rough winds play sad havoc with them; hence, in planting, as sheltered a spot as possible should be chosen. In an angle formed by hothouses or in some such a position, this *Crinum* will succeed perfectly, the additional warmth from close proximity to the heated structures just meeting its requirements. In planting, the soil should be taken out to a good depth (3 feet at least), and the hole re-filled with loam and well-decayed manure, as it is in such a compost as this that we see the *Crinum* at its best. Drainage is necessary to its well-doing, and where the soil is of a clayey nature it is often an advantage to put some bricks or similar material in the bottom of the hole.—T.

BULBS FOR THE FLOWER GARDEN.

AT this time of the year, when the bulb lists fall on us from all parts thick as the leaves in *Vallombrosa*, it may be well to think of the wisdom of avoiding certain errors likely to lead to waste of money and time. It is not only this we have to guard against, but also that people are so much discouraged in this and like ways that they sometimes give up the effort. Perhaps the first most important thing is to avoid things that are not really hardy enough for our country. The difference in the value and production generally of plants that are really fit to take their places in the climate, and come up year after year to remind us of their presence, and those which live only by reason of delicate attentions at some time of the year, such as winter protection, annual planting or sowing, is very great. Although our climate is not one of the fairest in the world, it is wonderful what a number of things are perfectly hardy in it in the way of trees, shrubs, and flowers. It is not merely that we have to guard against difficulties of climate; but in many cases there is a distinct unfitness of soil apart altogether from geographical position. It is quite common to see things doing better in Norfolk, for instance, than in Sussex, owing to the influence of lighter and warmer soils. The *Tiger Flower* (*Tigridia*), for example, is easily grown in many parts where there is fine warm soil, yet it is almost useless to attempt to grow it in many parts of the country. In Ireland the common *Crown Anemone* of the Riviera and Southern Europe generally is quite hardy, and, owing to the warm friable limestone soils in the coast districts, it is possible to grow it almost as freely as a native plant; whilst in cool places and heavy soils it is useless to plant it, and if we do plant it, it soon dies out. The same is true of the beautiful *Ranunculi*. They are not hardy in Britain generally without special care in late planting and protection. We have no doubt that in the coldest parts, if one took care to protect these beautiful *Persian Ranunculi* and plant them at the right moment, they could be successfully grown, but that would mean a great addition to the labour of a place. The nobler hardy *Iris*, *Narcissus*, and *Lily* may be left for years in the same place, and we may be sure that, if anything, they will improve if the soil be right. Among the plants we see often in lists, and which are of extremely doubtful value for the country generally, are *Babiana*, *Ixia*, *Sparaxis*, *Ferraria* (save in very warm soils), *Diets*, *Lycoris*, *Milla*, *Cypella*, *Hypoxis*, *Moræa*, *Merendera*, *Oxalis* (as a genus save two or three kinds); and these mainly are useless because our climate and soil are unsuitable for them.

Apart from considerations of unfitness of soil and hardness, it may be well to consider that undue attention is very often given in English gardens to certain other families that are free enough as regards growth. We think *Hyacinths*, which always take the lead in bulb catalogues, are valued out of all due proportion, being stiff and

often ugly, especially out of doors. They are not nearly so good for the outdoor garden as many other plants, and much money is spent on them which might very well be expended on things of more lasting value and finer form. Another family which is found in some Dutch lists in great numbers is the Allium, but, beyond one or two kinds, such as the Naples Allium and *A. roseum*, and a few other kinds which may be useful as curiosities, we fail to see what there is in these Alliums to entitle them to take a place in catalogues to the extent they do. Many of them are quite inferior as garden plants, and nearly all have the evil smell characteristic of the family. *Alstromeria*, a really fine and beautiful family, is extremely difficult to cultivate in cold soils and districts, but delights in limestone and other warm sandy soils.

Even where there is no question of the beauty or hardiness of the plants, as in the Crocus, it is curious how in some places any attempt at naturalisation ends in the plants dying out: in other warm soils, chalk and the like, they take readily even under Beech trees. And we must take such things into account, best judging by results. Where we find a family doing well, the best way is to encourage it, and try other kinds of the same.

little or no meaning with the subject of this note, which in large plants is perhaps among the rarest of hardy perennials. In point of fact, "clumps" of this would be somewhat difficult to secure owing to the formation of the rootstock or tubers. At the same time this does not dispose of the difficulty generally experienced in getting the plant to flower at all, while in some soils the plant simply refuses to grow with any treatment. In British gardens some difficulty attends the culture of this excellent plant. In winter, too, even when a good start has been made with seedlings, it will be found the slugs below ground have made havoc with the crowns, and if the crown is destroyed in the first year there is but little hope after. The best soil for the plant is one that is deep, warm, rich, and well drained, the last a most important item. If seeds have been secured, these should be sown in drills in well drained and manured ground, selecting a spot where there is little fear of disturbance for a couple of years. Sow the seeds rather thinly and allow the young plants to make two seasons' growth without disturbance, finally transplanting them in the end of March to very rich and light ground. During the winter there is very little to be seen of the plants, so completely do they go

course, it is much less effective. All the individuals of this variety are by no means of equal merit, some having the crimson band far more clearly defined than others. In the very richest form, to which the name of *crinatum* has been applied, the numerous spots are also of a deep crimson tint. In direct contrast to the preceding we have the variety *virginale*, or *Wittei*, in which the flower is of a pure unspotted white, with the exception of a golden stripe down the centre of each segment. It is extremely chaste and beautiful, and is by many preferred to the crimson banded variety, but the two are really so distinct from each other that no comparison can be drawn between them. In one respect at least *virginale* claims superiority, and that is, the blossoms remain in an effective condition longer than in the other. The third variety to be mentioned is *platyphyllum*, which is altogether a more vigorous plant than the typical *L. auratum*. Besides its more robust and taller growth, as well as the increased width of the leaves from whence the varietal name is derived, this also differs in the flower, which is larger, more massive, and a good deal shallower than that of the type. All of these varieties are imported from Japan during the winter months, and as a rule they realise good prices. The bulbs of *platyphyllum* differ from those of the common *L. auratum* in being larger and with broader and more massive scales of a yellow tinge. On the other hand, those of *rubro-vittatum* and *virginale* are comparatively small, but even then they flower well.—H. P.

Wall gardening. From a photograph sent by Miss H. M. White, Charleville, Roscrea, Wicklow. (See p. 157.)

Of Snowdrops, for example—where they thrive, and they by no means thrive everywhere—it would be right to try the many new forms, sometimes called species. So again the Lilies, of the beauty of which there is no doubt, and which, with few exceptions, are hardy. They are faneiful about soil. The rosy and white forms of *L. speciosum*, for example, however well treated, very often dwindle away in some stiff soils, blooming the first year or two, and then—perhaps assisted by the too common disease in some way—one stem only is seen where a dozen used to be, and, finally, the plants die out altogether. In other soils, small plants thrive and rapidly increase, many Lilies taking much more freely to warm, light soils, or soils which have much leaf-mould and peat in them. Where the natural soil is of this nature, it should encourage us to give a fair trial to the many Lilies now in our garden flora.—Field.

Asclepias tuberosa.—This is both one of the showiest and one of the most uncommon of good hardy perennials. What in many instances may be termed large established clumps can have

to rest and so little do the tubers develop till about the third year. With age and given rich and deep soil, there is a tendency on the part of the roots to descend deeply into the earth; therefore, they should not be much buried when planting. Eight or a dozen seedlings will form a group 2 feet or 2½ feet across, and by giving a warm, sunny exposure and specially preparing places in this way a much greater share of success may be secured.—E. J.

Distinct varieties of *Lilium auratum*.—The golden-rayed Lily of Japan is represented in our gardens by innumerable forms, but it is only to a few of the most distinct that varietal names have been applied. In this respect it differs altogether from *Lilium longiflorum* with its long list of varieties, between many of which there is little, if any, difference. Still, there are a few clearly defined varieties of *L. auratum*, one of the most striking of which is *rubro-vittatum*, in which there is a broad crimson stripe up the middle of each segment. When first opened the blossoms of this are remarkably bright and showy, but the coloured portion soon loses its brightness and becomes more of a brownish hue, when, of

NOTES ON HARDY PLANTS.

Jasione perennis.—This is worth more attention than it seems to have. I cannot say how long it is since I saw it especially so fine and bright as this year. It is a low grassy plant with a long thin stem surmounted with flowers suggesting those of the bright and beautiful annual *Centaurea cyanus*.

Dianthus Atkinsoni.—For many years now I have mentioned this plant, and be it understood this identical plant. There are some who still insist that it is not a perennial variety. My one specimen plant, now so full of flowers, and more brilliant than even the Poppies, is no less vigorous than ever, and in the identical place where it has flowered for a long series of summers. It is not more than 1½ feet across, but it might have been much larger had it not been cut and culled from for cuttings every autumn. It proves infinitely more easy to grow and propagate in this garden than the fine double-flowered *Napoleon III*.

Inula ensifolia.—This is the most desirable of all its tribe that I know for the rock garden. There is a neatness about the whole plant which, when in flower, is but 9 inches high. It is rigid and flowers a long time, and is without the running root habit common to some of its genus.

Teucrium pyrenaicum.—I find this very charming alpine plant more often met with in trade and other catalogues than as a flourishing garden plant. It would not matter so much were it not one of the most distinct and lovely of all the things we get from alpine habitats. Just now it is flowering at 2 inches high, the white and purple flowers nestling in congested whorls of bract-like foliage, and the lower parts of the proeumbent stems are closely furnished with almost round, crenate, wrinkled, and deep green shining leaves. The effect of the herbage just now is almost that of a rosette form. I fancy the reason it is scarce may be that young stock is exceedingly hard to keep through the first winter. I have no difficulty in getting nice rooted twigs in the autumn, but nearly all go off both in the open and in cold frames in winter. I feel sure that neither the coldness nor the changeableness of our climate can be the cause. I have reason to believe the remedy for this will prove to be in taking off-sets with pieces of two-year-old root-stems.

Gerbera Kunzeana.—Can anyone say if this differs much from or is identical with *G. lanugi-*

nosa? My plants coming on from seed cannot so far be distinguished from those of *G. lanuginosa*, which I know well, and know it to be a perfectly hardy species, though the curious flowers are but indifferent judged by the standard of beauty of the better-known *G. Jamesoni*.

Pheasant Grass (*Apera arundinacea*).—This beautiful grass is worth growing at any cost, but the fact that in the place where I stood out flowering plants last summer there is now a lot of self-sown seedlings may furnish a hint as to the hardness of the species.

Campanula pulloides is one of the pretty things raised in the gardens at Coombe-shaere by Mr. Archer-Hind, by whose kindness I had a plant two years ago. It comes in, as indicated by its name, somewhere near pulla, and suggests itself as belonging to the tribe embracing such hybrids as *G. F. Wilson*, *turbinata*, and other forms of *carpathica*. The features distinguishing it are chiefly the deep purple colour of its numerous bells and its lateness. The plant is only 3 inches or 4 inches high, and of a pretty tufted habit, the foliage larger and rounder than in *C. pulla*, and more after the *carpathica* style. Though not over vigorous, it is much more so than pulla. With me *C. pulla* is but an indifferent perennial.

Hypericum olympicum.—This is one of the dwarfer shrubby St. John's Worts, only having a stature of a foot or so; its terminal flowers are remarkable for their great size and beauty. A note should be made of this plant for the warmer nooks of rockwork. J. Wood.

Woodville, Kirkstall.

TIGER LILIES.

IN most places the Tiger Lilies are rather later than usual, but are none the less welcome on that account, supplying as they do a colour which is but little represented among plants in flower. There are several forms of the Tiger Lily in our gardens, and the one that is now in most general cultivation is the variety *splendens* or *Leopoldi*, which differs in many well-marked features from the typical *Lilium tigrinum*. The principal items of difference from an ornamental point of view are the larger and brighter coloured blossoms, and the fact that the foliage is as a rule retained in better condition than in the other forms of the Tiger Lily. The spots on the petals, too, are larger than in any of the others. Besides these we have the double-flowered variety, which at one time was thought highly of, and it still remains as the best example of a double-flowered Lily in our gardens. Still for all that it is not (at least, from my point of view) nearly so beautiful as the single forms. The variety *Fortunei* is extremely woolly in all stages of growth, and its flowers are rather lighter coloured than those of the others. Enormous bulbs of this variety are sent here from Japan during the winter months, and favourably situated they push up a very strong stem, crowned by a large pyramidal-shaped head of blossom. These varieties of the Tiger Lily vary somewhat in their season of blooming, the first to open being the typical kind, then the double-flowered form, closely followed by *splendens*, and last of all we have the variety *Fortunei*. The bulbs from Japan are much later in flowering than the other varieties, but when *Fortunei* is grown in this country and under the same conditions as the others, it is not far behind them. The Tiger Lily and its several forms may all be regarded as good border Lilies, for they will flower well in ordinary garden soil. On the other hand, they are seldom happy under pot culture, unless it be the variety *splendens*, which proves very amenable to this mode of treatment. They are all perfectly hardy, and succeed well in good sandy loam. T.

NOTES AND QUESTIONS.—FLOWER.

Mentha Requienii.—I should be glad to know if any of your readers have found this plant growing

wild in the British Isles. It is not given as a native plant in Sowerby's "Botany," and in the "English Flower Garden" it is said to be a native of Co-sien. I found it the other day growing in great profusion and luxuriance in a village on the south coast of the county Cork, where, if it is not indigenous, it has established itself in a most extraordinary way. For almost the whole length of the street the stones in the paved gutter were covered with this little Mint.—H. M. W.

Koiphoffia nobilis.—Truly a noble plant, and if only the true form exists under the name, the spikes from established plants will tower away to 7 feet, and even 8 feet and 9 feet high. It is in this way one of the grandest plants for distant effect in the garden, and if judiciously employed where shrubs of a sombre hue are massed, an excellent result will ensue. Carefully utilised in this way there is a wide scope for such telling subjects as this in any good sized garden. In any case it is a splendid subject for planting in isolated groups on the grass, and if at some little distance from the house, the effect when in flower is a brilliant one.

Lavender.—As a market flower for sale in bunches when in full bloom few things are more reliable, as the demand seems always equal, if not in excess of the supply. Fortunately, it grows freely in our light dry soil, and old bushes continue to yield good crops for many years, but when they get old and straggling, they are easily converted into young dwarf bushes again, as even good-sized branches cut off and planted deeply in the soil root freely, and soon form profitable beds again. In private gardens a few good-sized bushes are decidedly ornamental, and the flowers cut and dried when in bloom are always acceptable.—J. G., Gosport.

JULY IN SOUTH DEVON.

THE dry weather of the past month has had a wonderful effect in forwarding and ripening vegetation both in field and garden. Towards the end of July the wheat fields showed a golden tinge, and the Oats were already cut or were in process of being harvested, the reaping-machine, with its revolving rakes and vibrating rattle, taking the place of manual labour in all but the most primitive country districts. At this season of the year the Meadowsweets fill the air with fragrance from where they grow by lane-side and reedy water-course, or stand in battalions among the rough herbage that fringes the neglected orchard, from the boughs of whose patriarch Apple tree the green woodpecker, with undulating flight and scarlet crest aglow, seeks a more secluded retreat in the neighbouring copse, giving vent the while to a peal of strident bird-laughter, the fabled precursor of the rain that refuses to materialise. On the cliffs, earlier in the year bright with the Sea Pinks, there is a purpler glow where the Heather has spread its opulent colouring among the grey-ness of the rocks. From here as evening falls one can here the shrill screaming of the swifts as they sweep with incredible velocity round the buildings of an adjacent village, ere, soaring in circles, they ascend till lost to sight in the clear air. But the music of the spring-tide is past; the cuckoo is no longer vocal; the dawn-chorus is silent; summer has stilled the voices that but lately trilled so tirelessly, and, until another spring arrives, hedgerow and spinney will not again resound with the singing of the birds.

In the garden the *Acanthus* has reared above its noble leafage stately bloom-spikes 6 feet and more in height, *Achillea ptarmica* fl. pl. The Pearl is white with a wealth of rosette-shaped blossoms, while *Acena microphylla* has disclosed its rosy-spined flower-globes over level spaces of the rock garden and in borders where, on account of its lowly growth, it is used as an edging or carpeting plant. In sheltered gardens the African Lilies (*Agapanthus umbellatus*), both blue and white varieties, have borne their handsome umbels, which remain ornamental for some weeks. In gardens where the soil is heavy and damp this plant is rarely a success, as it appears to require a more thorough ripening than is possible in such a situation in order to induce flower-production, while in dry and sunny positions it rarely fails to blossom satisfactorily. The hybrid *Alstroemerias* have been especially attractive, and no one who has not seen the effect produced by

elumps a yard or so in breadth and twice as much in length, in which the varied colours of these beautiful flowers, ranging from rose-crimson to cream, are blended in harmonious association, can form an idea of the decorative value of this section of the *Alstroemeria* family, two or three plants dotted about the border being totally inadequate to produce the striking effect of which they are capable when massed in quantity. They are easily raised from seed sown as soon as ripe, and in the south-west are perfectly hardy, even when planted at as shallow a depth as 3 inches, though it is generally held that their roots should be covered by at least 6 inches or 8 inches of soil. The handsome orange *A. aurantiaca*, which, associated with the metallic-blue *Eryngium Olivarianum* in floral arrangements, presents a charming colour-contrast, has also been in fine bloom, as has *A. psittacina*, while the white *A. pelegina alba* has also flowered in South Devon. The first white blossoms of *Anemone japonica alba* Honoring Jobert are already reminding us that the autumnal days are not far distant, and the Pearly Everlasting (*Antennaria margaritacea*) has produced its white flower-clusters. The blue of *Anchusa italica* was at its brightest during the early days of the month, and the *Anthericum*s have afforded many a slender bloom-spike. Of the St. Bruno's Lilies, the larger variety is a great improvement in the size of its white flowers upon the type, but the latter is very graceful and has a pleasing effect when arranged loosely in flower-vases, while St. Bernard's Lily (*A. Liliago*) bears branched stems of white flowers, which attain a height of 2 feet and are unassumingly attractive. The white Snapdragon (*Antirrhinum*), raised from cuttings of a strain of particular purity of colour, is effective in masses, some old plants being bushes of flower 2 feet high and half as much again in diameter. The *Aquilegias*, though past the zenith of their beauty, were still pleasing at the commencement of the month, and the Sea Pinks or Thrifts (*Armeria*) had not then terminated their flowering season. *Astrantia maxima* has borne its Scabious-like blossoms throughout July, and in many a garden the *Arums* in the proximity of water opened their white spathes in numbers. The *Arundos* have become objects of decorative beauty as the month has progressed, *A. conspicua* sending up its long silver-plumed shafts, whose slender stems curve gracefully outwards, furnishing an example of delicacy of form such as the Pampas Grass (*Cyperium*) with its more rigid stalks cannot provide. In *A. donax*, as well, beauty of form, though of a different character, is expressed, and from the tall straight shafts the long blue-green leaves flutter like lance pennons in the breeze. Very effective is this *Arundo* when standing out among lower-growing subjects against a dark background, and grace of form is also provided by the *Bamboos*, whose foliage has suffered but little during the past mild winter.

In sheltered gardens *Babianas* have been blooming, and the tuberous *Begonias* are, week by week, increasing the mantle of brilliant colour that crowns their quickly-spreading leafage. The tall blossom-spires of the Plume Poppy (*Bocconia cordata*), ivory-white and pale brown, rise on high above the deeply-cut glaucous leaves that adorn the lofty stems, their silvery reverses gleaming as the wind fitfully stirs them. Of *Campanulas* many have been in bloom, including *C. caspitosa* and *C. carpathica* with their white forms, *C. turbinata* and its form known as *C. pelviformis*, which bears wide-spreading lavender flowers, *C. Van Houttei*, *C. garganica*, *C. cenisia*, *C. G. F. Wilson*, *C. Raineri*, *C. punctata*, *C. Waldsteiniana* and many more of the rock garden *Campanulas*; while of the stronger-growing varieties, *C. grandis* and its white form were still in flower during the earlier part of the month, as were the Peach-leaved Bellflower (*C. persicifolia*), its white and double white forms, as well as its large-flowered variety, while *C. latifolia* produced its pendent blooms of white and purple on its vigorous flower-shoots, and towards the end of July the Chimney Cam-

panula (*C. pyramidalis*) began to perfect its tall column of blossom, while the Canterbury Bells (*C. Medium*), where the earlier flowers had been removed as soon as faded, afforded a second crop of showy bloom. *Callirhoe involucrata* and *C. Papaver* have produced their attractive flowers, while the new race of large-flowered Cannas has commenced a brilliant display in many gardens, and the first rose-lake flower-cluster on the handsome noble-leaved *Canna Ehmami* *iridiflora* expanded its drooping blossoms before the end of the month.

Carnations have been very charming in some soils and situations, the self colours being undoubtedly the most satisfactory for effect in the garden. *Celsia cretica* has borne its yellow flowers, and of the *Centaureas*, *C. babylonica*, *C. macrocephala* and *C. montana* have bloomed in the wild garden, while in the border the blue Cornflower (*C. cyanus*) and the Sweet Sultan (*C. moschata*) have formed breadths of blue, white and yellow. *Chelone barbata*, with its tall slender flower-stems strung with orange-red drooping blossoms, has been exceedingly decorative, and *Chrysanthemum maximum grandiflorum*, with larger blossoms and dwarfed foliage than the type, on which it is a great improvement, has been a mass of bloom. The slender white flower racemes of *Cimicifuga racemosa* hang swaying in the breeze. *Clematis Davidiana* has produced its flowers, and *Cosmos bipinnatus* has commenced to expand its single blossoms above its delicate foliage. The white form of the plant is by far the most decorative, and its flowers arrange charmingly with their own leafage. The blue *Convolvulus mauritanicus* and flesh-pink *C. Cneorum* have also been in bloom, and *Coreopsis grandiflora* is still golden with blossom. *Croton capense* has thrown up its tall umbels of large light pink flowers, while the little *Cypella Herberti* has opened a few of its apricot-coloured blossoms, whose form indicates the plant's connection with the *Tigridia* family. Early in the month the tall *Delphinium*s presented a striking appearance, especially the varieties possessing Cambridge-blue flowers, which when backed by evergreens stand out in delightful contrast to their surroundings. Large clumps, consisting of half a hundred or more bloom-spikes, some of them 7 feet or 8 feet in height, are among the most effective plants that can be used for the back of herbaceous borders. The *Cactus Dahlias* have already come into bloom, but have not as yet given more than a hint of the display that they will afford in the succeeding months. *Gloriosa* and *Starfish* are two good scarlets, while *Cycle*, lake-coloured; *Lady Penzance*, yellow; *Matchless*, maroon; and the exquisitely tinted *Delicata* have perfected many a bright blossom. The bright crimson *Dianthus Napoleon III.* makes a spot of vivid colour in rockery and border, and *Dorenicum plantagineum excelsum* *Harpur-Crewe* has still a few golden stars to flaunt, while in the early days of July the *Burning Bush* or *Dittany* (*Dietamous Fraxinella*) was clothed with purple and white densely-flowered bloom-spikes. *Echinops Ritro*, one of the best of the *Globe Thistles*, has perfected its spherical blossoms. The *Rocky Mountain Willow Herb* (*Epilobium obovatum*) bore its rosy flowers, and in marshy spots the common *Willow Herb* (*Epilobium angustifolium*) has been bright with blossom, a space of some three acres beneath a wooded dell being a sheet of rose colour visible from afar. *Erigeron speciosus* has afforded quantities of its lavender, golden-centred stars, and *E. mucronatus* is flowering profusely in all situations.

In the wild garden the white *Foxgloves* have created a delightful picture, their tall spires of bloom rising above the lower-growing vegetation, and standing out in high relief against a background of *Portugal Laurel* and other evergreens. The *Plantain Lilies* have supplemented their handsome foliage by spikes of bell-shaped, pendent blossoms, while great bushes of *Fuchsia Riccartoni* are crimson with countless blossoms. The *Gaillardias* are bright with their red and

gold, and the *Goat's Rues* (*Galega officinalis*), both the mauve type and its white variety, have been covered with their Pea-like blossoms. For indoor decoration each colour is equally valuable, the white forming a charming arrangement when used alone, while the mauve associates pleasingly with light yellow, such as is provided by the *Paris Daisies*. The *Cape Hyacinth* (*Galtonia candicans*) commenced to expand the ivory bells that hang from the tall flower-spike with the closing days of the month, a particularly pleasing effect being obtained where these are seen rising out of an undergrowth of the bright blue *Salvia patens*. The *Partridge Berry* (*Gaultheria procumbens*) in rock gardens is thickly studded with drooping white blossoms, while *Gaura Lindheimeri*, 4 feet in height, has its slender flower-shoots set with rosy-white bloom. The *Gazania*s make a breadth of glowing orange in the morning sunlight, and the scarlet spikes of *Gladiolus brechenleyensis* form spots of vivid colour. Of the *Gentians*, a few infrequent blossoms are still to be found on *G. acaulis*, and *G. asclepiadea*, *G. cruciata* and *G. septemfida* are flowering. *Geranium lanceolatum* and *G. striatum* have been in bloom, as has *G. sanguineum*, while the latter's white variety was in flower at *Coombe-Isaere*. The scarlet of *Genm coccineum* is still present in the garden, but the flower-lace of *Gypsophila paniculata*, less matured than in former seasons, had scarcely reached its most attractive stage by the concluding days of the month. The annual *Sunflowers* lit their wide brown discs in company with the stately spires of the *Hollyhocks* from many a cottage garden plot, and the earliest of the perennial *Sunflowers* have unfolded their golden blossoms. Old plants of *Heliotrope* that in sheltered spots have passed through the winter unharmed are odorous with blossom. *Helenium pumilum* is yellow with flower, while of the *Day Lilies*, *Hemerocallis fulva*, *H. Kwanso*, and its handsome variegated variety, as well as the new large-flowered *H. aurantiaca major*, have been in bloom, and *Hydrangeas*, both of the *paniculata* and *Hortensia* species, are daily enlarging their miniature blossoms. The common *St. John's Wort* (*Hypericum calycinum*) has covered a steep bank of poor soil with its golden flowers, and *H. Moserianum* is in good bloom, growing into a large bush in some seaside gardens in the south-west. *Indigofera floribunda* has borne its pink flower-racemes in sheltered situations where, early in July, *Ixias* and *Sparaxis* were to be seen in flower. *Inula glandulosa* has produced its narrow-rayed orange stars, and the coarse-growing *I. Helenium* has a good effect in corners of the garden where its vigour will not interfere with less robust subjects. *Iris orientalis* has thrown up tall spikes of white and yellow blossoms, but *I. aurea* and *I. Monnierii* did not extend their blooming period into July. The sweetly-scented *Jaborosa integrifolia* was in flower early in the month, and the *Kniphofias* perfected their brilliant spear-heads of bloom, the sulphur-coloured *K. Laevis* bearing flowers of a charming tint. The *Everlasting Pea* (*Lathyrus latifolius*) is a favourite with the cottager, and makes a pretty picture rambling through a fence or up a trellis, the white variety being also valuable for providing cut flowers. *Lavatera trimestris*, white, pink, and red, is also in great request for indoor decoration, lasting in water for a considerable period if the flower-sprays are cut before the blossoms are fully expanded. In the garden these flowers are very ornamental, growing to a height of 3 feet and bearing a great number of large flowers, which render the plants objects of beauty for some weeks.

Of *Lilies*, *L. candidum* has been generally satisfactory in the neighbourhood this season, few cases of the disease having come under my notice. *L. excelsum* (or *testaceum*) has been exceptionally fine, as has *L. Humboldtii*. *L. Martagon* and the attractive *L. Martagon album* have also bloomed well, as has the old *Orange Lily* (*L. croceum*), this having attained a height of 7 feet in rich soil, where it has been undisturbed for some years. The *Swamp Lilies*, *L. canadense*, *L. par-*

dalinum, and *L. superbum*, have bloomed, though the *Panther Lilies* have not thrown up such vigorous stems or produced as numerous blossoms as they did last year. *L. auratum* has done well in some gardens, bulbs that have been undisturbed for two years having furnished flower-stems over 6 feet in height, while I have seen several specimens of *L. Hansoni* in flower. In the rock garden *Linaria repens alba* has been blossoming, the light blue *Linum narbonneense* and the golden *L. flavum* and *L. arboreum* have been in flower, and *Lindelia spectabilis* has produced its purple flower-clusters, while the vivid scarlet *Lycnis chalcidonica*, *L. Haageana*, and the double white *L. vespertina* have also been in bloom. The early green leaved variety of *Lobelia cardinalis* has produced its vermilion flower-spike, and by the waterside the *Loosestrife* (*Lythrum*) has been bright with colour. The *Musk Mallow* (*Malva moschata*) has been white with faintly-scented blossoms, and the Fern-leaved *Matricaria inodora* fl. pl. has commenced to bloom, while the *Night-scented Stock* (*Matthiola bicornis*) and the *Mignonette*, two sweetly-perfumed flowers, have dowered the garden with their odours. On hot banks of light soil near the sea the *Mesembryanthemums* have made a brilliancy, and along the edges of the streamlet the *Mimulus* has spread a line of crimson and gold, while in the gardens where old-fashioned flowers find favour the *Bergamot* (*Monarda didyma*) has perfected its deep red flower-heads. The scented *Tobacco plant* (*Nicotiana affinis*), although not particularly attractive during the daytime, wakes to beauty and sweetness with the coming of the twilight hours. From its feathery foliage the pale blue flowers of *Love-in-a-mist* (*Nigella*) look out. Many of the evening *Primroses* have been in bloom, among these being *E. fruticosa*, *E. Youngi*, *E. speciosa*, *E. Lunarekiana*, *E. macrocarpa*, *E. marginata*, and *E. pumila*, while *Oxalis floribunda rosea* still made a bright patch of colour in the sunshine during the early portion of the month. The *Tufted Pansties* provide the garden with an abundance of soft colours, which may be utilised with pleasing effect either in the level border or for draping rockery and wall with a mantle of delicate tints. Among the numerous varieties now in commerce it is difficult to discriminate, but the lavender-blue *Ariel* and *Sweet Lavender*, the violet and lavender *Cottage Maid*, the lilac-blue *Florizel*, the blue *Blue Gown*, the yellow *Bullion*, the cream-white *Sylvia* and *Countess of Hopetoun*, and the delicately shaded *Border Witch* are good in their respective hues. The *Paris Daisies*, yellow and white, have been very decorative, many of the old plants being bushes 5 feet and 6 feet in diameter. The *Ivy-leaved Pelargoniums*, from the same cause, that of having passed through the winter unscathed, are particularly effective at the present time, and the other day I saw in a sheltered village the front wall of a thatched cottage covered to a height of over 6 feet with *Mme. Crousse* *Pelargonium*, a mass of salmon-pink blossoms, a novel and beautiful sight. *Pentstemons* are also in bloom, as are the herbaceous *Phloxes*, and *Phygelis eupensis* has produced its scarlet flower racemes, while *Platycodon Mariesi* and *P. grandiflorum* have blossomed well, and *Jacob's Ladder* (*Polemonium*) and the dwarf pink *Polygonum capitatum* have been flowering. Among the *Poppies*, the *Oriental*, *Ice-land*, *Welsh*, *Opium* and *Shirley* have been in evidence, while large plants of the apricot buff *P. pilosum* have presented a delicate colour effect during the morning hours ere the fragile petals dropped beneath the influence of the midday sun, while the *Pyrethrums* have been bright with bloom. *Ranunculus acris* fl. pl. produced its golden blossoms, while the *Fair Maids of France* (*R. aconitifolius* fl. pl.) and the old double *Rockets*, the last one of the most sweetly perfumed of our garden flowers, have been in bloom, while the *Californian Poppy* (*Romneya Coulteri*) is flowered well in many gardens. Some of the blossoms have exceeded 7 inches in diameter, and I lately saw a plant 10 feet in height, its shoots covered with expanded flowers and buds. The *Roses* were at

their best in the early days of July, when Teas and Hybrid Perpetuals yielded baskets full of blooms for the house, and the single white Macartney commenced its long-flowering season. Rudbeckia purpurea has been flowering, and R. Newmani opened its first blooms before the close of the month. The Salpiglossis, with its hues of shot silk, that now brightens the border with its rich colouring, is an annual well worthy of cultivation, as is the scarlet Zinnia for the brilliancy of its colour. Scabiosa caucasica, S. lutea, Silene alpestris, Solidago virgaurea nana, Senecio pulcher, Sweet Sultan, and Sweet William, as well as Sweet Peas, delightful in their faint colour gradations, have brightened the garden with their blossoms, while on the rocky Scutellaria alpina and Sedum album have flowered.

Of the herbaceous Spiræas, S. Aruncus, S. japonica, S. palmata, S. venusta, S. filipendula, and S. gigantea have been in bloom. The Tigridias have provided a most gorgeous display, the scarlet, yellow, rose-coloured, white with spotted centre, and pure white being grown together. In the wild garden Telekia speciosa has bloomed, as did Thalictrum aquilegifolium early in the month, while Tradescantia virginica, Trollius, and Tunica Saxifraga are also July bloomers, as is Veronica Lyalli, and Verbascum phoeniceum was in flower during its early days, while towards its close the Yuccas were throwing up their creamy flower-spikes. Where the presence of water admits of the culture of Nymphæas many of the beautiful newer varieties have starred the pool with blossoms, white, flesh-coloured, yellow, and rose. In a garden that I visited towards the end of the month I noticed a fine plant of the Killarney Fern, apparently in the best of health, growing in a thoughtfully-constructed cave, through which trickling water, entering at the roof, found its way down the sides and out through a channel in the base. In Mr. Archer-Hind's garden at Coombefishacre I saw in bloom Brodiaea californica alba and B. laxa, Codonopsis ovata, with pretty French grey, bell-shaped flowers, but possessing a most unpleasant smell when plucked; Desmodium penduliflorum, Hypericum olympicum, Malva lateritia and M. Munroana, Modiola geranioides, the white Ostrowskia magnifica, Prunella grandiflora, the double white and double pink Brambles, Rosa macrantha, R. moschata nivea, and the R. moschata known as nepalensis. Gerbera Jamesoni had bloomed, as had Incarvillea Delavayi.

Amongst flowering climbers the Clematis family has provided some of the most attractive examples, Lucie Lemoine, Miss Bateman, Gloire de St. Julien, and Fairy Queen, with its pink band, being fine light-coloured varieties, while the rich purple of C. Jackmani is unrivalled among the darker tints. Cobæa scandens, which was not injured during the winter, was in fine flower, as were Honeysuckle and the scented Jasmine, while the yellow-flowered J. revolutum was also in bloom. The scarlet and yellow Mina lobata in some cases survived the winter, as did large plants of Tropæolum Lobbianum, when they provided an early display of brilliance. Another climber that profited by the mildness of the winter was Solanum jasminoides, whose expanse early in the month was smothered in white flower-clusters. The Passion Flowers and Physianthus albens were also blossoming, as were Tropæolum speciosum and T. canariense. Of shrubs and trees Abutilon vexillarium was in full flower, and the common Barberry yellow with blossom. The Strawberry tree (Benthamia fragifera) early in July was a cloud of pale yellow. Ceanothus, Cistus and Cytisus were in flower, as were the double Deutzia and Desfontainea spinosa. Fabiana imbricata, Kalmias and Myrtles blossomed. Olearia Haasti commenced its abundant flowering, and in a sheltered spot an Oleander expanded its rose-pink blooms. Ozothamnus thyrsoideus was thickly covered to the end of each spray with minute white flowers, and the New Zealand Flax (Phormium tenax) was in many cases throwing up its tall flower-stems. The Smoke Bush (Rhus Cotinus) commenced to perfect its feathery in-

florescence, and of the shrubby Spiræas, S. arifolia, S. Bumalda Anthony Waterer, S. flagelliformis, and S. Lindleyana were in bloom, as were the Weigelas, and the standard Magnolia grandiflora on some days showed as many as a dozen ivory-white chalice open at one time.

KITCHEN GARDEN.

BET AND CARROT SOWING.

THE folly of sowing garden Beet too early is likely to be shown again this year, for growth has been rapid, and already I have seen breadths of roots big enough to pass as fair samples of Mangolds, but useless for salads or for cooking. Not only are such roots too big to be placed whole into any ordinary cooking utensil, but the quality also becomes impaired when the roots are so overgrown. Of course seasons vary, and coarse roots do not always follow early sowing, but it happens so now and then and too often to make early sowings reliable. It is far better practice to sow early a few rows for early use and to confine the main crop to a later sowing made in May. Turnip-rooted Beets are in favour in some places, but not here, and I have to bridge the season with the long-rooted varieties. To this end I find it necessary to make three sowings, but the first simply consists of two or three rows; the other two sowings are divided equally, and it frequently happens that the last is the best, roots from this keeping admirably in a cool store until the earliest next year are quite fit. Turning to Carrots, it is pleasing to find that the old-fashioned one-crop system, with its plethora of big and maggot-eaten roots, is dying or being driven out of use. Like early Beets, early Carrots are a necessity, but very little room need be devoted to them, as far better results are had from successional sowings, and an especial argument for the practice is that the bulk of the necessary roots may be grown on ground that has already carried a crop. Where quality and tenderness are requisite, big Carrots are not to be compared to small ones, and this makes it possible to sow in succession right up to the end of July, and even later, with a certainty of getting a satisfactory crop. The last sown may be left in the ground all winter and drawn from as required, as they will develop no core to speak of even if left growing till quite late in spring. For most purposes short Carrots are the best, and some favoured varieties of these should be the only ones sown for late work. Ground cleared of Potatoes or any early crop may be forked over, drilled and sown without any delay, as there will be no bother in digging in manure for Carrots. They do much better without it.

J. C. TALLACK.

Tomato Hathaway's Excelsior.—In these days there are so many so-called new Tomatoes, all claiming to be the best, that one hardly expects to see such an old favourite as this grown. I used to grow this kind largely, and I was pleased to see it again doing well in a low lean-to house at Dillington Park, near Ilminster. It was at the end of June when I saw it, and at that time the plants were 7 feet or 8 feet high and literally covered with bright even-sized fruit. They were growing in Seakale pots in loam and old mortar rubbish.—DORSET.

Tomato Carter's Outdoor.—To those who are dependent on outdoor-grown Tomatoes for the bulk of their crop I can strongly recommend Carter's Outdoor, as being the earliest to ripen out of many now being tested. One or two small-fruited varieties are equally early, but these scarcely form a fair test, and would not be suit-

able for growing in bulk. The one in question is a heavy cropper and the fruits are above medium size, but not so big as some of the selected forms of the Perfection type, such as Duke of York. Its worst fault is that the fruits are very much corrugated, but this may be forgiven, as the quality is excellent, and the season advanced by at least a couple of weeks by its use, a great gain when we consider how short the outdoor Tomato season really is.—J. C. T.

Notes on early Potatoes.—The hot, dry weather of the past week has had a very visible effect on the haulm of the early varieties of Potatoes, which has turned quite yellow, and now lies flat on the ridges and is dying off quickly. The tubers are also ripening fast, but so long as the weather continues dry they are quite safe. Should rain, however, fall in sufficient quantity to moisten the soil before they are ripe, lifting will have to be done at once, otherwise second growth will result. The crop is a good one, the tubers being clean and quite large enough for all ordinary purposes, and the quality is also good. As has already been mentioned in these columns, Famous has given extremely satisfactory results this season. English Beauty has also again exhibited its superiority as a very early kind and has produced an excellent crop. Sharpe's Victor, Myatt's, and Hammersmith are too well known to need comment, while Mona's Pride and Colis's Favourite are excellent. Among the round varieties Early Regent and Boston Quantity and Quality will soon be fit for lifting, the crops of both being good. Main crop and late kinds look well, but need rain. Field crops are not looking quite so satisfactory as one is in the habit of seeing them at this time of the year; in fact, I saw some a fortnight ago in several localities in a very backward state. These were a long time starting into growth in many instances, and are now no doubt at a standstill from want of rain.—A. W.

GARDEN FLORA.

PLATE 1185.

ROSE MAMAN COCHET.

(WITH A COLOURED PLATE.*)

It is said that Maman Cochet was raised from Catherine Mernet, but many rosarians have rather doubted it. Certainly it has no resemblance in growth to the fine old favourite, neither is it so good for forcing, for its flowers are what florists term too heavy. In the garden on a low wall it is excellent. True it has some faults; for instance, the bad quality of quartered blossoms is one of them. This, however, does not very frequently occur. There is also at times a certain dullness of colour manifest, and the centres of the blossoms are often irregular, as in Jules Finger, but apart from these faults it is a truly splendid Rose. I know of no Tea Rose that has such immense outer petals. These are usually suffused with a lively rose colour, a beautiful contrast to the pink and salmon-yellow of the remainder of the blossom. The form is also very distinct, the centre tapering to quite a sharp point. Already this Rose has many times secured the medal for the best Tea in the show—no mean achievement for a variety only five years of age. Maman Cochet is truly an amateur's Rose, having none of those tricks of sudden weakness too often displayed by some varieties frequently exhibited. It is a free grower, almost as strong as Homère, but with stouter wood. It is very beautiful when grown under glass, but a moderate amount of heat suits it best.

A white sport from Maman Cochet has already

* Drawn for THE GARDEN by A. F. Hayward. Lithographed and printed by J. L. Goffart.

appeared. It resembles The Bride in its lemon whiteness, and there is the same blush-pink shading which is so much admired in this lovely Rose, but the grand petals and form of its parent remain. It is strange that this sport should hail from the United States, the birth-place of The Bride, Bridesmaid, Sunset and The Queen. I have often thought that the immense numbers propagated chiefly from cuttings, and also the strong heat employed in their cultivation, have no small influence in accelerating this freak of Nature.

PHILOMEL.

THE WEEK'S WORK.

OUTDOOR FRUIT.

STRAWBERRIES IN POTS.—After making all due allowance for the lateness of the season in obtaining strong runners so as to finish up the potting, which also was in my own case correspondingly late, the plants are now making up for loss of time. Before this appears in print I hope to have them re-set in their proper quarters for the rest of the season. So far, owing to the hot, parching weather, with an almost complete immunity from showers, and oftentimes a searching east wind, they have been stood pot to pot along the garden walks where a little protection was afforded them. Stood thus the watering could be attended to with more dispatch and with less liability to over-water, whilst damping overhead as the sun left them could be performed quite easily. So far the watering has all been done with a rose upon the water-can, and it will still be continued, at any rate for a few weeks to come. The earliest potted are sending forth their first runners, which in every case should be picked off daily as the watering is being looked to. A word of warning, perhaps, may be appropriate, even with the hot weather, not to over-water the plants, for if this occurs it will frequently check the growth. Although soot was used in the crocking of the pots, a still further precaution will be taken of guarding against the ingress of slugs by applying a good dressing of lime to the ash bed upon which they will stand; salt even will do no harm if it is at hand, as I do not want the Strawberries to root through. In arranging the plants allow as much room as possible, at least 6 inches between each pot and a pathway, by leaving out every seventh row of plants if placed in wide beds, so as to allow space enough for convenient attention. Select for this purpose the most open and exposed position possible without any regard now as to extra labour in watering arising from this cause. The primary object should be a close, sturdy growth, which of itself will be conducive to an early completion of growth. Do not yet be induced to apply any liquid or artificial manures to encourage growth; far better do without these altogether than use them yet or frequently. I have already noted that there is a slight appearance of mildew upon Royal Sovereign. This will have to receive immediate attention by a slight application of sulphur by the sulphur puff, which is better than the older sulphur dredge, as it enables one more easily to reach the under sides of the leaves. The new perpetual-bearing Strawberry St. Joseph is maintaining its character with me. The old stools which were planted out only this spring showed flowers as early as any variety, and the few fruits that were allowed to mature proved of capital flavour, of medium size, and globular in shape. As early runners were the first consideration, I was prompted to sacrifice the first crop. The second crop is now swelling, and in later stages down to spikes just making an appearance. The early runners layered into 2-inch and then potted into 4½-inch pots are now well established. The forwardest of these are now swelling their first fruits, and in nearly every instance spikes are showing, whilst in some cases secondary ones are appearing. The plants possess a capital constitution, being sturdy and close

in growth. So far everything points to its being an acquisition to the Strawberry connoisseur. It should have been added also that the flavour is good. My stock of plants is so far outside, standing upon a hard bottom and well exposed. In my case there is no occasion to hurry them, as I have an abundance of Royal Sovereign to last well through September. This variety has this season beaten Vicomtesse H. de Thury in its autumn-fruited properties. The latter has, however, a fairly good crop, that of the former being really a heavy one of finely coloured, large fruits. Louis Gauthier, although an older variety than St. Joseph (but one not sufficiently well known yet to impart confidence to the majority of growers), has the same property of autumn fruiting, but in this case it proceeds from the runners only; whereas in St. Joseph the old crowns produce an autumn crop as well as the runners. In a recent examination of the runners of Louis Gauthier I noted many of them as producing flower-spikes. These runners will be layered, two into a 4½-inch pot, before this number is in circulation, and every encouragement be given to them to quickly establish themselves. In other seasons they have shown in a similar way, but were not layered into pots, so that it is no chance occurrence at all. As a late mid-season variety in the open it is a heavy cropper of good sub-acid flavour.

ALPINE STRAWBERRIES, as represented by Rouge Ameliore, Belle de Meaux, and Large White, are all bearing profusely now, affording daily pickings for breakfast of delicious, highly-flavoured fruits. These alpine Strawberries are better flavoured from the beginning of August onwards than they are earlier in the season. The young stock of alpiners raised this spring is growing very freely under the treatment already given, the only apprehension being that of their growing so fast as to need another removal before finally planting them in their fruiting beds, for which purpose fully a thousand are needed. Daily attention to watering is given to these, even at the cost of planting them afresh, as any check by drought is a great source of weakness afterwards. A late stock of alpiners is being brought on in pots for the last picking of all. These are now well established in 3-inch pots, being fit for transferring into 4½-inch pots for fruiting at any time. From the time of potting they have been grown in a cold frame on the north side of ainery, somewhat after the same method of treatment as that accorded to the herbaceous Calceolaria. When potted, the soil will consist of at least one-third leaf-soil, the rest being loam, road grit, and a little finely-sifted manure from an old Mushroom bed. When potted, the flower-spikes, of which many are now showing, will be picked off, then afterwards all will be allowed to remain, but the plants will then onwards be stood in a more open spot. This is the first experiment with the alpine Strawberry in pots, the object being that of prolonging the season by ripening them under glass. The results will be recorded later on.

OUTSIDE PLANTATIONS.—The weather so far has not been favourable to the planting, much more to the establishing of new outside plantations this season. Without the aid of a good supply of water, the plants so far will not have made much progress. This points very forcibly to the exclusive use of pot plants for garden planting, even if needed by the thousand. The after results will compensate for the labour of layering into pots. When planting, see that prior to it the ground is well broken up and freely manured, too, if occasion occur. If it be a hard and retentive soil, a second forking over may be necessary before planting. This must, however, depend upon each given case. Select a warm, open border for the first early kinds. For some at least a border sloping towards the south will be a good choice. Later kinds and crops had better be on the flat for fear of drought. Those on sloping borders should at once be slightly mulched. The latest of all the Strawberries should, where practicable, be grown under the shade of a north wall, or at any rate be partially shaded. Note as the latest

kinds: Waterloo, well suited for moist places and wet weather; Latest of All, for dry, gravelly soil and a dry time; Oxonian, a reliable variety on the whole for either purpose, but not always the best as regards quality; and that old, but still excellent late Strawberry Elton Pine, which does well even under the shade of trees. Of early kinds the merits of Royal Sovereign are well known, but from a reliable source I have heard that Leader is even earlier. If so, it will prove an acquisition. A trial should at any rate be given it. For mid-season to late, Gunton Park and Lord Sulfield are excellent varieties. British Queen of course should be included where it is found to thrive, giving it a cool border if possible. In planting take pains to make the plants quite firm. Upon light soils it will be found advisable to tread the ground first and then again after planting, using even then the handle of the trowel to make the soil firm if need be. As regards distance apart, all must depend upon the soil and the variety. In some soils 2 feet between the rows and the same between the plants is sufficient for all but the most robust growers, as Royal Sovereign; whereas in other cases that are conducive to strong growth, another 6 inches or even 1 foot more between the rows will not be any too much. Such medium growers as Latest of All will bear planting triangularly, a plan I have adopted for years in special cases with good results (*i.e.*, three plants to each stool instead of one). Waterloo is another instance of this kind of planting—at least, upon this soil. Watering after planting will pay well, even if it be done by extra labour. Do not, however, unless pushed, use the ground between the Strawberry rows for vegetable crops. In trying new kinds be cautious at first. Try any by all means that are considered of sufficient promise, but do not plant them to such an extent as to supplant others the first season which are known to be depended on from past experience.

HORTUS.

KITCHEN GARDEN.

SPRING LETTUCE.—In the southern parts of the country it is well to sow Lettuce late in August—indeed, September will be none too late for plants to stand the winter. The spring Lettuce is an important crop. In many gardens it is needed in quantity, and no matter how carefully plants are treated when sown in heat, they fail to turn in so soon as those sown in the autumn. Living in the vicinity of large market gardens, I have been surprised to see large breadths of Lettuces early in the spring when there has not been a plant in private gardens. Many can obtain useful hints if they study the means adopted. Many think it is mostly owing to glass that large growers obtain reliable supplies. Glass at certain seasons of the year plays an important part, but not now, and this is the time to make the start, as delay means a weakly plant not able to hold its own in a severe winter. In the north I always sowed the third week in August for keeping through the winter. Many sow on a warm south border. I do not advise doing so, but would recommend the market garden mode of culture—an open quarter, raised beds in heavy land, and sowing sufficiently thin to give each plant room to develop. There is no need to be too niggardly with the room; far better give a bed or beds double the size than cramp the seedlings. In my opinion this is the secret of success, as a well-developed plant may lose a few lower leaves, but the centres are sound, whereas in crowded beds a large portion of the plants is lost by damping after a severe frost. I sow in the open on a border running north and south, and in very severe weather place some boards round the beds and pieces of laths over resting on the edge of the boards, and over these mats and long litter or bracken. I am alive to the necessity of a sheltered border for plants put out in the autumn. Here a south or south-west border will be the best position. The soil for the Lettuce beds will need a little preparation, as the plants have numerous enemies to contend with. I find

burnt refuse with a sprinkling of lime or soot one of the best fertilisers, and in land infested with wireworm I have been obliged to use a small quantity of fine gas-lime before digging. The land if in fairly good order will not need heavy dressings of manure; indeed, I do not advise any, as the seedlings need to be grown as hardy as possible. Manure means a soft leafage, readily injured by frost. In heavy land the soil may be improved by the addition of old mortar rubble, road-scrappings, or anything that will lighten it. A firm bed is necessary to success. If the soil is at all light I roll and tread it before sowing, and by so doing get a slower, but firmer growth. As regards varieties, there are not many suitable for present sowing. Of the Cabbage section, such kinds as Brown Dutch, Lee's Hardy Green, a very fine and reliable variety, and Stanstead Park are good. Daniels' Continuity is a grand summer Lettuce that stood the wet and frost two years ago better than any other kind. Cabbage Lettuces are the most serviceable, as they stand frost well and turn in earlier than the Cos varieties, which are valuable for a succession. One of the best is the Bath or Brown Sugarloaf, very hardy and of good quality. Intermediate Cos is also an excellent variety. This grows close to the soil, and is remarkably hardy, as is the larger Giant Winter Cos.

OTHER SALADS.—Endive sown for early autumn supplies will need generous treatment at this date, as though we have had a little rain, the hot weather experienced since has so dried up the soil, that it will cause a scarcity of good salads unless moisture be given freely. Endive recently sown should be given water freely at sunset, and as the season is now nearly past for sowing, it may be desirable to assist germination by covering the seed beds with mats. Should there be any doubt as to the plants being deficient, another sowing should be made at once, and the bed covered as advised till the plants are through the soil. The Round-leaved Batavian is the best for present sowing. Earlier sowings should be well thinned and watered freely. I mulch between the rows in hot, dry weather. This retains the moisture which is so essential to get good salads. Corn Salad should not be overlooked where salads are needed in quantity. A good sowing now will provide a winter supply. It is quite hardy, and well repays good soil. This may now be sown in rows 1 foot apart, the plants being thinned to half that distance in the row and given ample supplies of moisture. Chicory sown in May will well repay good supplies of liquid manure, as unless moisture is given freely it runs to seed at times. The new Christmas Salad Chicory is a grand addition to this class of plants, as, though not unlike the Witloof in shape, it is of a more delicate flavour. From now to October there is no dearth of good salads, and the autumn and winter supply is apt to be overlooked. Now is a good time to sow autumn Radishes. If sown as soon as we get a good supply of rain these will soon bulb and form crisp roots. Mustard and Cress sown under a north wall will furnish the salad bowl for some time if sown every ten days. Watercress may be had in quantity if grown in a shady place and kept well supplied with water. For years I grew the Erfurt variety under a Medlar tree, sowing regularly in spring. Good results may also be obtained by dividing the roots from May to October.

CUCUMBERS.—I have just planted the early August sown plants. These will supply fruit from October to January. By having fruiting plants at the time named one can spare the winter fruiters, as I have found it is useless to crop the autumn ones hard and expect a full winter crop. Plants are best raised this month for winter cropping, and a great deal depends on their culture. I grow as hard as possible for the next two months, so that, given liberal treatment later, the plants soon give good results. The seed is sown in a frame, sturdy plants are secured, and a low night temperature is maintained, with very little, indeed no heat in the middle of the day other than sun heat. If planting out is adopted,

it will soon be necessary to make up the beds. I rely upon pot culture, as thus there is a dwarfing growth. My best winter Cucumbers are Telegraph, Syon House and Perfection.

TOMATOES.—Plants that have been fruiting freely through the summer will now be getting past their best, and if my note advising a July sowing for a late autumn supply was followed, it may now be advisable to clear out the plants. If the new stock be planted out it will be well to give fresh soil, and only a limited quantity is required, less now than earlier in the season, as root-growth is best restricted. For autumn supplies, a sturdy growth should be obtained from the start, giving ample ventilation, and at night a free current of air should be allowed. With plants a fair size I have left off the sashes at night in hot weather from August to the end of September, and the plants delight in the cool night temperature, growing very strong and setting fruit at every joint. When set it is an easy matter to perfect the fruit by giving more warmth in the autumn and a liberal quantity of food to plants bearing freely. If any old fruiting plants are showing a good crop on the new wood, these will well repay food to swell up the crop. A goodly portion of the old foliage may be cut away to admit light and sun. In dull weather the moisture and food must be given less sparingly.

WINTER TOMATOES.—These, if sown for fruiting as early in the year as possible, should now be potted up and grown as hardy as possible. I sow in cold frames and pot up in the middle of August. Excellent results may be obtained by sowing now, as a fair sized plant may be secured by November. After that date the growth made will be small, and it is not advisable to excite the plants unduly during the midwinter months. If the plants fill a 6-inch pot by the end of October they will winter well on a shelf in a temperature of 50° at night and 5° to 10° higher by day, according to the weather. Up to the time of placing on the shelves I expose the seedlings as much as possible. At night the sashes on the frames are removed, and at the second shift the plants are not given any heat. Plants raised thus are far more profitable than seedlings raised in November or December, and bear far better than cuttings struck in the early autumn. When the plants are potted early in the year they show fruit and mature it, whereas seedlings sown much later are only a few inches high and not strong enough to bear fruit till May. S. M.

FRUIT AND VEGETABLE CROPS.

SOUTHERN.

Dropmore, Bucks.—The Apple crop in this district is considerably below the average, for although trees of some varieties are bearing good crops, others are remarkably thin, and in some instances quite barren. The blossoming was all that could be desired, unless it may be looked upon as too heavy or profuse, and this with the prevailing dryness, accompanied with cold winds, so weakened the trees that they could not perfect a crop of fruit. In many instances where they apparently set well the embryo fruits dropped when swelling should have commenced. Among the few standard trees carrying a crop it is chiefly found to be on those that were fruitless, or nearly so, last year. Dwarf bush trees are rather better cropped, the best being those of Lord Grosvenor, Grenadier, Lord Derby, Worcester Pearmain, Ecklinville Seedling, Bismarck, Stone's Apple, Lane's Prince Albert, Winter Hawthornden, Cox's Orange Pippin, and Ribston. Bramley's Seedling, which has hitherto been a very poor cropper, is also carrying a fair crop this year. Pears are almost a failure, the only variety good alike on walls and bush trees being Williams' Bon Chretien. This has cropped well in all positions. Bush trees of Souvenir du Congrès, Louise Bonne of Jersey, Durondeau, Beurré d'Anjou, and Beurré d'Amis are the only ones

among many that have any crop worthy of mention. Wall trees, excepting the one variety mentioned, are also a failure. Peaches and Nectarines on walls are in all cases, both on south and west aspects, all that could be wished; indeed, very much thinning of the fruits has been necessary. The early varieties are now over, including Waterloo, Early Alexander, and Amsden June; Condor, just now ripe, and other varieties swelling satisfactorily. The trees are healthy and making good growth, although in early stages greenfly was troublesome. The trees have needed heavy applications of water at the roots. I gathered the first dish of Waterloo Peach on July 19 this season, a week later than usual. Plums on walls are well cropped, but standards in the open are generally fruitless. Cherries, including Morellos, in all cases have been good. Bush fruits of all kinds have been plentiful and good, although Black Currants were rather subject to blight, and Raspberries did not last long owing to the drought. Strawberries were very good and abundant, and Nuts of all kinds promise well.—CHAS. HERRIN.

Hackwood Park, Basingstoke.—The promise of a good fruit crop early in the season has hardly been fulfilled. Apples in this district are much under average and very small; a few varieties have good crops. Lord Grosvenor, Lord Sulfield, Warner's King, The Queen, New Hawthornden, King Pippin, and Cox's Orange are the best. Apricots are fair in places, while in others they are a total failure. Pears are much under average; the following sorts have about half a crop: Beurré Diel, Beurré Clairgeau, Winter Nelis, D. du Comice, Easter Beurré, and Glou Morceau. Peaches and Nectarines are a full crop and have had to be thinned severely. Plums are a good average; the never-failing Rivers' Prolific and The Czar have very heavy crops. The best of the others are Victoria, Monarch, Archduke, Prince Englebert, The Sultan, and Transparent Gage. Sweet Cherries are fairly good, but Morellos, which generally do well with me, are almost a failure. Gooseberries, Raspberries, and Currants have all been good. Strawberries are a full crop, especially Royal Sovereign, a variety everyone ought to grow, as it seems adapted for all kinds of soil. Filberts are very plentiful.—J. BOWERMAN.

Yattendon Court, Newbury.—I should consider this a good average year. Of Apples I have a good general crop. Wellington is perhaps the worst crop. I sprayed the Apple, Pear and Plum trees twice with Bordeaux mixture and Paris green, and I consider the spraying in every way effectual. Pears are a thin crop; Plums very good; Currants and Gooseberries good. Strawberries are also good. Raspberries were a good crop, but affected by the drought. Apples on standards in the orchards and cottage gardens are a variable crop; in some cases abundant, in others a failure.

Vegetables are as a rule good. Potatoes are very good and free from disease. Green vegetables have been plentiful, but Peas and French Beans are now getting scarce from want of rain. The rainfall here for the months of July and August up to date (August 11) is just 1 inch.—R. MAHER.

Cassiobury, Watford.—Apples, Pears, Plums, and Cherries are under average; Apricots and Strawberries a good average. There was a fine show of blossom on Apples, Pears, and Plums, but owing to the cold nights all through May and June the trees failed to set a crop.

Vegetable crops in general are well up to the average.—CHAS. DEANE.

Addington, Surrey.—Generally speaking, crops of all kinds are fairly good. Bush fruits, such as Gooseberries, Currants, and Raspberries, are plentiful and of excellent quality. Strawberries are a heavy crop and fine; Plums good; Apples moderate and Pears a poor crop.

Cauliflowers from the autumn sowing I never saw better. The seed was sown on the 24th of August, a portion of the seedlings was potted, and part pricked out into cold frames. The

weather being open and plants strong, they were planted out on the 20th of January, and began to turn in by the middle of May. Early Potatoes, Ashleaf and Sharp's Victor, have turned out good crops of fine healthy tubers. Late kinds so far look promising. We have been very short of rain up till to day (August 6), but have had a good soaking, about 1½ inches. The drought told more upon the Pea crop than any other. — JOHN MATHISON.

Wentworth Gardens, Virginia Water. — I think that on the whole the fruit crop falls somewhat below the average. Apples appear to be over average and good, but have suffered from want of rain to swell them. Pears are a very light crop: Plums under average: Cherries, Morello, under average. There was a good set of fruit, but it fell during the stoning period. Peaches and Nectarines are under average: Apricots a failure. Bush fruit has been good, but Strawberries and Raspberries are only fairly good.

The vegetable crop, considering the nature of the soil and the continual drought, are looking remarkably well. Asparagus has been good and plentiful. Beans, except dwarfs, are good; Cabbages and Cauliflowers very fine. Carrots are poor, being badly attacked with wireworm. Onions are very good. Early Potatoes are good, late kinds suffering from want of rain. Tomatoes look promising. — W. MARCHAM.

Gaddesden Place, Hemel Hempstead. — Strawberries have been a very heavy crop; Raspberries good: Red and Black Currants a good average crop; Plums very thin, almost a failure on north walls; fair crop on south walls. Peaches, Nectarines, and Apricots are good: Cherries, dessert and Morellos, good: Pears poor. Apples are below the average, very much infested with American blight.

Vegetables in general have done well, although they have suffered somewhat from want of rain. Potatoes are not quite so large, but of good quality and very clean. I am afraid the late ones will make a fresh growth should we get a lot of wet now, as they are showing signs of ripening. All the green crops are promising. — HENRY FOLKES.

Barham Court, Maidstone. — The Apple and Pear crops are a very good average; in fact, Pears are better than usual. I find Plums generally a very good even crop. Peaches (outdoors) are very good, but will be very late in ripening. Red and Black Currants are poor; Gooseberries very plentiful. My Strawberry crop has been exceedingly good, but the earliest fruits were injured by a hailstorm which passed over this locality at the time the main blooms were opening. I am here referring to La Grosse Sucrée and Royal Sovereign. I also found Royal Sovereign much damaged by wet. The main crops of Strawberries, Sir J. Paxton, Sir C. Napier, and Waterloo, have been exceedingly useful to me this season. Damsons are fairly good. — HERBERT MORRIS.

Tingrith Manor, Woburn. — Strawberries were good both in quality and quantity. Raspberries are over average and of good quality. Apricots are plentiful and of good quality. Peaches are an average crop, Royal George and Princess of Wales being full crops, while some others are thin, the severe weather when they were in bloom doubtless being responsible. Apples are an average crop and now swelling very fast, Lane's Prince Albert, Peasgood's Nonsuch, Red Astrachan, and Mr. Gladstone being the best. Pears are good. Doyenné du Comice, Louise Bonne of Jersey, Williams' Bon Chrétien, and Jargonelle are loaded. Cherries are an average crop. Red, white, and black Currants are very heavy crops, as also are Gooseberries. Plums are under average, and aphids has been very troublesome. Nuts are under average. — J. HAMMOND.

Luton Hoo, Beds. — In this district Pears and Cherries are slightly under average. Apples, Plums, Peaches, and Nuts are about the average, whilst Apricots are under. Small fruits, such as

Currants, Gooseberries, and Strawberries are a good crop; indeed, I have never had finer Strawberries than this year. Royal Sovereign, Leader, President, and Latest of All are the best of the varieties grown, and ripen in the order named. Monarch appears to be a good useful Strawberry for fine fruits, but the general yield is not so heavy as from the above-mentioned sorts.

Vegetables have been quite up to standard. All are later than in previous years. Turnips have been the most trying crop to grow, which is accounted for from the dryness of the season. Blight has been prevalent. Apples and Plums are the trees most affected, some of the trees being almost denuded of leaves. — GEO. H. MAYCOCK.

The Gardens, Wrest Park, Ampthill. — The fruit crops in the gardens here this season are on the whole very satisfactory, also in the neighbourhood of Ampthill and Silsoe. The cold nights during May and early part of June were not quite so favourable for the fruit crops as might have been desired, and retarded the growth of fruit and vegetables at least from ten to twelve days.

Vegetables have done very well, but some varieties have suffered more or less from the attack of mildew, owing no doubt to the backward state of the weather during May and June. — GEORGE MACKINLAY.

Theobald's Park, Herts. — Apples are very thin, excepting a few trees of Sandringham, Alfriston and Dumelow's Seedling, which are well loaded. Pears are a very good crop, especially on walls. The varieties doing best are Williams' Bon Chrétien, Beurré Superfin, Gregoire Bordillon, Marie Louise, Pitmaston Duchess, Louise Bonne of Jersey, Olivier de Serres, Glou Moreau, Beurré Rance, and Easter Beurré. Plums are an average crop, excepting Green Gages, which are poor. Cherries are an average crop, including early and late varieties. Peaches are very good, the varieties doing best being Alexander, Barrington, Early Beatrice, Early Silver, Grosse Mignonne, Hale's Early and Walburton Admirable. Nectarines, including Elruge, Early Rivers, Hardwicke Seedling, Humboldt and Lord Napier, are good. Of Apricots there is a very poor crop. Strawberries have been excellent, especially Royal Sovereign. Raspberries and other small fruits are an average crop.

All vegetable crops are looking exceedingly well here this season, especially Peas, Beans, Onions, Beetroot, Cauliflowers, and winter greens in variety. — F. W. GALLOP.

Cambridge House, Twickenham. — Fruit and vegetable crops have been very satisfactory, but have suffered from the drought. Cooking Apples, such as Lord Suffield, Warner's King, Ecklinville, Lane's Prince Albert, Cellini, New Hawthornden, Keswick and Manks Codlins, Bismarck, &c., are bearing very heavy crops. Dessert kinds are rather thin, excepting King of Pippins: Apricots above the average and large. Of Pears, Williams', Marie Louise, Jargonelle, Beurré Diel, Beurré Sterckmans, and Louise Bonne of Jersey have very good crops. Of Plums, Green Gage, Orleans, Czar, Jefferson's, Golden Drop, and Victoria are very heavy. Strawberries are very good, but did not last long on account of the dry season. Bush fruits are abundant, excepting Raspberries, which were small. — J. E. BURTON.

Old Warden Park, Biggleswade. — In the early part of the season the prospect of fruit was very encouraging. I never recollect seeing so much bloom on all kinds of fruit trees. Apples are a good average crop; the fruit is very clean, the trees very healthy and making good growth, but the fruit is backward and consequently rather small. Pears generally are a very thin crop, but the trees are clean and healthy and making good growth and the fruit very clean. Plums are very scarce, but the trees generally are free from insects and making good growth. Cherries are a good average crop, but a good deal infested with black fly. Peaches and Nectarines on unprotected walls are clean and healthy, but very

late; crop under average. Apricots are a very thin crop. In the early part of the season the trees were very much infested with a small green grub, but they are now making clean and healthy growth. Small fruits, Gooseberries, Currants, and Raspberries are exceptionally good and plentiful: Strawberries very good and plentiful; over average. I find Laxton's Royal Sovereign one of the best and earliest varieties grown. Latest of All I find a good substitute for British Queen on light sandy soil. — G. R. ALLEN.

EASTERN.

Livermere Park. — Taken as a whole, the fruit crop generally is a very fair one this year, and there are no complete failures. At the same time the early promise of heavy crops all round has not been entirely fulfilled. The exceptionally dull days and cold nights have kept the crops backward, and the rather severe frosts we had for a few nights at the end of April and beginning of May did much damage to tender blossoms. Apples are again above the average, most of the trees being heavily laden with clean fruits. The weevils and grubs generally have not been so much in evidence as last year. Growth on the trees has been till now very slow, and for a time looked very pinched, but the trees are now righting themselves again, and heavy rains, which have prevailed during the past few days, will do them much good, especially if we now get warmer weather. A few varieties are not very satisfactory this year. These include Scarlet Nonpareil, Wyken Pippin, Golden Harvey, Quarrenden, and Keswick Codlin, but such useful varieties as Blenheim Orange, Wellington, Ribston Pippin, Cox's Orange Pippin (for once in a way), King of Tomkins County, Livermere Favourite, Nortolk Beaufin, Cox's Pomona, Bramley's Seedling, Crimson Queening, and many others are heavily laden. Pears are a poor crop all round. A few of the best are Conseiller de la Cour, Marie Louise (very good), Brown Beurré, Knight's Monarch, Beurré Hardy, Williams' Bon Chrétien, Jargonelle, and Duchesse d'Angoulême. The trees suffered much from the biting winds which prevailed soon after they started into growth. Peaches and Nectarines are about the worst outside crop we have. Apricots, on the contrary, are excellent—quite the best crop the trees have borne for eleven years to my knowledge. The fruits now want sun to ripen them. Cherries, sweet and Morello, are under average, but the fruits are good. Plums are almost a failure in the open, but a heavy crop on walls; the blossom in the open was caught by frost and killed, only a few late flowers on the under sides escaping. Strawberries, after showing well, did not come up to expectation; many blossoms failed to set owing to the dull, cold, and wet weather which prevailed just after the flowers opened and which prevented all aid to setting from insect life. Except in the case of Leader, which was very fine and good, old favourites such as President and Latest of All turned out best. Royal Sovereign rotted badly on the plants, both in two-year-old beds and on the south borders as yearlings. Raspberries have been a fine crop, and so, too, have Currants, red, white, and black. Gooseberries suffered from frost while in blossom, but managed to carry a slightly under average crop and the fruits are extra fine this year. Outdoor Figs, generally a precarious crop, are this year very good indeed. There is no hope for the Grapes outside, as the Vines were only just in blossom quite at the end of July. Damsons are a good crop in places where the frost missed them, but this only happened in rare cases. Medlars and Quinces are average crops: Walnuts and Filberts much under average. Tomatoes are very backward, but are carrying plenty of fruit, which only wants sunshine to ripen it. American Blackberries, such as Wilson Junior and Kittatunny, promise heavy crops.

Vegetable crops are mostly good. Potatoes are turning out well, but disease is becoming very prevalent in the haulm, though not much as yet in the tubers. Lifting is being pushed forward with second earlies, as some of these are the worst

affected as yet. Snowdrop was lifted before it took any harm, but Windsor Castle, one of my best Potatoes, has gone down sadly during the recent rains. Of late main crops the least affected is a Potato for which I venture to predict a great future, viz., Syon House Prolific. Last year this was my best late, and I expect it to turn out equally well this year. Celery is fine, though I see much of the maggot in surrounding gardens. Onions are very good, not quite so large as usual, but very sound and firm. Kales generally are looking well, and very little troubled so far by caterpillars. Asparagus was a good crop, though late in appearing; the growth made promises well for next year's crop, and is extra good on young and thinly-planted beds.—J. C. TALLACK.

Ampton, Bury St. Edmunds.—Small fruits are above the average. Strawberries were very fine and of good flavour. Raspberries are an enormous crop. Gooseberries and Currants, although the bushes are laden with fruit, are of fine quality. Plums are a failure, except on walls with a southern aspect; Damsons an average crop. Pears are scarce, though some trees on south walls are carrying a fair crop. Morello Cherries are plentiful. Some May Duke Cherries on a north wall have borne a good crop of fine fruit. Apricots protected with nets until out of danger of spring frosts are an average crop. Figs outside on south wall, having been protected with Braeken in winter, are an average crop.

All vegetable crops are looking well. Potatoes especially are a very heavy crop. I have found a few early tubers diseased. Late Potatoes are free from disease at present. Tomatoes are very late, and I fear will not ripen well.—J. CHILCOTT.

Scawby Hall, Lincoln.—The fruit crops in this neighbourhood are somewhat variable and late in ripening. Strawberries have been a poor crop here, while in other places they have been good. Red, Black and White Currants, Gooseberries and Raspberries are heavy crops. Pears and Plums are light; Apples medium; Apricots light; Cherries medium.

Vegetables have not done well owing to the meagre rainfall. Peas have done well where they have been sown in trenches, but where sown upon the level have suffered from drought. Runner Beans have grown well, but have not set their flowers. Beet, Carrots, Salsify, Parsnips and Onions are small. Early Potatoes are a light crop. Late Potatoes have greatly benefited by recent rains, and have not shown any signs of disease at present.—E. SEMPER.

Uppington House, Stamford.—Strawberries, Raspberries, Gooseberries, Cherries and Currants have been good and of fine quality, but Pears are very poor. Apples are very light crops. Vegetables are very good on the whole.—W. BARKHAM.

Babraham, Cambridge.—Apples here are an average crop, and some kinds very good; amongst the best being Prince Albert, Lord Sulfield, Lord Grosvenor, Grenadier, Peasgood's, Mother, Wealthy, Bismarck, Newton Wonder, Hoary Morning, Baumann's Red Reinette, Golden Noble, Ecklinville, King of Pippins, Tower of Glamis, Warner's King, Golden Spire, Beauty of Bath, Lady Sudeley, and Mr. Gladstone. Many other varieties have a fair amount of good fruit. Blight has been more prevalent than usual, especially amongst Plums, which are very scarce. Out of numerous varieties grown none are worth mention for a crop except Victoria, Early Prolific, and Orleans. On the walls, Early and Late Transparent, Golden Drop, Jefferson's, Reine Claude de Bavay, Washington, and Monarch are carrying good crops. Pears are very thin; Cherries pretty good; Apricots a good crop, also Peaches and Nectarines. Waterloo and Alexander Peaches were ripe in the middle of July. Strawberries have been a good crop. Some of the earliest blooms got spoilt by frost, gathering being a fortnight later than usual, Royal Sovereign being the best. For late use Oxonian has been good. All kinds of Currants have been plentiful and good; Raspberries and

Gooseberries good. Nuts and Quinces are an average crop. The trees looked well when in blossom, but we had some late frosts and very cold winds at the time, and a lot of damage was done to Plums and Pears. The rainfall has been very meagre during the past few years. Our light soil stands much in need of rain to ensure a fruit crop for another year.—J. HILL.

ROSE GARDEN.

ROSA WICHURIANA HYBRIDS.

THE two new hybrid Roses illustrated were raised by Mr. W. A. Manda, of South Orange,

Jersey Beauty (R. Wichuriana × Perle des Jardins) which have proved very useful, not only as trailers and climbers, but as Roses for forcing for Easter. They were called Pink Roumer, South Orange Perfection and Manda's Triumph. The present set is the result of crosses with Teas and Hybrid Teas such as Perle des Jardins, Meteor and others. To my mind the peer of them all in most respects is the one named Gardenia, the result of crossing R. Wichuriana with Perle des Jardins. The long well-shaped buds are bright yellow on the under side, and when expanded the flowers are white, giving the flower the aspect of Gardenia Fortunei—hence the name.

Jersey Beauty (R. Wichuriana × Perle des

Rose Evergreen Gem (R. Wichuriana × Mmc. Hoste). From a photograph sent by Mr. James MacPherson, Trenton, New Jersey, U.S.A.

New Jersey, U.S.A. The complaint was at one time common that scarcely a hardy climbing Rose was available for the Northern States other than Feast's Gem of the Prairies. Now there are several. Two years ago Mr. Manda sent out an initial set of hardy hybrids of

Jardins) is a single flower, with heavy masses of golden anthers and lucid evergreen foliage. Evergreen Gem (R. Wichuriana × Madame Hoste) is a double white flower and a dense, rapid grower. A cross with Meteor has a large flat, double flower of the La France shade of

pink. It is unnamed as yet, but, like all of these *Wichuriana* crosses, is a vigorous grower, and just the subject for planters who desire to cover walls and fences, or without training to cover bare ground along railway cuttings and embankments or anywhere. Like the species, all these hybrids are quite hardy.

JAMES MACPHERSON.

Trenton, N.J., U.S.A.

CLIMBING ROSES IN BUSH FORM.

BECAUSE SOME ROSES are extra vigorous in growth they are catalogued under the heading of climbers, and the uninitiated naturally suppose that a wall or fence is essential for them. But let anyone try them as bushes and he will be pleased with the result. I do not say they should be mingled with the true dwarf-growing Roses, for nothing appears so incongruous as a rampant Rose on the outside of a bed or border and a weak, puny grower in the centre. What I do advise is that these climbers and semi-climbers be grouped together in good bold beds, keeping the extra vigorous kinds in the background. Of course such plants require plenty of space. I do not consider 4 feet apart each way any too much for their proper development. The first season the plants will look somewhat strange, for they are generally supplied from the nursery with shoots ranging from 3 feet to 5 feet in length, and these are in most cases of a very rigid nature. However, the second season all formality disappears as the grand shoots break up from the base of the plants. At pruning time these climbers should be cut down to about 18 inches to 24 inches from the ground, and it will be found that a great number of the new growths will bear flowers at their points. In my opinion these climbers form ideal bushes with their long wavy branches swaying about with their crown of blossom, and in course of time many of the older growths will be induced to produce blossom almost the entire length of the shoot. An important fact to remember is that we have some of the best yellow Roses among these climbers. Of course if one could obtain a *Mme. Hoste* with the colour of *Maréchal Niel*, a superb acquisition would be gained. But until we obtain such an one, we must perforce go to the climbers and semi-climbers for this very valuable colour. All stiffness should be banished from the Rose garden, and this may be best accomplished by employing the less rigid-growing kinds. As standards these climbers make excellent heads, strong, bushy, and spreading. It is surely far better to see a well-developed head of a standard *Gloire de Dijon*, *Mme. Berard*, or *Reine Marie Henriette* than a puny stumpy one of a *Baroness Rothschild* or an *Etienne Levet*. In mentioning a few of the extra vigorous kinds that give good results if treated as described, one must place first the ever-popular *Gloire de Dijon*. Other excellent kinds of the same race are *Mme. Berard*, *Belle Lyonnaise*, *Bouquet d'Or*, *Kaiserin Friedrich*, together with *Duchesse d'Auerstadt*, *Mme. Moreau*, *Germaine de Marest*, *Henriette de Beauveau*, *Mme. B. Levet*, *La Soleil*, *Joseph Bernacchi*, *William Allen Richardson*, *Celine Forestier*, *Pink Rover*, *Souv. de Mme. Joseph Metral*, *Waltham Climber No. 1*, and *Marie Robert*. The semi-climbing kinds are best represented by *Gustave Regis*, *Mme. Pierre Cochet*, *l'Idéal*, *Mme. Eugène Verdier*, *Mme. Chauvry*, *Mme. Jules Siegfried*, *Dr. Rouges*, *Germaine Trochon*, *Mme. Marie Lavallée*, *M. Desir*, *Rosette de la Legion d'Honneur*, *Alister Stella Gray*, and *Mme. Wagram*. Other Roses of other classes suitable for the same mode of

culture are *Robusta*, *Climbing Capt. Christy*, *Gloire de Margottin*, *Bardou Job*, *Gloire des Rosomanes*, *Mrs. Paul*, and *Climbing Souv. de la Malmaison*. P.

ORCHARD AND FRUIT GARDEN.

THE COLOURING OF GRAPES.

VINES with their roots in a suitable medium will produce healthy growth and good-sized bunches and berries annually, but the finishing of these will be considerably influenced by its temperature. It has more than once been observed that the earlier Grapes did not, under certain circumstances, finish so well as did the later lots, and that shanking was also more prevalent among them. Of course this was most noticeable when the Vine roots were in an outside, or had the run of an outside and inside border. The winter's cold and moisture from melted snow would so lower the temperature of the soil surrounding the Vine roots that growth was more likely to be marred than encouraged under this condition. During the first six months of the year the sun's influence cannot penetrate to the depth the roots go, and water is rarely artificially applied to outside borders, consequently there is no effort made to improve the adverse conditions. Twenty years ago this seems to have been better understood than it is at present, for many gardeners then covered their outside Vine borders in autumn with beds of leaves and long litter to the depth of 4 feet to husband the solar heat. Others, instead of using such a huge mass of fermenting materials, would only employ a covering of something like a foot of it, and on this place wooden shutters to prevent cold rains and the snow water getting into the soil. In those days, too, gardeners were very particular about the temperature of the water they supplied to their Vine borders; in fact, some were so much so that it had to be brought up to a certain degree of warmth before a drop was allowed to be used. Under this kind of treatment we invariably had our black Grapes really black, and shanking was almost unknown among them. As time advanced, and money for the garden began to diminish, staffs were reduced, and, in consequence, these aids to successful Grape culture were discarded, or rather neglected. Vines, then, with their roots in outside borders, some of these being scarcely raised above the level of the adjoining ground, and left entirely to the attention of Nature, began to exhibit inability in finishing their crops. Some Vines which were grown under these unfavourable conditions had not a single well-coloured berry in the lot, and shanking was bad amongst them. These were early Vines. Those ripening in August did much better.

By noting these facts and many others connected with the growth of the Vine, I was led to conclude that Vines could be considerably influenced by the use of warm water at their roots. In a house of Grapes just colouring I watered the half of the border with water at a temperature of 90°, and the other half from the ordinary water supply. The Grapes over that portion of the border which had been treated to a dose of warm water finished as if by magic, with not a single shanked berry. Those growing on Vines affected by the water obtained from the ordinary supply (and which stood at 52°) took a considerably longer time to mature, but never got black, and shanking was very bad among them. With this proof of the efficacy of water at a high temperature for not only aiding Grapes to finish well, but also as a

means of reducing shanking to a minimum if not entirely overcoming it, I would strongly advise everyone to give it a trial. Although I have only mentioned using hot water for finishing Grapes, I think it ought to be employed from the time the Vines are started into growth till they have finished their crops. The most important times to soak the borders with warm water are when the house is shut up for forcing, just before the Vines are in flower, and when the berries commence colouring. If the borders are well drained which they ought to be for Vines—more frequent applications of water will be necessary to maintain them in a favourable condition for the growth of the Vine roots, and, except in the dormant season, water at a high temperature will be found most conducive to the health of the Vine, the heaviness of its yield, and the perfecting of its crop.

J. RIDDELL.

PREPARING FOR PLANTING.

AFTER the small fruit is mostly over and Strawberry layers potted there comes a little lull in the work among hardy fruits, and if time can be spared to prepare stations for fruit trees to be planted during the autumn, it relieves the press of work later. Not only this, but as soon as the trees arrive they can at once be unpacked, the roots put in order, moistened, and planted without any delay. This early preparation of the stations is especially necessary where trees are to be planted on the grass in heavy, unkind soil. In a great many cases the gardener has to make the best of positions that are quite unsuitable for the trees, and, without questioning the economy or wisdom of owners in allotting such places to fruit growing, must do the best with whatever means are at command to at least give the trees a start in fair soil. During the whole of the year all waste soil from the potting-bench, edge cuttings, and other material are best thrown into a heap and turned occasionally, this making useful stuff to remedy the class of soil referred to. Here I always keep a heap or two going ready for whatever planting or mulching is going on, and it is extremely useful. The soil here is very heavy and close, and is taken out 18 inches deep by about 4 feet wide. First, the bottoms of the holes are well broken up with a pickaxe, the turf is placed on this, and a wheelbarrowful of the soil mentioned above is mixed with the rest of that taken from the holes. This addition allows of the soil being very firmly rammed—the work is, of course, done in fine weather—sufficient being left to slope up well in the middle of the hole, preventing undue gathering of water should the early autumn prove wet. To take out holes and fill them with loose soil without ramming or rounding off the surface is very wrong, as the holes get wet, and planting, instead of being forwarded, is in a wet season delayed. In the case of light, easily-worked soil the work is, of course, very much easier, and the best plan, if the holes are to be got ready previously, is to take the soil out, lay the turf back in the hole, and leave the rest of the soil ready by the side of the hole for planting when the trees arrive. Additions to this class of soil will consist of any loam that is to spare and a few barrowloads of clay that has been weathered by a good baking through the summer. The refuse from brick-kilns where brick-making is carried on on the estate is a very useful addition to all soils, while of course the oft-recommended burnt garden rubbish is of the greatest benefit, especially to Apples. I have seen in many places a fair thickness of spit manure placed in the bottom

of the station for fruit trees, but if I were dealing with the poorest soil imaginable, I should not use it. Far better let the trees be planted almost on the surface and keep up the fertility of the soil by frequently top-dressing with short manure.

Where the soil is naturally unfit for fruit culture, there is nothing gained by planting large trees, but rather the reverse. If maidens are planted—and these are cheaper of course than any other larger form of tree—the roots become used to the soil, as it were, but large trees with a lot of roots that have been growing in suitable quarters are never happy afterwards. Feeding from the surface, too, is much more easy in the case of these small trees, and any element that is missing in the soil, as lime, potash, or what not, can be easily and cheaply applied. August is a good month for preparing, where possible, borders for Peach, Nectarine or other fruit trees in the walled-in garden. Where pyramid and bush Apple and Pear trees are to be planted, the land may with advantage be got ready. Old kitchen gardens are often too rich in humus for fruit trees, and lime rubbish, burnt earth and a preparation of sound poor loam is the best addition here. The ground should be trenched, the bottom well broken, and the top spit flung up roughly in dry weather, mixing the material above-named with the top spit as far as possible. Plums, Cherries and stone fruits generally should not be planted in newly trenched ground if it can be avoided, and if the quarters can be cropped during the summer, the crop removed and the trees planted upon the firm soil, they will generally do better. The roots at first made are of the right sort for fruit production, but in loose soil Plums especially run away, and the makeshift remedy of root-pruning has to be commenced in about the second year after planting. All borders for the reception of bush fruits of kinds may also be got ready, and by these means a lot of time is saved, especially in a wet season. H. R.

Strawberry Royal Sovereign.—Mr. Hammond, one of our large Kentish fruit growers, gave Royal Sovereign as a market Strawberry the other day a remarkable testimonial. He said that it fruited before Sir J. Paxton and later, the latest produced fruits swelling up better than did those of any other market variety. That is high praise from such a quarter. It will be interesting to learn whether others have found a similar habit. Varieties suited for market command exceeding interest in Kent, where so many hundreds of acres are planted with Strawberries, and in that county hundreds of thousands of Royal Sovereign have been planted. Out in the open fields the tendency to produce long leaf-stalks is less evident than is the case in gardens. —A. D.

Nectarine Early Rivers.—This fine Nectarine is again in splendid condition in an unheated house. The first fruits were gathered the last week in July, but the finest and best are now (August 8) being gathered. The large fruits require longer to ripen after the colouring begins than some kinds, and it is not at its best until it parts from the tree very readily. For this reason I always place a net or some sweet hay under the trees, as, no matter how carefully large trees are gone over, there is always a risk of a few dropping, and if these have nothing to break the fall they are, of course, ruined. This variety is exceptionally vigorous, and, notwithstanding a crop that would be considered far too heavy for most varieties, the fruit is of excellent quality and flavour. It comes in at about the same time as Hale's Early Peach, and forms a good succession to Waterloo in the same house. Its capabilities as a foreign variety have been shown by the fine fruits exhibited earlier in the present season, while its splendid constitution renders it an

admirable outdoor kind, ripening before Lord Napier or any other first-class variety. The tendency to stone-splitting sometimes noticed in the fruit on young trees should disappear when they become well established.—H.

FRUIT FAILURES.

ALTHOUGH we are getting pretty well accustomed to the total or partial failure of our

this is aggravated by cutting easterly winds, as is usually the case during April and May, the blossom does not get frozen, but, what is equally as bad as far as setting a crop is concerned, the tiny fruits are really starved from want of sap to hold them on the tree, and drop to the ground by thousands. I feel confident that this was the cause of the collapse of our splendid show of blossom this year, for there was no

Rose Gardenia (*R. Wichuriana* × *Perle des Jardins*). From a photograph sent by Mr. J. MacPherson, Trenton, New Jersey, U.S.A. (See p. 166.)

fruit crops we do not seem at all unanimous as to the causes that lead to it. Late spring frosts have been blamed, and doubtless there is good reason for it in many cases, but I very much question if late spring frosts are half so destructive as a long protracted spell of cold, cheerless weather while the trees are in bloom, and if

frost of sufficient intensity to injure any kind of bloom. Early Potatoes growing in the same plots as my fruit trees were not cut in the slightest degree, and I notice this year the same thing has happened with my largest Pear trees, viz., the best fruits are right on the exposed tips of the topmost branches, where if

frost had been the cause of failure they would have caught far more of it than those in the centre or lower part of the tree. These to my idea received a more direct flow of sap, and consequently were able to hold on until more genial weather prevailed. I have several re-grafted Pears that were worked two years since with Pitmaston Duchess, and although this variety is one of the most complete failures of all on pyramids, bushes, espaliers, and wall trees, yet these recently re-grafted trees set nearly every bloom and have four and five large fruits in a bunch. I can only account for this by the fact that these grafts had the roots and stock of large gross-growing hardy Pears to feed them, and consequently were kept supplied with sap just when the others were starving. My fruit-tree grounds run full north and south, and if you pass down the east side you would say there would be no crop at all on the Pear trees; but if you return on the west side, you would find a fair average crop on several, which seems to me proof that it was cold winds more than actual frost that did the mischief. Of one thing I feel certain, and that is that as a rule we get far too much bloom, for the trees get exhausted with such a wealth of blossom and are unable to perfect any of it; consequently it all falls to the ground, while those trees that have only a mere sprinkling of bloom and hardly attract our attention during the flowering season manage to set these few, and in the autumn present a far more fruitful look than those that were like a nosegay all over. At all events I mean to thin the fruit-spurs a good deal more in future.

Gosport.

JAMES GROOM.

ROOT PRUNING OF FRUIT TREES.

Root pruning of fruit trees is what may be termed a necessary evil—necessary because either an unsuitable stock, a too severe shortening of the growths, or the destruction of surface roots will lead to the production of unfruitful wood. In some instances bush trees of strong growing varieties of Apples worked on the Crab stock are planted along the margins of walks to form a screen to the vegetable quarters, and at the same time to yield a supply of fruits. After a few years these trees attain the dimensions their allotted space will allow, and then severe annual pruning has to be resorted to to keep them within it. The more they are pruned the stronger the shoots become, as the balance between root and branch—the condition of a healthy fruitful tree—is gradually lost, and excessive crops of wood only are the reward. The cultivation of the ground, or rather the digging of it under the trees, results in the destruction of the surface and most valuable roots, compelling the plants to seek food in the under stratum. This stratum, or layer, is often of an unsuitable character, containing too much nitrogen in proportion to the soluble mineral matter, an excess of iron or compounds not at all favourable to the formation of fruitful growths. By a selection of trees on the Paradise stock, and merely pointing the soil under them to a depth of something like 2 inches during the winter months, the evil of strong succulent wood will, to a large extent, be avoided, and in favourable seasons good crops secured. Where these conditions have not obtained, and root pruning becomes a necessity in order to bring about a balance between the roots and branches, the operation is often delayed till late autumn or winter, or even till spring. When done at these times, the trees will get a check the following year and fruit the next. If, however,

the trees were root pruned at the end of August, the desired conditions would be obtained, the plants thoroughly established the same autumn, and a crop of fruit might be expected the year after. A year is thus saved. When I say "root-pruning" I do not mean digging round the trees at a certain radius from the stem and ruthlessly chopping off all roots that come in the way. Rather I would work round the plants with a fork, preserving all fibrous roots, carefully cutting the strong ones with a sharp knife, also sawing off all those growing vertically under the plant. Operators should be careful not to overdo the pruning of the roots. In cutting, cut from the under-side of the root in a slanting direction towards the top. This will encourage the formation of young rootlets on the top side of the root when it is cut, and secure feeders of the best kind within the surface soil. Although I have only mentioned Apples in this note, these remarks are equally applicable to other fruit trees. Always secure trees on dwarfing stocks, when they are obtainable, for confined spaces, and rather crop the ground with bush fruits around them than utilise it for crops necessitating deep cultivation. There will then be less occasion for performing root-pruning. J. RIDDELL.

BOOKS.

INSECTS, FOES AND FRIENDS.*

This little work is, as it is stated in the preface, a translation from the German. A glance at the plates before reading any of the letterpress revealed the fact that it was "made in Germany." It is difficult to understand why anyone should have taken the trouble to "translate and adapt," as the preface says, this little book, as it only contains 134 pages of letterpress, measuring $5\frac{1}{2}$ inches by $3\frac{1}{4}$ inches. It is impossible to deal properly with our "Insects, Foes and Friends" in so small a compass, and the impossible is not attempted, for the editor in his preface says: "It does not pretend to be anything like an exhaustive work on the subject, but a considerable number of the more interesting and typical pests of the farm and garden are figured and described." There are thirty-two chromo-lithographed plates: those of the larger insects are very fair, but those of many of the smaller ones are quite unrecognisable, the wireworm and its parent the striped click beetle for instance. In a book evidently intended for unscientific persons, where there is no glossary, such terms as pro-thorax, floeculent, permeate, pupa, larva, translucent, pulvilli, apterous, pubescence, &c., should not be used, as they convey no meaning to the ordinary gardener or farmer. Some of our most destructive pests are passed over with very scant notice—for instance, the grubs of the common daddy-longlegs are among the commonest and most destructive insects to many kinds of plants, but they are passed by with the statement that they "are very destructive, especially to the roots of corn and grass." No figure is given of them, and no remedies or preventive measures are mentioned. Wireworms are not much better treated. As a preventive it is said "that shallow drilling may be useful, as the young plants at this stage have such small roots that they are not likely to be injured by the drill." What operation is intended to be understood by the term drilling I do not understand. Again, the caterpillars of the winter moth are perhaps the most destructive pest to fruit trees in the spring. The only means suggested of combating this insect is that of "painting a ring of lime or tar round the trunk; sometimes this application is spread on straw or paper." There is no suggestion when this should be done, and I presume that the editor is unaware

* "Insects, Foes and Friends." By W. E. Kirby, M.D. Partridge and Co.

that the tar should never be painted on the bark, but always on paper, and that there are better substances than tar for the purpose, and that there are such remedies for killing the caterpillars in the spring as pyralin washes and Paris green. In fact, the remedies in most cases are quite out of date. So that the book is practically of little or no value to those who want to know how to protect their crops from their insect foes.

G. S. S.

SOCIETIES AND EXHIBITIONS.

NATIONAL CO-OPERATIVE FESTIVAL FLOWER SHOW.

CRYSTAL PALACE, AUGUST 19 AND 20.

No similar meeting probably brings together from so many different parts of the country persons interested in their gardens as does this annual gathering of co-operators. It may justly be said that the Agricultural and Horticultural Association in promoting this annual exhibition of garden produce are influenced by commercial considerations; but it can be placed to their credit that they have largely helped to create a multitude of amateur gardeners, who bring examples of their productions from many and widely separated districts. These amateur gardeners obtain their seeds from the London centre through the medium of provincial co-operative branches, and at a certain season of the year they bring their produce to London and exhibit it, allured in part by the offer of substantial prizes, but also, there can be no doubt, animated by a desire to take part in a great demonstration in the interests of co-partnership in trade, in the social observances which form a part of the gathering, and with a firm belief that the principle of co-operation is one of supreme interest in the working out of social and industrial ideals. But it is with the flower show rather than with the general co-operative movement that we have to do. That it increases in extent annually there is abundant evidence, the entries this year exceeding those of any previous show. There were 4321 entries, comprising over 5000 exhibits. The schedule of prizes included some 300 classes, and it is divided into three sections; nearly one half is confined to members and customers of the Agricultural and Horticultural Association or their gardeners and employes, and in the latter term are included some of the best gardeners of the day. Their exhibits consisted of vegetables, generally of fine quality, cut flowers, mainly annuals, but including some grown in greenhouses, plants in pots, with fruits and farm produce. The classes were generally well filled and the competition in many of them very keen. Side by side could be seen leading fruits grown under glass—Grapes, Melons, Peaches, Nectarines, &c.—and those from the open ground, early Apples and Pears, the homely and wholesome Gooseberry and Currant being largely represented. The owner of a spacious domain was in the same section with the village postman, and it was noticeable that the produce of the latter compared favourably with that from the gardens of the former. There were pretty floral decorations, also tables, epergnes, bouquets, &c., generally the handiwork of the women among the co-operators. As a rule they exhibited a considerable amount of taste in their construction.

On the second day the members of industrial co-operative societies and residents in the metropolitan district brought their produce to the extent of two-thirds of the exhibition. The spacious nave of the Crystal Palace was then well filled from end to end with lines of tables and also at the sides. The productions from the members of the industrial co-operative societies outnumbered those of the professional growers by four to one, and it must be admitted the general good quality was as high. In the matter of vegetables, Potatoes led the way in the number of entries, as in this section alone there were 239 dishes.

Beans, Broad and French, were largely represented, and so were Vegetable Marrows, Onions, Turnips, Peas, Beet, Shallots, Carrots, &c., following in the order of numbers. The most difficult task set the judges was the classes for Potatoes and Onions, as special varieties had to be identified, and some eliminated as contrary to schedule. In the classes for flowers, charming bouquets of annuals and biennials were staged. Annual *Chrysanthemums* were very good, so were *Salpiglossis*, Stocks, Carnations, Dahlias, including some excellent Cactus varieties: Sweet Peas, Mignonette, Indian Pinks, and *Phlox Drummondii* were all most attractive. The classes for bunches of annuals of one colour were full of interest. The leading yellow flowers were *Eschscholtzia*, *Coreopsis*, and Marigolds; red: *Malope grandiflora*, *Phlox Drummondii*, *Linum grandiflorum rubrum*, Sweet Peas, &c.; blue: Cornflower, Sweet Peas, *Whitlavia gloxinioides*, and Larkspur. The most effective bunches of annuals were those in which but one variety was placed. The mixing of varieties is often confusing rather than otherwise. Sweet Peas and the brilliant *Salpiglossis* were largely employed for this purpose.

There was evidence that the industrial co-operators can grow good fruit. They had fine cooking Apples, including Peasgood's Nonsuch, Lord Suffield, Warner's King, Emperor Alexander, and Hollandbury. Of dessert Apples there were Beauty of Bath, Gladstone, Juneating, and Quarrenden. The leading Pears were Jargonelle and Bon Chrétien, and there were excellent Morello Cherries.

There were prizes for photographs of flower and window gardens, of which there were 300 entries, and the Countess Grey offered a challenge cup and Earl Grey a shield, which added greatly to the interest of the proceedings. Mr. George Waugh as the director of the show carried out the arrangements in an excellent manner.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 23.

At this meeting the chief feature of the display was the large and varied collection of Gladioli staged by the Langport firm, and which included some excellent novelties, these being supplemented by several very fine banks of hardy flowers. A small collection of annuals was a noteworthy group, and included many subjects rarely so well represented. The *Salpiglossis* alone were of exceptional merit, and not only were the well-known blossoms seen in fine condition, but lovely self-coloured flowers in a variety of colours were much admired. A nice representative collection of the perennial *Phloxes* was a pleasing feature, and these embraced many well-known sorts, among them being many flowers of bright and striking colours. Of *Bouvardias* there was an excellent display for so early in the season. Most conspicuous was a splendid lot of *Bouvardia Humboldtii corymbiflora*, the collection numbering some twenty varieties. A fine example of the Japanese Wineberry occupied a prominent position at the meeting, and attracted much attention; so, too, did a very meritorious collection of Apples from Maidstone. Orchids were staged in very small numbers. Taken as a whole, the meeting was a good one for the season, only one side table being omitted from the ordinary display.

Orchid Committee.

An award of merit was adjudged to—

DISA CLIO (D. Veitchi × D. grandiflora).—To illustrate the variability of this secondary hybrid four plants were shown, the upper sepal in some being delicate rose with rose veinings, while in others the salmon-red of D. grandiflora was more pronounced with the markings of reddish purple, the lower sepals also being equally variable and the colours similar. The size of the flowers has been considerably increased. The habit of growth is also stronger. It is of free habit, and, possessing a good constitution, should prove a valuable

and useful hybrid, flowering at this season when all Orchid flowers are scarce. From Messrs. J. Veitch and Sons.

A botanical certificate was given to—

ACINETA COLOSSEA, in which the sepals are creamy white, the petals similar in colour, slightly spotted with pale brown at the base, the large lip also creamy white, becoming suffused and spotted with purple at the base and through the centre. A cut raceme of ten flowers came from Mr. F. W. Moore, Botanic Gardens, Glasnevin.

Messrs. H. Low and Co., Bush Hill Park, Enfield, sent a small but choice group consisting of a fine form of *Sobralia xantholeuca*, well-flowered plants of *Cattleya bicolor* and *C. Harrisoni*. Among the hybrids was the distinct form of *Laelio-Cattleya elegans enfieldensis*, one of the L.-C. e. *Turneri* section, but with very pale sepals and petals, which were in striking contrast to the crimson-purple lip. L.-C. *Aurora* (L. *pumila* × *Cattleya Loddigesii*), with three of its delicate rose and purple flowers on a spike, *Lælia Amanda*, with two fine flowers, the sepals and petals nearly white, mottled and veined with rose, the ground colour of the lip creamy white, suffused and veined with bright rose-purple, and a grand plant of *Phalaenopsis amabilis* were also shown. *Cypripediums* were well represented by fine forms of *C. Curtisii*, good varieties of *C. Charlesworthii*, and a fine plant and variety of *C. bellatulum album*. *C. Lawrenceanum Hye-anum* (Low's var.) has a very fine dorsal sepal, but the plant was too weak to develop its characteristics properly. Some fine forms of *Oncidium Lanceanum* were also included. Messrs. F. Sander and Co. sent a fine form of *Odontoglossum bictonense album* with three spikes of flower, a small plant of *Oncidium incurvum album*, *Cattleya velutina* with two spikes of flower, a grand form of *C. Gaskelliana*, and some distinct forms of *C. Leopoldi*. In *Bulbophyllum grandiflorum*, one of the most distinct and interesting of the large-flowered section, the broad upper sepal, upwards of 4 inches in length, has a pale greenish ground, suffused with brown and spotted with numerous large creamy white spots, the lower segments pale green, suffused and mottled with pale brown, the small lip pale green, suffused with dark brown. *Bulbophyllum barbigerrum* is a most attractive and interesting little Orchid. Messrs. J. Veitch and Sons, Ltd., sent *Masdevallia Circe* (*Veitchiana* × *Schroderae*), a pretty form, the yellow ground thickly covered with bright purple spots. In *Epidendrum radicante-Stamfordianum*, a hybrid raised from the species indicated in the name, the sepals and petals are rich yellow, suffused and spotted with orange-red, the lip more yellow than the other segments, spotted on the outer margin with orange-red. The habit of growth is very similar to that of *E. radicans*, the leaves if anything being more robust. *Cypripedium Rothschildianum villosum*, derived from the parentage indicated in the name, has the dorsal sepal greenish yellow, lined with rich reddish purple, the petals yellow suffused and lined with brown. The lip has a rose-purple tint in front shading to creamy white. Sir Harry Fairfax, Ravenswood, Melrose, sent a fine form of *Cattleya Hardyana* with two flowers and a cut spike of *Odontoglossum Harryanum* with eighteen flowers on the spike (cultural commendation). Sir T. Lawrence sent a finely-grown and well-flowered plant of *Platyclinis* (*Dendrochilum*) filiformis carrying over 100 spikes of its golden-yellow flowers, and *Saccolabium Hendersoni*, whose scarlet and white flowers are now rarely met with in Orchid collections. Mr. G. E. Moore, Bourton-on-the-Water, sent two distinct forms of *Cattleya Trianae*, flowering from imported plants. Mr. Walter Cobb, Dulcote, Tunbridge Wells, showed *Cattleya intermedio-flava*, differing from the variety exhibited at the Temple in its having pure white sepals and petals and a delicate rose-purple mottled lip. Mr. Moore sent a yellow ground form of *Cypripedium Godefroyae leucochilum*, and Mr. N. C. Cookson showed one of the home-raised *Cattleya Hardyana*, which was an improvement on previous exhibits from this

batch of seedlings. Mr. T. Hogg, Woodside, Paisley, exhibited a small-flowered variety of *Cypripedium Lawrebel*.

Floral Committee.

The following received awards of merit:—

GLADIOLUS LEMOINEI MME. DESBORDES VALMORE.—This is a pretty salmon-pink, paler at the edges, with bright crimson markings on lower petals and deeper coloured veinings. From Messrs. Barr and Son, Covent Garden, and Messrs. R. Wallace and Co., Colchester.

HUNNEMANNIA FUMARILEFOLIA.—This is a Californian annual about 2 feet to 3 feet high, succeeding well on warm soils, and very pretty. A coloured plate was given in THE GARDEN of June 11, 1887 (p. 536). The colour is rich citron-yellow, with orange-coloured stamens, and it has finely-cut silvery green foliage. From Messrs. J. Veitch and Sons, Ltd., Chelsea.

LATHYRUS GRANDIFLORUS ALBUS.—This has large spikes of bloom, with immense individual flowers of the purest white. From Mr. John Green, Dereham, Norfolk.

NYMPHEA ODORATA SULPHUREA GRANDIFLORA.—Handsome flowers of this fine variety were shown in conjunction with *N. Chromatella*. The petals are long and pointed and of a sulphur colour, with rich orange-yellow centre. From Mr. Leopold de Rothschild, Gunnersbury House, Acton (gardener, Mr. Hudson).

Messrs. Kelway and Son, Langport, Somerset, staged some fourteen dozen spikes of Gladioli, of splendid form and beautiful colour. Newer sorts largely predominated, and included *W. G. Grace*, a flower with a pink ground, flaked dark reddish crimson, with a cream throat; *P. H. Latham*, pale salmon-pink, edged rich salmon-pink, with lilac-purple markings on the lower petals. Ragged Robin was another clear salmon-pink, veined white, with a white throat, deepening to lilac at the base. This is a spike of even and good form. A pleasing contrast to the more showy colours was *Mrs. Garrett Anderson*, with large individual flowers of good form, white, veined bright purple, with purple base. A very rich deep chestnut-crimson was seen in *Sir George Newnes*, the colour deepening at the base. This was a very welcome display and imparted considerable brightness to the meeting (silver-gilt Banksian medal). The display from Messrs. R. Wallace and Co., Colchester, occupied one side of a table the whole length of the building, and contained several examples of their hardy Lilies. *Lilium Henryi* and *L. auratum platyphyllum* were massed in the centre, contrasted with several vases containing a nice lot of *Lilium Batemanie*. Of *L. tigrinum splendens*, with its fine flowers and large dark spots, there were some fine blooms, and these, together with *L. speciosum rubrum*, made an interesting exhibit. Gladioli were freely staged, and a nice lot of *Kniphofias* assisted to merit the silver-gilt Banksian medal which this collection gained. From Messrs. Barr and Son, Covent Garden, came a nice representative lot of hardy flowers, in which handsome bunches of the perennial *Phloxes* predominated. Among the *Phloxes* there were some highly coloured examples, notably in *Aurora*, a brilliant orange-scarlet, with bright purple eye; *Jocelyn*, fine cardinal, very brilliant; *Tempête*, deep carmine-rose; *Sir Frederick Leighton*, fine large head, with individual pips of immense size and of a beautiful carmine-rose. White flowers were well shown in *Panama*, with massive branching spikes, and in *Sesostris* was seen a good purple. *Burnoup* is a large and handsome flower of a bright brick-red and very effective. *Lilium Batemanie* and *L. tigrinum Fortunei* were each seen in good form (silver Flora medal). A very choice and select group of annuals in a cut state was staged by Messrs. J. Veitch and Sons, Ltd., Chelsea, and was convincing proof of the charming flowers there are among these. The *Salpiglossis* were very fine indeed, and appear to be comparatively little grown. These were represented chiefly in lovely self-coloured flowers, and in a great variety of

most refined colours. There were several veined flowers of a pleasing kind, but the selfs were distinctly good. For cutting the *Salpiglossis* should be freely used for all forms of decoration, where their value should be at once appreciated. In this collection there also were the double-fringed *Dianthus*, Larkspur Empress (rose) and *Lavatera* (Tree Mallow). The blue Swan River Daisy (*Brachycome iberidifolia*) was a beautiful piece of colour. *Phlox Drummondii grandiflora*, *Dianthus The Bride*, and the lovely *Hannemannia fumarifolia* completed a delightful list of annuals, which well merited the distinction they received. *Salpiglossis* were also finely shown by Messrs. H. Cannell and Sons, Swanley. Handsome bunches of these flowers in a charming variety of colour were most interesting, and in addition a fine lot of Sweet Scabious was much admired. A small group of well-grown Cockscombs from this firm was very fine. A silver Banksian medal was awarded. A grand bank of hardy flowers in large handsome bunches was pleasingly set up by Messrs. T. S. Ware and Son, Hale Farm Nurseries, Tottenham, but this lost much of its effect by being too crowded. Dahlias, too, were shown in large numbers, both pompon and Cactus types of the flower being freely displayed. Of the pompoms, several of those sorts which have long held favour, and such as Crimson King, Tommy Keith, Darkness, Mars, Sunshine, Achilles, among the Cactus forms, were set up in pretty sprays. Of the hardy flowers, *Lilium auratum vittatum*, *L. auratum*, *L. tigrinum splendens*, *Scabiosa caucasica*, *Delphiniums*, *Erigeron speciosus*, *Helianthus*, *Pentstemon barbatus Torreyi*, *Aconitum autumnale*, *Echinacea purpurea* and many other interesting hardy plants were well shown (silver Banksian medal). The collection of *Bouvardias* which came from Mr. H. B. May, Dysons Lane Nurseries, Upper Edmonton, occupied the whole length of the table, and comprised no less than twenty varieties. The most noticeable among them were *Bouvardia Humboldtii corymbiflora*, with very large pips on trusses of blossoms which were freely displayed, and these were of the purest white. A bright scarlet is *President Cleveland*, and developed in dainty bunches, and a free and chaste variety was also seen in *candidissima*. *Reine des Roses* is a beautiful salmon-rose, and with *Maiden's Blush* and *Purity* completed the list. A handsome double form of zonal *Pelargonium* was represented by *Anna Bateman*, a pleasing salmon-pink. This group was edged with *Ferns* and formed a welcome contrast to the more showy subjects in other exhibits (silver Flora medal). A large group of miscellaneous plants was pleasingly set up by Mr. Purnell Purnell, Woodlands, Streatham Hill, including tuberous *Begonias*, *Fuchsias*, *Liliums*, *Ferns* and other fine-foliaged plants. A silver Banksian medal was awarded to this group. From Sir Trevor Lawrence, Bart., came a collection of *Gladioli*, *Rudbeckia bicolor* and some seedling *Anthuriums*. A charming rose-pink *Verbena*, *Ellen Willmott*, was much admired (silver Flora medal). A splendid plant of *Rubus phoenicolasius* (Japanese Wineberry) about four years old had been lifted from the open. This is an excellent plant for trailing over large boulders in the rock garden and the fruit also makes a delicious preserve. This came from Messrs. J. Veitch and Sons, Ltd., Chelsea.

Fruit Committee.

Awards of merit were given to—

APPLE LANGLEY PIPPIN, a cross between Cox's Orange Pippin and Mr. Gladstone. It is not unlike Cox's Orange in appearance. The flesh is soft, very early, and of good quality. This will make a good early dessert variety, and the fruits are of good shape and colour. From Messrs. Veitch and Sons, Ltd., Chelsea.

TOMATO CURRANT.—This, only a little larger than a fine Red Currant, is of good flavour, very free cropping and a good decorative variety. From the Royal Horticultural Society.

Messrs. Bunyard and Co., Maidstone, staged a very fine collection of Apples, Pears, Peaches,

Plums and Nuts, in all some sixty dishes. The fruit was particularly bright, the best Apples being Golden Spire, White Transparent, Yorkshire Beauty, a beautifully coloured pale waxy fruit, Mr. Gladstone, Duchess of Oldenburg, Manks Collin, and Lady Sudeley. The Pears most noticeable were *Petite Marguerite*, Dr. Jules Gayot, Beacon, and *Beurre d'Amanlis*, of splendid colour. *Galaude*, Dr. Hogg, Stirling Castle, Dymond, and *Royal Charlotte* were the best Peaches, *The Czar*, *Early Prolific*, and *Comte d'Athene* being the best Plums (silver-gilt Knighting medal). Messrs. Rivers and Son, Sawbridgeworth, sent very fine *Dryden Nectarines* and *Early Silver Peach*, with *Oullin's Golden* and *McLaughlin's* and other *Gage Plums*. They also showed excellent fruits of their late *Frogmore Gage*, a very beautiful Plum, and *Peasgood's Nonsuch Apple*, very fine for so early in the season (silver Banksian medal). A neatly arranged exhibit came from the Dowager Lady Freake (gardener, Mr. Rickwood), Fulwell Park, Twickenham. Here were good *Morello Cherries*, *White and Red Currants*, *Black Hamburgh Grapes*, well coloured with good berries, nice fruits of *Beauty of Syon* and *Syon Perfection Melons*, good *Plums*, excellent *Peaches*, including *Early Louise*, *Alexandra Noblesse*, *Hale's Early* and *Goshawk*, *Lord Napier Nectarines*, *St. John's Figs*, *Pears* in variety, and early *Apples* (silver Banksian medal). Mr. Miller, Ruxley Lodge Gardens, Esher, received a cultural commendation for six dishes of *Figs* and *Peaches*. The same award was given to Mr. Hudson, Gunnersbury House Gardens, for *Strawberry Royal Sovereign*, very beautiful fruits for the season, being well coloured and of good size and quality. These were gathered from plants that had been forced and planted out in the early summer. The same exhibitor sent alpine *Strawberries* to illustrate the lecture, the varieties being *Belle de Meaux* and *Rouge Amelioré*. Messrs. Laxton, Bedford, sent good fruits of the little known *St. Joseph*, a perpetual fruiting variety, both fruit and plants in pots being staged. This is a good late fruiting variety, and will prolong the *Strawberry* season. The same firm sent *Laxton's Perpetual*, a variety that fruits from the new runners after the parent plants have fruited. This will be an acquisition. Messrs. Cannell, Swanley, sent fruiting plants in pots of *Louis Gauthier* and *St. Joseph Strawberry*. Messrs. Harrison, Leicester, sent fruiting sprays of the new *Strawberry Raspberry*. Mrs. Abbot (gardener, Mr. Kell), South Villa, Regent's Park, showed fine *Sea Eagle Peaches*, and a white-fleshed *Melon* came from Mr. Henderson, Buscot Park, Faringdon. A new *Tomato*, named *Beauty of Sark*, was staged, but it was very much like *Duke of York*.

NOTES OF THE WEEK.

Spiræa venusta in moist places has been a very effective this season, and perhaps may be cited as one of the most effective of the herbaceous kinds, both in the arrangement of the mass of blossoms and in colour. Where root moisture is plentiful the plant increases rapidly, and in the border when the season is not one of continuous drought and heat this species affords a good display of its pretty flowers.

Ononis rotundifolia.—This pretty plant has flowers of a rather unusual colour, and is invariably much admired when in bloom in the early summer. It is referred to just now because of the approach of ripening its seeds, and because the plant is well worth increasing by this means. The plant is not fast-growing, and the seeds are safe when sown in the open ground in shallow drills of fine soil. In this way the young plants take up but little room and attention.

Anomatheca eruenta.—This is a pretty bulbous plant of easy culture in pots and flowering during this and the coming month. If planted out it should only be in very warm positions, where a sheet of glass can be placed over it, or, better still, it may be lifted and kept in dry sand or earth till the end of February. In the late summer the crimson-red flowers are very showy, and the plants, if given liberal treatment after

a season of rest, will be found very interesting when in bloom.

Lapageria alba.—Mr. W. Milner sends us from his garden at Tutley Hall, Sheffield, two very beautiful sprays of this Chilean climber wreathed in bloom. They are the finest specimens of this we have ever seen. As a cool greenhouse climbing plant the forms of *Lapageria* have but few rivals, a peaty, free open soil being essential to their well-being. We should like to know something of the treatment by which Mr. Milner obtains such fine growths.

Nierembergia rivularis is a pretty low-growing plant with large, nearly pure white flowers of considerable size when compared with the habit of the plant. Planted in cool and comparatively moist spots, the plant spreads rather freely, and large patches in some garden soils soon result. In others, again, the plant does not seem so happy. Where strong clay soils obtain and the drainage is poor, the plant is scarcely hardy in winter. Difficulties of culture have been overcome by a free addition of leaf-soil, grit, and occasionally peat siftings.

Oenothera macrocarpa.—As a showy, free-flowering and vigorous-growing subject this fine Evening Primrose has much to recommend it, and the handsome pale yellow blossoms, being of large size, have a good effect. In the rock garden the plant trails freely, and for other positions also may be turned to good account. For instance, where large beds are planted with *Lilium*, *Gladiolus*, *Hyacinthus candicans*, and such like things, this Evening Primrose is a good subject for carpeting the ground, and being easily raised from cuttings as well as seeds, abundant stock for such free use may soon be had.

Carnation Leander. I have found this the most satisfactory of the yellow kinds. With me it makes a really vigorous growth, quite different in this respect from *Germania* and other yellow varieties I have tried, and the flowers are carried on good strong stems. I am of opinion that raisers of yellow Carnations should make much use of this variety, for no matter how good the quality of the flowers produced a *Carnation* that is of weakly constitution is of but little use. Among the yellows we sadly need kinds of a really vigorous nature.—J. C. B.

Bouvardia Humboldtii grandiflora.—Some time ago I referred to the above, and was then doubtful as to its proving quite distinct from *B. H. corymbiflora*, but now having grown the two varieties together I find the former a great advance on the latter, both foliage and flowers being of greater substance. It also appears to be very free flowering, plants in 5 inch pots with from eight to twelve shoots about a foot high showing bloom at every point. Some of the earliest have already opened some flowers which show a marked improvement on those of the older variety.—A.

Inula oculus-Christi.—The *Inula* described under this name on p. 169 is typical *Inula grandiflora*. It corresponds exactly with the type of *I. grandiflora* (Willd.) both in Kew Herbarium and in the Herbarium Boissier at Geneva. What usually passes in gardens for *I. grandiflora* is either *I. glandulosa* or *I. Hookeri*, or both mixed. *I. oculus-Christi* is not ornamental, making a scattered unbel of flowers resembling in size and appearance those of the native *I. dysenterica*. *I. grandiflora* may be seen now flowering in Kew Gardens under its right name.—C. WOLLEY-DON.

Pentstemon glaber.—Some nice plants of this have been more or less showy for some time past and flowering freely in the open border. Indeed, unless the soil is of good depth, the border is better suited to such as this than the rock garden, where the drainage is too rapid in times of great drought. There is a reddish tinge in the bright blue of the flowers of this plant that renders it effective, and when patches of more than a foot across are secured, there is freedom of flowering as well as profusion for a long time. A little later on cuttings may be secured of this, also such as *speciosus*, a nearly allied kind, and

the pretty bush-like heterophyllus, all of which are worth growing.

Erodium supracanum.—When this has formed good tufts of its deeply-cut leaves, the plants are almost daily covered with the whitish blossoms. These latter, however, are so heavily lined with reddish-pink veins as to give the blossoms an almost pink appearance. Small plants are not particularly showy, for the reason that only one flower is open at a time on each spike, but in a couple of years from seed, the plants, if given a sunny position in deep, gritty loam in the rock garden, will have formed good tufts and produced many spikes, continuing to flower for some three or four months in succession.

Tritonia rosea.—*Tritonia rosea*, which is often offered for sale under the name of *Montbretia rosea*, is at present in flower here. It may be of interest to other admirers of bulbous plants for me to say that I believe it to be quite hardy in the south-west of Scotland in warm borders. I was afraid to risk it outside until I had seen it in some other gardens in the district referred to. *Tritonia rosea* forms a pleasing change from the more massive spikes and flowers of the *Gladiolus* or the yellow and red *Montbretias*. Its habit is neat and graceful, and the rosy pink flowers are pleasing and useful for cutting.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Zephyranthes candida.—My first flower of the Peruvian Swamp Lily for the season opened to-day (August 22). Pretty as it is with its white Crocus-like flowers when fully expanded, it is, I think, even prettier when in bud just before it opens. Of a pure waxy white, but tipped with rose near the points of the segments, it looks exceedingly beautiful when surrounded by the stout grassy leaves. It is grown here in a warm spot at the base of a rockery, where it has almost a due south exposure and gets the sun the greater part of the day. One can hardly have too much of this beautiful bulbous plant where it succeeds.—S. ARNOTT.

Rosa Wichuriana.—A plant of this Rose put out in early summer is now in flower, and when growing and in bloom realises one's expectations formed from reading of it and seeing it elsewhere. Its shining green foliage and its single white flowers are charming in the rock garden, for which it is so well suited. Like all the single Roses, the flowers are too short-lived for us to enjoy them long, but they are enjoyable while they last, and are soon succeeded by a few others. *Rosa Wichuriana* should have a fair amount of space allotted to it, and should form a good carpeting plant for spring bulbs.—S. ARNOTT, *Rosdene, Carsethorn, by Dumfries, N.B.*

Carnations from Kelso.—By accompanying post we send a few named blooms of our Carnations. All have been grown outdoors from layers planted last autumn.—LAING AND MATHER.

* * We are very pleased to find that some present-day raisers are devoting their attention to the beautiful self colours, and we hope that no new variety will be sent out until it has been well tried for two or three years in order to prove its value for the outdoor garden. Among the varieties sent are Mrs. David Dunlop, white; Lady Waldie Griffith, rich purple; Mephisto, dark crimson; Valkyrie, pink; Viscountess Melville, pale scarlet; and The Pasha, apricot-tinted.—Ed.

Meadow Saffrons.—On August 20 I observed the first of my Meadow Saffrons in full bloom. Some of the species or varieties are rather mixed so far as regards their nomenclature, but the two in flower were received as *C. Bertoloni* and *C. Bivoniae*. The former is of fair size, but rather paler in colour than the latter, which is pale purple. It is unfortunate that we have not more variety in colour among these Meadow Saffrons, but, taking them all in all, they are of much value, especially in gardens fully occupied with herbaceous plants, which as autumn advances are apt to be a little wanting in colour. In the rock garden the Meadow

Saffrons and autumn Crocuses are invaluable.—S. ARNOTT.

Leucojum autumnale.—This charming little autumn Snowflake has been in flower for a week or two, and one cannot resist the desire to draw attention once more to so pretty a bulbous plant. A little clump is delightful with its glossy white drooping flowers and chocolate stems. In two or three other places solitary flowers from seedlings have opened among other dwarf plants. Were it more plentiful, one could imagine the beauty of a sheet of some deep green mossy Saxifrage spangled with the little flowers of the autumn Snowflake. Here it does very well, and seedlings either from seeds saved and sown or self-sown are becoming plentiful.—S. ARNOTT, *Carsethorn, by Dumfries.*

Silene virginica (Fire Pink).—While this striking plant cannot be regarded as generally suited to the climate of Britain, yet it is one of the most brilliant subjects when in flower, and worth some care to get it established in the garden. Its flowers are of a vermilion-scarlet, very brilliant in colour—indeed, among the richest colours to be found among perennials. As a rule the small bits imported do but little good, and where an attempt is being made with the plant it would be safer, perhaps, to secure fresh seeds direct from its North American home, and sow at once in very sandy loam and peat in about equal parts. Slugs, however, are very fond of this genus, and some care will be needed to keep such away from this the most brilliant of its race.

Lithospermum prostratum.—Among the ever-popular blue-flowering plants, this pretty trailer is always admired when seen in good condition. With the great heat and drought of this year, however, it is only in few places the plant flourishes, and of these preference is given to a rather shady spot in good soil. Old plants that have put on a rusty look in the past often lose a lot of foliage near the centre. In other instances if a slight pinching or pruning be adopted and a good rich mulch given, both in early spring, there is hope of more compact tufts in what is certainly one of the most delightful of blue-flowered plants. It is now a good time to put in cuttings of this plant, the young bits stripped off with a heel attached being the best, and a cold frame or close hand-light, where a sandy soil has been prepared, the best position. Such cuttings as these root freely and are safe for the winter in such a position, with the lights removed in mild weather.

Sempervivum arachnoideum.—Despite the fact of this being one of the prettiest of the Houseleeks, it is only rarely one sees it spreading out into patches of sufficient size to command attention. With a little extra care it is a plant that may be made attractive, but when left to itself it frequently becomes crowded and ineffective. It is surprising what may be done with the tiny webbed rosettes that cluster round the larger ones by picking the former off and pricking them out into separate colonies by themselves. Growers of these webbed forms will not need reminding how much purer in tone as well as abundant is the web itself when the plant is in free growth, and since this is the characteristic feature of these forms, it is but justice to the species that the best side should be apparent. Some plants of *S. a. Lageri* so treated make a fine display. All that is needed is a patch of ground, say 2 feet across, rather sloping preferred, the loam freely mixed with old mortar, and the surface made quite firm. When this is done, dibble the rosettes out thickly over the surface and water thoroughly. During the season of growth the web-like down on the surface will be very pure and effective, due to the freedom of growth and greater sustenance enjoyed by the individual rosettes of these interesting forms, all of which are worthy of like treatment.

The weather in West Herts.—Another hot week, the highest temperature in shade reaching 80° on four days, while the nights were again very

warm. During the night preceding the 22nd the thermometer in the screen never fell lower than 60°, and on the following day rose to 84°, thus giving a mean temperature of 72°, which is higher than any similar reading recorded here since August 18, 1893. At 2 feet deep the ground is at the present time about 6°, and at 1 foot deep as much as 8°, warmer than the averages for these depths. Rain fell on but one day of the week, and then the amount deposited proved very small. The ground is consequently again becoming very dry, no measurable quantity of rain-water having passed through either of the percolation gauges for two days. The winds have been light and the air as a rule very dry. On the 18th the difference between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounted to as much as 17° at 3 p.m. The record of bright sunshine proved good, averaging nearly 7½ hours a day.—E. M., *Berkhamsted.*

PUBLIC GARDENS.

Royal Botanic Society.—At the annual meeting of the Royal Botanic Society, at which I took the chair, there was one aspect of the society I could not dwell on as I should have wished, and yet it is one of some importance. When the gardens of the society were first formed, not only were they intended to promote horticulture and the study of botany, but also to protect a spot in the centre of London where some of the quiet features of Nature might remain untouched, plants common in the country, but rare in London, might still find a home, and birds nest there undisturbed. To many, too, the sense of quiet and repose which the gardens gave was delightful—a feeling of rest which only the country can give. It was for these reasons that the Fellows reserved to themselves the right not to admit the public indiscriminately; that, like the squares, a character of privacy was maintained, though it was never difficult for quiet people to obtain admission, or any serious student of Nature. This spirit of exclusiveness is not now maintained, and the gardens are as much open to the general public as is possible, if they do not altogether lose the original intention with which they were formed, and the natural beauty, which they still possess, altogether disappear. To turn them into an inferior Ranelagh, or a bad imitation of the *Palmen Garten* in Frankfurt, would probably end in a financial failure, and take away one of the few places where the tired man of business, the invalid, and the old may find a few moments of repose, a few minutes of quiet, away from the noise of the crowded street, the cyclist, and the omnibus. They who like crowds have every opportunity of enjoying themselves in London, but those who would fain be a moment at rest hardly know where to go. Every day before the ruthless builder tranquil spots and relics of the past disappear. The few which it is possible to preserve become every day of greater value.—C. BRINSLEY MARLEY, in the *Times*.

Crocus vallicola.—In case of my bad example leading anyone else astray, permit me to say that *vallicola* is the correct termination of the specific name of this Crocus, and not *vallicolus*, as written in the note on p. 140.—S. ARNOTT.

Veronica Dieffenbachii.—I send blooming branches of *Veronica Dieffenbachii*, as yet uncommon. The thick leathery leaves and large handsome spikes of blue flowers, at length bleaching to white, render it one of the most ornamental as well as best marked species. The little cushions of *V. canescens*, less than half an inch in height, are now thickly studded with delicate miniature flowers. All the "whipcord" section, with the exception of *V. Hectori*, have bloomed this season.—ROBERT OKELL, *Sutton, Douglas, Isle of Man*.

Names of plants.—*D. M.*—1, *Gentiana septemfida*; 2, *Rumex crispus*; 3, send fresh specimen.—*Eduard Sutton*.—*Tecoma radicans*.—*C. E.*—1, *Viburnum macrocephalum*; 2, *Adiantum concinnum latum*; 3, *Adiantum formosum*; 4, *Davallia sp.*; 5, *Pteris scaberula*.

THE GARDEN.

No. 1398.—VOL. LIV.]

[SEPTEMBER 3, 1898.

ORCHIDS.

SACCOLABIUM CELESTE.

The pretty blue of this species is brighter and better than that of many so-called blue Orchids, at least in the better forms. It occurs on the tips of the sepals and petals and a great part of the lip, the rest of the flower being white. It is the contrast between this and the blue that makes the species so attractive. Like many others of this class of Orchid, *S. celeste* is much more satisfactory in some collections than in others, and it is difficult to say why. The plant is of a rather stiff habit of growth, and likes a small receptacle and rather poor root-hold better than a large body of material. For this reason I have usually treated it something on the lines laid down recently for *Vanda cœrulea* as to compost and baskets, but given it a higher temperature. The roots like rather to lay hold of something in the way of burnt clay or wood than to embed themselves in cubic inches of compressed Sphagnum Moss. It is more natural, and the plants under the circumstances keep longer in health. The size of the baskets depends, of course, on that of the plants, but I like one plant in a small receptacle, provided it is healthy and well rooted, better than a large made-up specimen in a larger basket. It runs dry quicker and the air plays with greater freedom about the roots and the base of the stem, an important point with these truly epiphytal species. As regards moisture, *S. celeste* can do with as much as most when healthy and growing freely; without it, in fact, it is useless looking for strong, vigorous growth, but the water must get away quickly. The plants must be on the dry side before a fresh supply is given, and then enough must be allowed to thoroughly soak every inch of the compost and every root in the basket. This point is, I firmly believe, where many amateur Orchid growers go wrong. An Orchid is not like a Heath; the roots may be quite dry for hours—are dry doubtless for days in their native

habitat—but the beginner in their culture if he sees a plant at all approaching dryness at the root proceeds to give it about a couple of tablespoonfuls of water. Better by far leave the plant until it is really dry even in the midst of the growing season, and then give a thorough soaking. A week's drying will not harm a healthy growing Orchid much, but to be always in a kind of medium state, neither dry nor wet, is bad for every kind of epiphytal species.

This beautiful *Saccolabium* likes more sun than the majority of distichous-leaved Orchids, and plants that get plenty of sunlight are always more free-flowering, and, I think, live longer under cultivation than others grown in a very dense shade during the summer months. The leaves are hard and stiff; they seldom drop at the axils after a long cold winter, and, owing to the amount of root moisture they are able to take under such conditions, they produce flowers of fine substance that last well in good condition and do not harm the plants. It is annoying, too, to grow a plant well and apparently keep it in the best of health for a time only to find after a while that spot has set in with all its virulence and destroyed in a few weeks what has taken months to build up. This has always been my argument against heavy shading. Grow the plants as strongly as possible by all means, and put on as many leaves as you can in a season, but let the growth be consolidated as it is made, or at next potting time the plant will be as small as ever owing to the number of leaves lost in a cold winter.

H. R.

Cattleya Loddigesi.—This is a lovely species and a rather variable one. It is one of the best kinds flowering now, and has been used rather freely by the hybridist. A hybrid between it and *C. Leopoldi* was very pretty, the flowers partaking largely of the *Loddigesi* shape, with the characteristic spots as seen upon the popular variety of *C. guttata*. The species is not difficult to grow, though not so vigorous as some, and it does well with other Brazilian species in the

intermediate house. It should be very sparingly watered during the winter months.

Cypripedium Charlesworthii.—This pretty and popular *Cypripedium* is still in good condition and to be seen in almost every collection visited. The one thing against it is that often the upper sepal loses the fine colour it has when first open, and what was a very bright and effective colour fades to a washed-out tint that is not very attractive. At Livermere recently I noted a plant that had been in flower a fortnight or over, and the colour was as good as when it first opened. If all the plants in cultivation did this the species would be even more popular than it is.—H.

Cypripedium Pearcei.—The long rhizomes of this species soon carry the growth out of the influence of the compost, and by growing over the sides of the pan or basket gets weak unless disturbed, which is against its flowering freely. I lately saw it planted on a moist rockery, and this seems to me to be one of the very best ways of treating it. The plants are evidently quite at home, for the roots have something tangible to lay hold of and are naturally much stronger than others growing in the air. It is one of the small points worth taking note of, especially by anyone not particularly successful with this pretty and out-of-the-common species.

Lælia monophylla.—This singular species I have noted in flower very much earlier than usual. It is quite distinct from any other *Lælia*, the flowers, occurring singly on the scapes, being bright red and individually about 1½ inches across. The plants were growing in an ordinary plant stove and appeared fairly happy. The bright flowers are certainly very attractive, and it should be more grown. *L. monophylla* dislikes much compost and usually thrives best if attached to blocks, and these placed in baskets with plenty of drainage and not much peat. It is a native of Jamaica, where it is found at a considerable elevation, and though long known has only been in cultivation since 1881.—H. R.

Zygopetalum Gautieri.—There is considerable variation both in the size and colouring of this fine Orchid, which is becoming much more popular than was formerly the case. It is a beautiful plant and one that is worthy of all care.

I have seen it doing well on many occasions in an intermediate temperature, but certainly the best growths and finest flowers I have seen are on plants grown in quite a cool house. The foliage and bulbs are so healthy and green as to leave no room for doubt that their position suits them, and they are, moreover, extremely well flowered. This species seems intermediate between the creeping section, such as *Z. rostratum* and *Z. maxillare*, and the stouter *Z. Mackayi*, and though it is hardly safe to give so much or so heavy a compost as for the latter, yet the stout fleshy roots require plenty of sustenance. Pieces of Tree Fern placed in pots and filled around with a free open compost form capital holding for the roots, and they have the choice of both stem and compost to run into. The growth is very free if kept clean, but scale is very fond of the tender bulbs and leaves, soon ruining their appearance if not checked. *Z. Gautieri* is a native of Rio, introduced about 1867.—H.

ODONTOGLOSSUM PARDINUM.

JUDGING by the appearance of the pseudo-bulbs, this pretty *Odontoglossum* should be more easily grown than the majority of species, for these are large and the roots look strong and vigorous. But this is not always the case by any means, and in many places it is far from well grown, though other and weaker growing kinds flourish. The pseudo-bulbs are pale green, the spikes of flower very large and occurring from the base. The ground colour of the flowers is a pale yellow, and this is covered with reddish spots on the petals and lip. To grow *O. pardinum* strongly larger pots than those used for most kinds are necessary, but a large amount of compost is not required. The thinner in fact this is kept the better, for the roots, though large, are soft and easily damaged by too much water. Very rough material is also required, the charcoal and crocks being broken into large lumps, the roots taking hold of these and thriving better than in a closer and more moisture-holding medium. With such species as this the need for care and judgment in watering is great, especially in winter and after the plants are repotted. Any slackening of moisture at the roots at a time when growth is active will be followed in all probability by shrivelling, and this must be carefully guarded against. But, on the other hand, the soft, fleshy roots once started to decay are not easily stopped, a black, burnt appearance being soon followed by the entire root dying. Of course this is more likely to happen with plants that have not a thorough hold on their compost, and is of frequent occurrence with plants in the second season. Some fine specimens I once grew upon trellised rafts did extremely well until the time for shifting came round—that is to say, when the rods decayed. Once disturbed, the plants never attained the same vigour they formerly had, the bulbs getting smaller annually because the roots failed to take a hold of their new home.

Another point that is very much against long-continued success with *O. pardinum* is the want of light during our long, sunless winters. For days the sun never shows through, and in addition the glass is not always kept as clean as it should be, the consequence being that these Orchid- from purely alpine latitudes do not have the chance to become robust. Air and light in winter are very necessary for them, and in the absence of these they become puny and weak, the foliage flaccid instead of stiff, while the unsatisfactory condition of the growth leads to weak flower-spikes. Flowering again seems almost too much for it in this weakened condition, and it is very remarkable that on newly-imported plants flower-spikes as thick as a man's finger have been produced without detriment, while a very much smaller spike will cause shrivelling under cultivation. The soft brownish scale that attacks coolhouse Orchids generally seems particularly at home on the soft bulbs and leaves of *O. pardinum*, and this in itself is a check to the plants.

Briefly, then, all that can be done is to always maintain a sweet, moist atmosphere in the house where it is growing, the temperature being as advised for New Grenadan species generally; to make as sure as possible of the roots getting a good hold of their adopted home—this at the same time being of a lasting character—and to keep foliage, bulbs, and roots clean as the term may be applied to each. This, with care in the ordinary cultural operations, will ensure a fair amount of success, but the species is not one of the best to grow, as shown by the long time it took to flower in this country after being discovered at Quito early in the century. Time after time it was collected, but does not seem to have arrived in this country alive, and the first account of its flowering is about thirty years ago.

Masdevallia Davisii.—This beautiful plant is now in good condition in a neighbouring collection, the pretty bright yellow of the flowers being very distinct. In shape they are a little broader in the lower segments, according to the size of the flower, than those of *M. Veitchii*, and the upper sepal is broad at the base and pointed. It does well in a cool, moist house all the year round, and should have a medium thickness only of compost, this consisting of equal parts of peat and moss over good drainage. Water freely all the year round and repot in early autumn directly the flowers are past.

Promenæa stapelioides.—The small and quaintly-coloured flowers of this Orchid do not find much favour with growers now-a-days, but all the same it is a pretty species worthy of extended culture. It grows freely enough if kept clean and in good condition at the roots, but if insects are allowed to run riot—especially thrips—and the roots get into close, heavy material, the plants soon go back. The foliage is easily injured by sunlight, being of very thin texture, so shading must always have close attention. Water freely all the year round, but especially when growth is active, and lightly damp the foliage in hot weather.

Cycnoches maculatum.—This singular species is not at all common, and one seldom comes across it. It is a stout grower and flowers freely, the racemes containing a large number of the quaintly-shaped blossoms. These are pale yellowish green on the sepals and petals, this colour being thickly overlaid with reddish purple spots. The lip is white. Like all the *Cycnoches*, it likes plenty of warmth while making its growth and a very decided resting season. It does with a good substantial compost and abundance of moisture, taking care not to damage the young growths by too much early in the season. It comes from Mexico, and first flowered in this country in 1839.

Aerides quinquevulnerum.—This pretty species is nicely in flower this week. It is very distinct and rather showy. The racemes are long, the individual flowers about an inch across, white, prettily spotted and blotched with amethyst-purple. It deserves better treatment, as it is very easily grown in a warm, moist house. Small pieces do well in pans or baskets hung up in the East India house in such a position that, while shaded from the midday sun, they get the full advantage of its rays in the afternoon after closing time. Grow it in Sphagnum Moss and charcoal only and repot in early spring. It is a native of the Philippines, and was introduced by Messrs. Loddiges in 1837.

Oncidium tigrinum.—One may easily tell when a plant of this superb *Oncidium* is in flower by the Violet-like fragrance, which is second to that of no other Orchid. The flowers, too, are very beautiful now at this dull season, and consequently more than ever welcome. *O. tigrinum* is purely a cool-house species, and as such must be grown. In a hot or stuffy house the pseudo-bulbs may be large the first season or so, but to obtain the hard, solid bulbs that one likes to see in this class, a cool structure amply ventilated is essential. In it the growths take on a deep green colour, they look robust, and have a rustling feel to the

hand when lightly passed over them. As regards the roots, these like rather closer compost than some species, but it must not be too thick, for they cannot push through a great quantity of it. Three parts of peat fibre to one of Sphagnum Moss and enough finely-broken crocks to keep it open suit it well, the best receptacle being pots of sufficient width to allow a fair margin all round the plant. It does not need to be much elevated above the rim, but newly-imported or badly-rooted plants must be kept up a little. Water must be judiciously applied to the roots all the year round, and light syringings are helpful in hot weather.

Dendrobium bigibbum.—Most of the New Guinea *Dendrobies* are doing well at St. Albans, and this is no exception. Among a large batch suspended from the roof of one of the larger houses there are some forty or fifty plants in flower, the bright magenta-purple of the blossoms making a bright and telling bit of colour. The varieties are all good, and as *D. bigibbum* is one of the very best for cutting, it is doubly useful at this time of year. The plants are producing fine healthy growths and vigorous spikes. They are grown in small pots and pans, as these suit this section much better than large roomy receptacles. The best peat only with a little Sphagnum Moss suits the species well, and the annual routine of culture is much the same as that recently described under *D. Phalenopsis*. This species in fact is growing by the side of it at Messrs. Sander's, and is equally at home. Good forms of the old *D. Phalenopsis* were noted besides the more popular variety *Schroederianum* with a few others. *D. bigibbum* is not, I believe, found exactly in New Guinea, but close by on the islands in the Torres Straits and the mainland of Australia. It was in cultivation a great many years ago very early in the present century, but probably was afterwards lost to cultivation for some years.—H.

RENANTHERA LOWI.

I saw two noble plants of this majestic Orchid lately in flower. The surroundings are such as to give a very natural appearance to the plants, the latter being backed up with Ferns and other fine-foliaged plants, a tank providing the atmospheric moisture which all this class of Orchids delights in, and with which this individual species is always associated in its native habitat. The plants are remarkable for their good health, and one is carrying four, the other three, of the immense spikes of flower. On each of these there are perhaps forty or fifty of the brightly-coloured flowers, but it must be noted that the blossoms of this species are dimorphous, the lower two or three blooms being quite distinct in character from the others on the same spike. This characteristic is particularly well shown in the plants referred to, and all the upper flowers are very bright yellow with reddish brown spots, the lower ones smaller and not nearly so bright in colour. The temperature where these plants are grown is not particularly high; the house may, in fact, be described as a warm intermediate one. Many of the roots do not enter the compost; in fact the majority are outside the pots altogether, looking as though they revelled in the congenial heat and moisture provided. The growth is evidently very free, and wherever the plant is grown it will require plenty of room. In a large stove, conservatory or similar structure this would have a splendid effect if trained up a tall dressed pole or Tree Fern stem; anything, in fact, that the roots could lay hold of as they are made, for without a doubt air roots are useful, as they act as auxiliaries to those in the compost. This fact is obvious to anyone who observes this kind of thing with the plants above referred to. The growths that are producing the flower-spikes are not the original tops of the plants, but side breaks that have appeared from the base since the plant has been imported. Naturally, these are more in touch with the compost, and the roots enter it at

once, giving additional strength to the plant, as evinced by this portion flowering while the tops are bare of spikes. They have evidently been some time in the pots, and it is a fact that all these large-growing species, such as *Renanthera eoccinea*, *Vanda Batemani*, *V. gigantea*, and others of this class, are far better if they can be left alone. Supposing a few of the older roots do perish in the old material, there will be plenty more produced, and by top-dressing with Sphagnum Moss and charcoal these will have fresh material to run into. *Renanthera Lowi* is one of the most remarkable of Bornean Orchids, and was found by Sir Hugh Low "hanging horizontally from the stems of large trees" in very moist positions overhanging the rivers. It has often been sent to this country, but is seldom seen in flower, owing, perhaps, in part to the difficulty in establishing it and also to the fact that only those growers having large houses can give it the room it requires. H. R.

CATTLEYA GASKELLIANA.

AFTER the flowering of *C. Mossie*, until the earlier plants of *C. labiata autumnalis* come in, there is no other species so useful as this, for though *C. gigas*, *C. aurea*, *C. Luddemanniana*, and others give a few flowers in the same season, none of these can be depended on, I think, so well as *C. Gaskelliana*. Not that this even is always constant, and time after time I have had plants grow out of season, but with care in management this will not occur to the same extent as it does with the kinds above named. As a rule the flowers are not quite so large as in the other labiata forms, but many are very good and some of great beauty exist. The ordinary *Cattleya* house temperature suits it well, and if there is any difference the coolest end of the house may be chosen, giving it a light position not far from the roof glass. Growth should commence in spring from the base of the leading shoots, and if the plants were well watered in autumn right up to the time they were well filled out they will not need much moisture until the bud commences to elongate, as the stored-up nutriment in the pseudo-bulb keeps it going so far. Never allow the plants to shrivel, though even a slight shrivelling is not so bad as undue moisture. I saw a fine batch of this species three years since that were dried very severely during the winter, and as soon as the shoots appeared at the base, the bulbs almost immediately shrank up to about half the normal thickness. I thought the plants would fare far worse than they did, for, seeing them again in the autumn, most of the old bulbs had again filled out, notwithstanding the new growths had flowered well. But the experiment was not repeated, and while far from advising heavy waterings in winter, especially late winter, too little water is almost equally bad. When the growth is small, light overhead moistenings may be given in the form of spray from the syringe, but a little later and before the leaf shows this must be discontinued. The flower-spikes appear at the top of the newly-formed growths and are usually about three or four-flowered. The colours are as varied as in others of the labiata group. There are also forms with very deeply coloured segments and others pure white. They last about a fortnight in good condition if not spotted with damp or bruised. After flowering, keep the plants well up in the house where they get plenty of air and endeavour to keep them quite dormant until after the turn of the year. *C. Gaskelliana* is a native of Venezuela, whence Messrs. Sander and Co. imported it in 1883. H.

NOTES AND QUESTIONS.—ORCHIDS.

Anguloa uniflora.—It is getting very late for this pretty species to be in flower, but I have noted it twice during the week. The growth in neither case had started rooting, and this bears out what I have frequently advanced, that it is in the majority of cases better to leave the plants until after flowering before giving new material. The flowers are nearly

pure white externally, with usually a few rosy pink spots inside.

Oncidium incurvum album.—This is a rare and pretty variety of a well-known species. The flowers are pure white with the exception of a yellow crest on the lip, the spike being much branched. The habit of the variety is the same as that of the type, and the culture is easy provided it is not kept too hot and moistened according to the state of growth.

Cœlogyne Massangeana.—This is one of the freest flowering of Orchids, and if a fair number of plants is grown keeps up a display more or less over the greater part of the year. Large plants I have noted this week have the flower-spikes just getting past, and another lot about 3 inches high. The spikes are about 20 inches long, and are covered nearly all their length with the somewhat dull-coloured but interesting flowers.

Stanhopea oculata.—This I have noticed in flower in several collections lately. The plant is a good grower and thrives well under the treatment advised for others in the genus. A fine variety I lately saw had two fine spikes, one of them carrying seven very large and highly coloured flowers, making a fine display and emitting a delicious perfume in the house. It is a native of Mexico, and was introduced by Messrs. Loddiges in 1829.

Cymbidium elegans.—A fine spike of this *Cymbidium* I noted lately. Though not a showy Orchid it is quite out of the common—more like *C. Mastersi* than any other—and very interesting. The blossoms are whitish or light yellow, drooping upon an erect spike, and they have the habit of remaining half closed, as it were. This species does well in a compost of equal parts of leaf-moss, peat and Sphagnum Moss. It is a native of Nepal, where it was discovered by Dr. Wallich about 1820.

Cattleya velutina.—This is not as a rule much cared for by Orchid growers, but in its best forms it is very pretty. The sepals and petals are a kind of old gold tint and very prettily undulated. The lip is whitish, with lines of purple radiating from the orange-yellow centre. Some forms have the lip entirely rose-purple, except a paler margin in front. Under cultivation this plant does well if treated like the varieties of *C. guttata* or *C. Loddigesii*, and flowers on the apex of the newly-formed growths. It is sometimes described as a natural hybrid, but this, I think, is extremely doubtful.—H.

BOOKS.

ROSES AT CANNES.*

THIS is a catalogue of Roses grown in Lord Brougham's garden at Cannes, and it is not made upon any fixed plan, as the descriptions vary very much. It is illustrated with the coarse process cuts now, unhappily, so common in books, and which fail almost completely to show the extreme beauty of the subjects chosen, such as that of a fine Banksian Rose growing over an Olive tree. There must be a great deal that is interesting in the culture of Roses in that part of France, which would certainly have been profitable to have gone into more fully, especially the question how the finer Tea Roses do on their own roots there. On this subject there is a sentence which in point of clearness leaves much to desire: "*Roses do well here on their own roots, whether as standards, bushes, or trees, if they are worked—that is, budded or grafted—on another stock.*" The amusing nonsense of this reminds one of some of the sentences of the people who explain that the Pansy is not a *Viola*. Although the list of Roses is pretty full, some of the great Roses are not included in it, such as *Anna Olivier* and *Bonquet d'Or*; but of this we cannot well complain, as Lord Brougham cannot grow every Rose, and must have his favourites. We append

* "Roses at Cannes." By Lord Brougham and Vaux. John E. Bumpus, Ltd. 1898.

a few of the descriptions of Roses that are less generally known here perhaps than some others, no doubt owing to difficulties of climate in some cases.

"CHROMATELLA.—Of all Roses in cultivation this is the most beautiful. Intense golden-yellow flowers, perfect in shape and substance, large, on big, firm stalks. This Rose has become capricious, and is difficult now either to grow or flower well; time was when it flourished exceedingly, and so abundantly that its flowers formed the usual decoration for churches, &c., at Christmas or Easter. Now, with every attention, it seems to languish and put forth but feeble flowers, but there are cases when left to itself it prospers as it did twenty-five or thirty years ago. One plant I remember in particular, placed apparently in a very unfavourable situation, looking north, and being on the edge of the grande route de Frejus, is for ten months out of twelve covered deep with dust; it has grown into and taken possession of an Olive tree, putting forth its splendid golden flowers here, there and everywhere, a sight that must afford true delight to all who love the Rose. Plants of this variety were taken to Kent about fifteen years ago, in the vain hope that they might prosper and flower. Some think that this and *Cloth of Gold* are one and the same, but I am inclined to believe they are distinct varieties.

"COMTESSE DE LEUSSE.—Tender rose colour, with centre shaded almost to gold, ruby-coloured buds, large flowers, not very full and imbricated. Plant vigorous, growing to a large size, very free-flowering, altogether a splendid variety; shows to great advantage in a semi-shaded situation. I do not think this fine Rose is much known in England, where, judging from its manners here, it should succeed.

"DUC DE MAGENTA.—Rose coloured, shaded to salmon. When grown in a situation and in circumstances congenial to it, it nearly approaches a floral wonder. Does equally well as bush, standard, or climber, and grows to a great size. I have seen a stem as big as a man's arm and defended by enormous thorns. It produces an abundance of flowers of good size and regularity. The English grower who is recommended to harden his heart when engaged in disbudding (hoping thereby to obtain a few fine flowers) would be astonished if he saw the *Duc de Magenta*, which has taken possession of an old Olive tree here, unpruned and never a flower-bud taken off. His Grace produces many scores of perfect flowers at the same time, any one of which would be good enough for show purposes.

"GENERAL SHABLEKINE.—A strong pink, shaded to brilliant copper, reverse of petals almost purple. Grows to a good size, very hardy and vigorous, eares neither for cold, or damp, or sun, nor is liable to mildew. If a law was passed that one man should cultivate but one variety of Rose, I should without hesitation choose *General Shablekine*; for general utility it is without rival, flowering continuously from October to summer, flowers of fine shape and wonderful evenness; a hundred blooms could be gathered off one plant, and every one exactly resembling its neighbour; the flower-stalk has a peculiar curve, which identifies it from other sorts. But little known in England, which is surprising, as its good constitution and hardiness would almost guarantee success in a colder and more gloomy climate. This of all Roses serves us most faithfully and generously.

"MME. MARIE LAVALLÉE.—Bright rose, shaded and lined with white, almost single, vigorous, and remarkable for its freedom of growth—a very beautiful and most graceful Rose, a general favourite with all who know it. Not a long-lived sort, the flowers from young plants being greatly superior to those of, say, four years or more. The petals are delicate and easily injured by wind or sun. Answers very well under glass.

"MME. CROMBEZ.—A pure yellow, good-sized flower, full, imbricated, with outside petals reflexed after the manner of *La France*. When well done this is the most beautiful of all Roses;

it seems to be capricious, hence not too popular among the growers; satisfactory for cutting, as it lives in perfect condition a long time in water. One of our greatest favourites.

—“**SYLPHIDE.**—Yellow flesh-colour, vigorous, grows to a big size, and sweet-scented. In bud or half-open stage no Rose in cultivation can excel it in beauty, shape, or delicacy. Filbert-shaped, with petals folded one on the other with remarkable regularity, the edges slightly recurved as in *La France*. Flourishes to great advantage under the protection of glass, its flowers being very delicate. Wind or rain or too much sun are detrimental to the perfect opening of its flowers. Beautiful foliage of the same shade as that of *Maréchal Niel*. Not a common Rose, but one well deserving more attention and notoriety. Unfortunately, a great favourite with the Rose bug.”

CHRYSANTHEMUM PAPERS.

THE French National Chrysanthemum Society has recently issued a reprint of the papers which were read last November at the Orleans Conference, and which originally appeared in the society's journal, *Le Chrysanthème*. The first of these papers is entitled “Diseases and Parasites of the Chrysanthemum,” by M. Chifflet, of Lyons. This gentleman describes the various insect pests and the diseases they cause, and the treatment necessary to deal successfully with them. A double-page illustration accompanies M. Chifflet's article, which treats of the insects in their proper classes, orders, genera, and families, while with regard to the vegetable parasites, remedies are given to enable the grower to combat them.

M. R. Gerard contributes a paper on “The Fertilisation of the Chrysanthemum,” which is also illustrated with figures explanatory of the process, whether of self-fertilisation or cross-fertilisation, the latter of which was not until recent years much understood or practised in England, but which seems to have long interested the French raisers of new Chrysanthemums.

The third and last of the series is from the pen of M. H. Fatzler, a well-known practical cultivator for exhibition, and one of the very first in France to demonstrate to the public the capabilities of the popular autumn flower. The subjects dealt with by this gentleman are the best manures and composts to be used in growing Chrysanthemums. After several observations on chemical subjects, and coming to the question of applying liquid manures, M. Fatzler says: “Do not forget this principle: The more vigorous a plant is, the more frequent should be the liquid manure waterings; but the slower the growth, the less frequent they should be.”

These papers form a neat little brochure of thirty-six pages, and are well printed and stitched in a paper cover. The price inclusive of postage is only a shilling, and to any grower interested in the subject, and capable of reading French sufficiently to master some of the technicalities, the work will be a useful addition to his bookshelf. M. Octave Doin, of Paris, is the publisher.

C. H. P.

A new Chrysanthemum catalogue.—M. O. de Meulenaere, of Ghent, who has already issued several descriptive catalogues of new Chrysanthemums, most of which have been briefly noticed in *THE GARDEN*, has just issued a third supplement, published under the auspices of the Royal Agricultural and Botanical Society of Ghent, which brings the previous works up to date. In style, form, and get up generally the present issue is uniform with the previous editions, but contains the novelties from all sources that have been distributed between the years 1896-98. In view of the approaching conference at Troyes, M. de Meulenaere in his preface points out several guiding rules for the cataloguing of the names of Chrysanthemums, and which is now being very generally adopted on the Continent.—C. H. P.

TREES AND SHRUBS.

THE MOUNTAIN LAUREL POISONOUS.

(*KALMIA LATIFOLIA.*)

DESCRIPTION AND HABITAT.—A fine shrub, usually 4 feet to 8 feet, but sometimes 30 feet to 40 feet high. It has thick, flat, and shining leaves, showy clusters of peculiarly shaped, viscid, and mostly inodorous pink flowers, which appear in May and June, and a globular, viscid, dry, and inedible fruit. It grows abundantly on rocky hillsides, in cattle ranges, and on mountain slopes up to 3000 feet or 4000 feet, from Connecticut to Eastern Ohio and along the Alleghenies to Georgia and Alabama; less abundantly in the New England and Southern States as far as Louisiana and Arkansas.

POISONOUS CONSTITUENT.—The active constituent, andromedotoxin (from the name of a closely related genus, *Andromeda*), is found in all parts of the plant with the exception of the wood. It is a peculiar crystalline substance, easily dissolved out of the plant by cold water or by alcohol. It is extremely poisonous, more so even than strychnine.

VICTIMS.—Scores of cattle and sheep are poisoned annually by eating the shrub. Access to it is generally obtained by breaking away from inclosures, or through neglect or accident when cattle or sheep are being driven past Laurel thickets to upland pastures in early spring. Laurel leaves (commonly used for decorative purposes in winter), or the flowering branches, are often carelessly thrown into inclosures where animals are kept. The older cattle are not so frequently killed by it, but they are by no means immune. Horses and even goats have died from eating the leaves, and in May, 1895, a monkey was killed at the National Zoological Park at Washington, D.C., by eating a few flowers and leaves offered to it by a visitor. Deer and grouse are said to be immune, and it is claimed that their flesh, especially that of the ruffed grouse, is poisonous when they have fed upon it. It is stated that chickens have been poisoned by eating the vomited matter from poisoned animals. Experiments show, however, that they are able to withstand considerable quantities of the pure poison when it is fed to them. In these experiments the chickens were killed with chloroform after dosing for a few days. The entrails were then cast aside, and the well-boiled meat was fed to cats with nearly fatal results. The honey derived from the nectar of the flower appears to be poisonous under some conditions. Cases of human poisoning occur indirectly in the ways indicated above; directly by overdoses, or improper use in domestic medicine, probably by the secret and criminal use of the leaves to increase the intoxicating effects of liquors, and, in children, by their eating the young shoots by mistake for the Wintergreen (*Gaultheria procumbens*).

SYMPTOMS AND ANTIDOTE.—The general symptoms in sheep may be taken as representative for those in cows and goats. They are as follows: Persistent nausea, with slight but long-continued vomiting and attempts to vomit, frothing at mouth, grating of teeth, irregular breathing, partial or complete loss of sight and feeling, dizziness, inability to stand, extreme drowsiness, coma, and death. The irregularity of the respiration is most characteristic, being present throughout the main part of the attack. In addition to most of the above effects there is, in man, severe pain in the head, an increased tendency to perspire, and often a peculiar tingling sensation in the skin throughout the entire body. Vomiting is very copiously pro-

duced, and consequently the effects are generally less severe than in animals. Respiratory stimulants, such as atropine and strychnine, should be given as antidotes by competent medical authorities. Oil, melted lard, or fat from bacon may be administered to animals by anyone with hopes of saving life, especially if offered when the symptoms are first noted. As a chemical antidote to be tried by physicians in cases of human poisoning, the writer suggests the internal use of a 1 per cent. alkaline solution of permanganate of potash.

The Broad-leaf Laurel is typical in its effects of a half dozen or more native species of the Heath family. They are all poisonous in the same way, because they all contain the same toxic substance, andromedotoxin. Many fatalities are recorded against the following:—

NARROW-LEAVED MOUNTAIN LAUREL.

(*KALMIA ANGUSTIFOLIA, L.*)

OTHER NAMES.—Sheep Laurel, Lambkill, Sheep Poison, Lamb Laurel, Dwarf Sheep Laurel, Small Laurel, Low Laurel, Dwarf Laurel, Wicky.

DESCRIPTION AND HABITAT.—Like the preceding, but smaller, only 2 feet to 4 feet high, with smaller, thinner, and narrower leaves, and smaller flowers, clustered not at the extreme end of the stem, but at the base of the fresh shoots. It is abundant at low altitudes in both dry and wet soils from Maine to New Jersey; less abundant westward throughout the Great Lakes region and southward to Tennessee and South Carolina.—V. K. CHESNUT, in “Poisonous Plants of United States.”

MAGNOLIA PARVIFLORA.

ANY addition to a genus of hardy trees and shrubs so beautiful and so striking as the *Magnolias* are is always a matter of interest. In the present case it is especially so, for, in spite of its unpromising name, *Magnolia parviflora* is a worthy member of the notable group of plants to which it belongs. Of this the illustration will afford sufficient evidence. The plant from which it was prepared was imported from Japan about five years ago, and is now growing on a sunny bank in the Bamboo garden at Kew. Whilst to us in England this *Magnolia* is a new plant, it is by no means new to botanists, for it was described by Siebold and Zuccarini as long ago as 1843. In the United States, too, where they seem to have been considerably ahead of us in the introduction of several fine Japanese trees and shrubs, it has been in cultivation for at least fifteen years. There is a picture made from a plant that flowered in Messrs. Parsons' nursery at Flushing, New York, in *THE GARDEN* for December 8, 1883. This, however, does not give an adequate idea of the beauty of the plant.

Magnolia parviflora cannot, of course, be compared in its general aspect at flowering time with the early *Magnolias* of the Yulan race, which in some respects are the most wonderful trees of the north temperate zone. But as it flowers long after they are past it is not brought into competition with them. This year it commenced to flower in May, and continued to produce its blossoms until July, although there were usually only some three or four flowers open at one time. But this particular plant is as yet small, only about 4 feet high. In the beauty of its individual flowers this species will bear comparison with any other. Indeed, with the exception of its near ally, *M. Watsoni*, it has the most beautiful flowers of all the *Magnolias*. They are each 3 inches to 4 inches in diameter, the six petals being very concave and

giving the whole flower a cup-like shape. On first opening the petals are of a beautifully pure

its distinctive beauty. At first erect, they ultimately spread out quite flat, forming a disc

vide a most effective contrast with the snowy whiteness of the petals. There are three sepals,

Magnolia parviflora. From a drawing by H. G. Moon.

white. As in *Magnolia Watsoni*, it is the central cluster of stamens that gives to the flower

are of a beautiful rosy crimson colour, and pro-

which are drooping and of a more creamy white than the petals. The flowers are charmingly

fragrant. This *Magnolia* gives every indication of thriving in our climate. It is of course quite hardy. The leaves are from 3 inches to 6 inches long, dark green and quite smooth on the upper surface, but pubescent beneath, more especially on the midrib and veins. The species has generally been looked upon as a native of Japan, all the plants in cultivation having been imported direct from there, but Professor Sargent, in his "Forest Flora of Japan," includes it among many other plants which he says are only cultivated in that country, and are really natives of China and Corea. W. J. BEAN.

Acer platanoides Schwedleri.—The young leaves of this Maple are red, and when first expanded they are very bright and effective, but they soon become green, and are then, of course, much less noticeable. Still, the growing points remain brightly coloured, and a tree of this variety is decidedly attractive when the mass of green leaves is lit up by numerous tufts of a reddish hue. This may often be seen during the summer if the season is not too dry to arrest growth altogether. Of course, a sunny spot is necessary to produce the brightest tints.—T.

Oxydendron arboreum.—This, which is also known by the generic names of *Andromeda* and *Lyonia*, is in some parts of the United States of quite tree-like dimensions, and under favourable conditions in this country it can almost be regarded as a tree, but still it will flower freely as a bush not more than 6 feet high, and, blooming as it does towards the end of August onward, it is all the more valuable. The flowers, which are borne in slender racemes at the ends of the branches, are white, urn-shaped, and of that wax-like nature common to many of its immediate allies. It is an old plant in gardens, having been introduced from North America in 1752, but is not often met with, owing probably to the fact that it frequently fails to grow in a satisfactory manner. A fairly cool, moist soil of a peaty nature and a not too exposed spot seem to suit it best. Apart from its blossoms, this shrub has also another strong claim to recognition, for in autumn the leaves change to a brilliant shining red colour, and they often remain in this stage some time before they drop.—T.

Bracken in the shrubberies.—In places where the wild Bracken grows freely a very pretty effect is secured by allowing it to grow up among *Rhododendrons* and other shrubs. At this time of year, after the flowers are over, it lights up the trees, and has a wonderfully pretty appearance. By far the prettiest bit of garden scenery I have seen lately was at Roughton Hall, Bury St. Edmunds. In an open part of the shrubbery, where grass walks have been laid and wide borders formed, a large corner has been planted with *Lilium longiflorum*, and the thousands of flowers now open, backed by the green of the *Rhododendron* and Fern, are really beautiful. Seen on one of the hottest days in August, the cool, refreshing green and the pure white Lily flowers were a sight not easily forgotten, and though, of course, both *Rhododendrons* and Bracken grow here like weeds, which they will not do in some places, it is worth trying to get such a lovely picture. In open positions and in some soils the Bracken takes on lovely autumn tints, and for this effect alone in the landscape it would be worth preserving or even planting where it does not grow naturally. It is, in fact, one of the most beautiful of wild plants, but so common as to pass almost unheeded.

Sambucus racemosa.—This, the scarlet-berried Elder, is far more particular in its requirements than our own native species, which it resembles to a very great extent, except that the berries when ripe are of a bright scarlet colour. It is a native of Central Europe and Siberia, and needs a cool, fairly moist soil, and only under conditions such as this is it seen at its best. When in a flourishing state, however, the brilliantly coloured berries yield a grand display at

the present time. Like the common Elder, the scarlet berried form is very variable in its leafage, there being many well-marked forms in cultivation. One of the most distinct and a strikingly ornamental shrub is *S. racemosa tenuifolia*, in which the segments of the leaf are so extremely narrow as to suggest one of the tropical *Arahas*, or a variety of the Japanese *Acer polymorphum*. It forms a very graceful bush, whose distinctive features are a great recommendation. Another variety which is, like the last, of comparatively recent introduction is a valuable addition to golden-leaved shrubs. This is *S. racemosa plumosa aurea*, in which the leaflets are so divided as to give them a plumose character, and in addition they are when first expanded of a soft yellowish green, which quickly deepens by exposure, as in the case of the golden form of the common Elder, which forms such a bright golden object in so many places. Where somewhat starved and fully exposed to the sun it acquires a richer colour than under any other conditions. There are several other foliage varieties of *S. racemosa*, such as *serratifolia*, *laciniata*, *ornata* and *pteridifolia*, but they are rather apt to outgrow some of their distinctive features when large. They can, as in the case of the common Elder, be readily propagated by means of cuttings, and, as above mentioned, the varieties *tenuifolia* and *plumosa aurea* are from a foliage point of view alone well worth attention.—T.

NOTES & QUESTIONS.—TREES & SHRUBS.

Coprosma acerosa.—This curious little shrub was at the recent show at the Dell Hall in Messrs. Veitch's group. The compact little bush is freely covered with miniature Goose-berry-like fruits, which are greenish blue and semi-transparent. It should prove of service in the rock garden.

Jasminum officinale grandiflorum.—This, which is now regarded as a variety of the common white Jessamine, was at one time looked upon as a distinct species, under the name of *Jasminum grandiflorum*. In this the flowers are larger, and tinged with red on the outside. The blossoms are deliciously scented. It is a good climber for a greenhouse, where it will flower for months together. It has also been in bloom for some time on the wall of the herbaceous ground at Kew.—T.

ROSE GARDEN.

MONTHLY ROSES.

FOR massing in long borders of sandy soil or filling large beds nothing can be more effective, lasting, or useful for cutting than monthly Roses. From the beginning of June till well into November they are covered with bloom, and if cut with long stems will make up delightful vases. In the hotter days of summer they will even last well, but it is during the autumn months that their durable qualities as cut flowers are most manifest. I have had them then in good condition for a week. The introductions of recent years give us now a variety of colours to select from, and if the new ones grow and flower as freely as the old pink one, most pleasing results can be obtained. In the gardens at Castle Howard, Yorks, there are two borders along one of the principal walks, and about 300 yards long, filled with the old pink. One half the length of the borders is of sandy loam, while the other half is heavy, inclined to clay. The Roses on the light, sandy formation grow luxuriantly and flower freely, while those on the heavy medium merely exist, proving that Roses of a twiggly habit should be given a light soil. Monthly Roses with a more vigorous constitution than the old pink should be the ones selected for heavy, tenacious soils. In the case of the borders at Castle Howard, the front row was planted 2 feet from the edge of the walk, and 18 inches from plant to plant.

The three rows were also 18 inches apart, planted alternately, and backed up with a row of Fellenberg, which formed a good screen to the vegetable ground behind it. Fellenberg is free-flowering, and frequently makes 4-foot growths, which are very useful for filling exceptionally large vases. Instead of the ordinary method of pruning adopted in the case of H.P.'s, the monthlies were clipped into a shape sloping from front to back, the front now being kept at about a foot high.

In the way of feeding I found nothing excelled farmyard liquid manure. This was liberally applied during the winter and early spring months, followed with a dressing of quicklime in early summer. The borders were never dug, only pointed about 2 inches deep, and all weeds kept down with the hoe. Under such treatment these monthly Rose borders presented a mass of colour for nearly six months every year, and were the admiration of thousands of people who saw them. Where a light soil obtains, and there are width and length of it at command, I would strongly recommend a portion being devoted to the cultivation of some of the varieties of monthly Roses with twiggly growths, and treated in the manner referred to in the foregoing remarks. If this be done, and either one variety or large groups of several be used, a very effective natural picture will be secured, and a useful source of cut flower supply be at command. J. RIDDELL.

Rose Madame Eugenie.—I have one plant of this against a wall. It would not bloom, but made all growth. This year I have kept stopping the strong shoots all through the summer when 6 inches to 12 inches long. I have had a lovely lot of blooms for the last month, and it is now full of bud. I can count over fifty buds this morning, and each shoot now forms a flower-bud, not growth.—J. M. HEWITT.

ORCHARD AND FRUIT GARDEN.

OVER-PRUNED FRUIT TREES.

ONLY those whose vocation leads them to make journeys in various parts of the country by road as well as by rail have any conception of the great numbers of over-pruned fruit trees there are in existence. Time after time the advice to be less free with the knife has appeared in these pages, apparently without any marked effect upon the majority of reckless pruners. If any good resulted from this misdirected zeal in the matter of pruning bush and pyramid trees there would be some excuse to offer, but according to my experience, the crop consists principally of dense thickets of young shoots, which effectually hide what few fruits there may be on the trees. In not a few cases the winter pruning is done with much the same exactitude as was pursued in the old days when topiary work was in great favour, but neat, mop-headed trees, or any heads of the same exact outline as a sugarloaf, are not particularly ornamental and of next to no value for producing good fruit in quantity. Owners of over-pruned trees can judge for themselves better now than at any other time of the condition of their trees, and be guided in their future treatment of them accordingly.

More rational methods of pruning ought to be initiated, starting now. Where the young shoots are so thick as to quite shut out the light and air from the inside of the trees, summer pruning should be practised, but not, as too often happens, to the extent of shortening severely every young growth on the tree. Instead thin them out very freely, spurring the shoots back to the fourth or fifth leaf. Reserve

all the more prominent growths or those at the extremities of the branches, or in positions where the tree would be improved by the addition of one or more branches, leaving them to their full length. Next winter all these reserved shoots should be left to their full length, shortening, however slightly, causing them to push forth wood growth at the extremities only; whereas if left intact the more natural distribution of sap leads to a break at nearly every joint, but in this case fruit buds, as so often pointed out, are the outcome. This growths formed this summer and left to their full length for another whole season will in most instances be wreathed with strong flowers in the spring of 1900. In the meantime, opening the trees to the beneficent effects of sunshine and air will most probably make them more fruitful on the older wood, this improvement being observable next season. Inexperienced fruit growers ought to bear in mind that the harder they prune, the stronger will be the growth of wood and but little fruit be obtained. Prune, then, for wood or to frame out a tree, and be as sparing of the knife as possible or in reason afterwards. One great hindrance to reform in the direction of pruning garden trees is the near proximity of many of them to walks, and the short distances apart at which others are planted. If the trees are large and comparatively old, moving them farther back from the walks would be both a laborious and risky proceeding. But what if the trees do overhang walks? Or, again, what if they are not quite perfect in form owing to the necessity for shortening a few overhanging shoots? Where the trees are in plantations and likely to be too thick if allowed to develop naturally, I would unhesitatingly sacrifice a few of them, knowing that by so doing those reserved would produce far more fruit than double the number of badly pruned trees had previously done. W. GARDNER.

Barker's Seedling Apple.—This variety, which seems to be also known as D. T. Fish and Cobbett's Fall Pippin, is really a robust form of Warner's King. I have seen it at Maiden Erleigh for several years past, and although Warner's King is grown there under similar conditions, Barker's Seedling is the better grower, best and most reliable cropper. The soil at Maiden Erleigh is stiff clay and not at all of the best description for Apples, but no tree could be healthier than is the one named. It has been remarked that the season seems favourable to Warner's King, but so much depends in trees on how well they cropped last year. Generally the best crops of the season are found on trees that bore indifferently last year.—A. D.

Perpetual Strawberries.—The paper M. Vilmorin read at the Royal Horticultural Society's meeting on Tuesday should receive wide publicity when it is published in the Royal Horticultural Society's journal, and possibly it may in that way give material stimulus to the cultivation of the "perpetual" strain. But the term thus used is rather a misnomer, as it leads to the assumption that the varieties referred to are both perpetual bearers and growers. In this country it is unlikely that the fruiting season would be longer than from June to October, both inclusive. But it seems to be a fact that if the plants be relieved of the first bloom, then they fruit all the more freely later. That practice, I believe, prevails somewhat at Gunnedersbury House, where Mr. Hudson so successfully grows alpine strawberries from seed and gets a long season in the way mentioned. The general character of all the perpetual fruits shown the other day was small size, soft flesh, and absence of flavour. It was but needful to taste the nice fruits of Royal Sovereign, a second crop, sent by Mr. Hudson, and not, of course, equal to what the variety produces in its

proper season, to realise what a gulf there was in quality and flavour between the superb varieties we have become accustomed to and the best of the alpine or perpetuals. The variety shown by Mr. Laxton bore exact resemblance to the French St. Joseph in its habit of sending up bloom-trusses from runners.—A. D.

APPLE BLENHEIM ORANGE.

PROBABLY no Apple is so popular all round from the consumer's point of view as the Blenheim Orange. It is a large and handsome fruit of good quality and texture, and may be used either for cooking or for dessert about Christmas and new year's-tide, a period of the year when Apples are in great request. According to the Royal Horticultural Society's classification it is to be known as a dessert Apple, and with this I entirely agree, although full-grown

Apple Blenheim Orange. From a photograph sent by Mr. J. C. Tallack, Livermore Park, Bury St. Edmunds.

specimens are much beyond the size generally considered best for the dessert, but its very handsome proportions and appearance command admiration, and its flavour is very pleasant if not over-piquant. As a cooking Apple, except for baking whole, it seems to me to lack acidity, though this very fact commends it to many connoisseurs. From the grower's point of view it is not always satisfactory, for the tree, except when in bush form on the Paradise stock, takes many years to come into bearing, and even when it has commenced to bear it is by no means certain. As a close-pruned garden tree it is one of the worst of bearers, and in this form it is useless to plant it, because its nature of growth and fruit bud formation make it imperative that to produce crops of fruit it shall be allowed freedom of growth. The most

satisfactory trees are those planted in cultivated orchards where they are allowed to spread themselves without limit in bush form and pruned simply to keep the branches thin. The tree when on the free stock requires a great amount of head room. The best and most fruitful trees under my charge have heads with a diameter of over 30 feet, and still spreading. They are kept thin as to branches, many of which are at the present time borne down to the ground with the weight of fruit. Trees of half the size and spread are growing on the Paradise stock and are equally fruitful, but under orchard culture the fruits are not so fine, though still large enough for dessert. Medium-sized Blenheims, such as these trees bear, are much in request. In some orchards the Blenheim cankers badly, but this is generally when the soil has been over-manned at planting time, or in cases where the soil is cold, wet, and undrained. In my own case I apply no manure of any kind to the soil when planting, but rely entirely on top-feeding with wood ashes, gas-lime, and stable manure in a decayed state; the latter would not be used if the staple soil were heavier, but, being very light and sandy, the trees require extra support. The orchard being on grass land and the grasses mostly coarse, I have the coarsest tussocks grubbed out round the trees every winter as far as the feeding roots spread, not confining the process to a very limited area just round the stems, and apply the top-dressing in spring, adding a further mulch of long stable litter to the surface if thought requisite, which is, however, but seldom the case with the Blenheim on the free stock. Those who are not prepared to allow the trees plenty of head room had better leave this Apple out of their calculations when planting.

Like many other popular Apples, it is claimed for the Blenheim that there is more than one variety of it, and attempts have been made to describe them, but, as far as my experience goes, these so-called varieties of the Apple have turned out to be some totally distinct and generally inferior variety, though in some cases stock influences have contributed to a slight change of form or colouring. J. C. TALLACK.

Apple Langley Beauty.—This excellent new early Apple, shown so recently by Messrs. Jas. Veitch and Sons at the Drill Hall, and to which an award of merit was granted, is the product of one of Mr. Seden's crosses made in 1896, and so far has been the first to fruit. As a seedling it fruited early, and so much was it liked, that it was worked by budding, in the autumn of 1896, on the Paradise stock, several buds being inserted. This season, the second from the bud, each tree has carried fruits, showing that it is precocious as well as productive. The fruits have soft, pleasant white flesh, like one of the parents—Mr. Gladstone—but the other parent has somewhat imparted its flavour, as might be expected from so admirable a variety as Cox's Orange Pippin. The fruits colour moderately and have un-

doubted characteristics of both parents externally. As it ripens fully in the middle of August, it bids fair to become a popular market variety.—A. D.

MILDEW ON VINES.

I WILL feel greatly obliged to the editor of THE GARDEN by his informing me what I had better do with my Vines (ten in number), which have been attacked by mildew for the last three seasons, and which previously had been in fine bearing for many years. Last year about 200 bunches were cut down and burned with the rubbish. This year there are very few Grapes, and those are worthless, being covered with the dirty white dust and not able to swell at all. The foliage is not so much infested as usual. Will it be necessary to cut down and root up all the Vines and burn them, or can any remedy be applied instead?—J. H. F.

* * Eradicating mildew from a vinery is not an easy matter, but it can be accomplished, and that, too, without the loss of a crop and at a comparatively trifling cost. The alternative suggested by "J. H. F.," viz., cutting down and rooting out the old Vines and starting afresh, might perhaps be the best in the end, but would prove laborious and costly. If the Vines are old, and in particular the borders have long since been exhausted, then it would be well to clear out both the Vines and the borders, doing this during the autumn and winter and planting young canes, say about March next year. As the letter conveys no information as to the age of Vines and borders, I cannot express an opinion upon the wisdom or otherwise of longer preserving them. I will, however, advise upon combating the mildew, and it can then be decided on the spot which line of treatment will best meet the case. Flowers of sulphur is the simplest, safest, and most effective remedy for mildew. Every leaf infested by the disease should be well coated with sulphur, doing this early in the morning or while yet the upper surface of the leaves is damp. In this extreme case, and in all other instances where the mildew has got the upper hand, the stems, laterals, and every leaf and bunch should be dusted freely with the sulphur. Sulphur will slightly disfigure the skins of white or yellow Grapes, but has no ill effect on the thicker-skinned black varieties, and when the bunches are cut all that is necessary to make them presentable is hold them a minute or so under a good pressure of clear water. The sulphur sticks to mildewed berries, but these would have been worthless in any case, the water cleaning the sound berries without injuring the bloom. Mildewed Vines ought to be further kept well supplied with moisture at the roots, and everything done to favour the growth of roots and the maturation of good fruiting wood for the following season. All leaves, prunings, and rubbish generally should, early in the winter, be cleared out and burnt, the woodwork either painted or thoroughly cleansed, the glass also washed, and the walls dressed with thin hot lime water, every possible lurking place of mildew germs being visited in turn. So potent are these disease germs, that a thorough cleansing of the house would be necessary even if it were decided to start afresh with a new border and young Vines. Hard pruning should not be resorted to if there is any doubt about the Vines producing plenty of bunches in the spring. Shorten to the second bud from the rod rather than study neatness at the risk of a light crop. After pruning, clear the rods of all loose bark, but avoid severe scraping, and then well dress them with Gishurst compound at the strength recommended on the box, and to which a handful of flowers of sulphur may be added with advantage. A very thick dressing formed by the addition of too much clay is not desirable, as only a thin dressing can be properly brushed into every crevice. After this work has been done, the border, if inside, should be taken in hand. Fork away and wheel out the surface soil down to the roots, well baring the uppermost layers of these, and then top-dress with a mode-

ately rich compost, one-half of which may be fresh loam and the rest made up of partially decayed horse-droppings, fine mortar rubbish, charred soil and wood ashes, and a good sprinkling of bone-meal. It is just possible inside borders may be found much too dry, in which case a thorough soaking of water, or, better still, liquid manure, should be applied after the roots are bared, and a few hours prior to top dressing. Many old inside borders would be improved by this treatment even if the Vines are not infested by mildew. Where the roots are in an outside border and this has not been top-dressed recently, treat as advised in the case of inside borders, only deferring this important work till March or April. In May mulch either inside or outside borders with strawy manure and see that they never become very dry.

Not only have I done all just foreshadowed, but I have also generated sulphur fumes in a vinery while yet the mildew-infested Vines were at rest or leafless, and yet not succeeded in wholly getting rid of the disease. Those, therefore, who may follow the instructions I have so far given must not be certain of success at the first attempt. After the Vines are re-started into growth the ventilation ought to be attended to. No front air should be admitted much before the middle of May, and not then if easterly winds prevail, as currents of cold air playing on the tender leaves are very apt to start mildew. A close look-out should be kept for any traces of disease, and every spot of it seen be heavily coated with sulphur. It sometimes happens that the first signs of it are observable in the bunches soon after the berries are set. Very carefully remove every affected berry, and if necessary to prevent a further spread, heavily dust the bunches with flowers of sulphur. In this determined manner mildew ought to be stamped out without any further loss of crops.—W. IGGULDEN.

SUMMER PRUNING OF PEACHES AND NECTARINES.

MANY trees this season have not borne a heavy crop owing to the severe weather when the trees were in bloom, and with trees in such a condition the wood growth will be much stronger. It is not wise to encourage too much wood, thinking another season will set matters right and a heavy crop may be taken. Far better get the wood laid in thin. Many do not wait till all the fruit has been cleared before laying in new shoots, as these, if left loose, twist about and get broken. It often happens that one can freely extend young trees; indeed, old ones, if there is wall space, will take a fresh lease of life. With low walls extension is not an easy matter, but by doing the pruning as soon as the fruits are cleared anyone can often assist trees in the position described by taking out poor branches from the base and laying in new vigorous wood. I have found that trees attended to at this season, removing old fruiting wood and any other that is not needed, are much better fruiters than those hard pruned in winter. More small or twiggy wood is needed with some of the American kinds, and I notice some are not strong growers here. One must not be too severe in pruning. On the other hand, I would advise giving the trees more space to allow the wood to ripen, as unless this is done the crop is poor, as the wood of American kinds needs more ripening than that of our own kinds. By giving the newly-made wood room the older foliage will not suffer. This if crowded is at times attacked by red spider, and the buds needed for next year suffer badly; indeed, they are so much weakened that they affect the fruit the next season. I have noted the importance of extension wherever it can be followed out, and on high walls there is plenty of space to do this. It can be done yearly there will be no trouble with canker, as the Peach and Nectarine delight in free extension. It is the hard cutting back of trees in a young state that does so much mischief. Take young trees. What splendid growth these

will make in a season if given free play, and, once the tree is shaped, I fail to see the necessity of such hard cutting back, as I never found any difficulty in getting the base furnished if the tree was regulated at the start. I do not mean that all the wood made should be laid in, but I certainly would hesitate to cut hard back good wood. Far better get fruit from it another year to check growth. By pruning now the trees are much benefited, as the buds swell up and are exposed. In a dry season with a lot of useless wood there is a great demand on the roots, and this should be avoided. G. WYTHES.

MANURING FRUIT TREES.

OUR fruit trees take a certain amount of plant food from the soil, which, if not returned to it in some form or other, will ultimately result in failure or inferior crops. Much, however, depends on the natural fertility of the land, as some formations are rich in all the constituents of plants in an available condition, while others are not, so that the number of years the soil will maintain a healthy growth will depend on its composition. The trees themselves will form the best guide as to requirements. Weak, wiry growth may be taken as an indication of a want of nitrogen; small flowers and fruits and soft wood, a lack of phosphorus; and bad colour in flowers and fruits and a disinclination to branch as a deficiency of potash. Of course, the conditions of growth, flowers and fruits are considerably influenced by seasons, moist ones favouring sappy wood, and hot, dry ones wood of a small and wiry character. There are many kinds of manures which we have to select from to supply any deficiency in the soil; our aim ought, nevertheless, to be the selection of the most economical, all things considered. By mentioning the most economical it might be inferred that the cheapest constituted such. This might and might not be the case. Basic slag is certainly the cheapest form in which phosphorus is obtainable, and decidedly the one to use on heavy soils rich in humus. But on sandy formations deficient in organic matter it would be simply time and money thrown away to apply it. The best phosphatic manure for a light sterile medium like this would be finely ground bone-meal, or this mixed with half its weight of superphosphate, either mineral or bone. These can be applied as they are, or incorporated with well-decomposed farmyard manure, when their solubility will be improved. Kainit is our cheapest source of potash, but the amount of common salt it contains renders it objectionable at certain seasons. If applied in autumn to early winter, when active growth in the trees ceases, there is time for the waterings essential during the dormant period to carry off the obnoxious ingredients. At any other time only a very limited quantity— $1\frac{1}{2}$ ozs. to the square yard—should be employed. Instead of utilising kainit to supply potash to growing crops, sulphate of potash would be a more desirable manure, and not by any means what would be termed expensive. In $1\frac{1}{2}$ ozs. of this to the square yard there is no useless inimical constituent to be reckoned with. Ashes from the burned refuse heap are preferable to either, but they are not always available in sufficient quantity, and carbonate of potash and nitrate of potash are much too expensive for general use in fruit culture. Compounds rich in nitrogen are all expensive. To cause a temporary increase of vital energy, such as is necessary at the stoning period of fruits, or to finish a crop, nothing can be better than nitrate of soda. When a nitrogenous manure is necessary, and to have lasting properties as well as to give immediate results,

nitrate of soda mixed with sulphate of ammonia in equal parts, and applied at the rate of 1½ ozs. to the square yard, is the one to use while the roots are active. For winter and early spring, sulphate of ammonia alone is best, and can then be used up to a strength of 3 ozs. per square yard. The soil having an affinity for this chemical compound, it is not readily washed away like nitrate of soda. Rape dust is another valuable nitrogenous manure for out-of-door work. It, however, takes a considerable time to arrive at its serviceable stage, and should be mixed with a quantity of well-rotted organic matter to facilitate its decomposition, and then forked into the land. Treated in this manner, rape dust generates heat within the soil, and promotes healthy growth for years once its fertilising properties come into play. The best general manure for fruit crops is undoubtedly the drainings from the cow byre and farmyard manure heap. It can be employed to assist growth in the summer months and to enrich the soil in winter. The latter period is, nevertheless, the best time to apply this liquid manure, there being no sensitive root hairs then to demand consideration or to interfere with a liberal dressing. In fact, both for out and indoor work the dormant period is the proper time to provide a sufficient supply of plant food to meet the demands of crops grown upon it for twelve months at the least. The only thing to guard against is an excess of nitrogen. This element can be supplied at will, as already shown, and growth regulated by a discriminate use of it. Fertilisers can be employed with safety and in a much more concentrated form during the winter months than can be done when the trees are in an active state of growth. I have used farmyard liquid manure in an undiluted state to the borders of Vines, Peaches, and Figs indoors, and to the soil surrounding the roots of Pears, Plums, Apples, Apricots, Cherries, Gooseberries, Currants, and Raspberries out of doors, with marked success. This liquid manure, too, aids in dissolving the basic slag. Its only drawback is the tendency it has to form acid substances in the soil, but this can be overcome by a free use of lime in the growing season. For indoors, three applications of air-slaked lime will be ample to keep the borders sweet if immediately washed in after being put on. For outdoor fruit culture, including grass orchards, I have found one dressing of lime sufficient to maintain the soil in a desirable condition for fostering a healthy, fruitful growth in the trees and bushes that were heavily fed with farmyard liquid manure.

J. RIDDELL.

The Strawberry Raspberry.—As Professor Bailey, of America, has pronounced this plant, thus misleadingly named, to be *Rubus palmatus*, it is to be hoped that we shall hear no more of the above title. When previously presented to the fruit committee much doubt was expressed as to its being a hybrid fruit at all. It now proves to be a real species. The chief uses of this *Rubus*—why named *palmatus* it is hard to understand—would seem to be, if grown and fruited in pots, to make decorative material for the sideboard, where its fine red fruits may thus prove effective.—A. D.

Apples at Rougham Hall.—A choice and varied collection of Apples and other fruits has been planted here, and there is a very interesting lot of fruit already. One of the best-flavoured and freest-bearing of the earlier dessert kinds is Mr. Gladstone, a nice-looking Apple of sweet, juicy texture and handsome appearance. The best fruit is on small trees planted two years ago as maidens, and as one of the most useful kinds, coming in before Janeating and Devon-hire Quarrenden, it should be freely planted. Of the latter, too, there are nice fruits and of the charac-

teristic bright red tint. That useful Apple Duchess of Oldenburg is well represented by fine fruit, but not quite so well coloured as yet as I should have expected. Doubtless it will be brighter as the season advances. I noticed some beautiful fruits of The Queen coming on, large, flattish round Apples already over a foot in circumference, while Tower of Glamis, Yorkshire Beauty, Peasgood's Nonsuch and others of this showy class are excellently represented. Coming to the choicer dessert kinds, Cox's Orange, Robston and Fearn's Pippins are carrying full crops of fine fruit, while American Mother is already handsome.—H. R.

KITCHEN GARDEN.

WINTER TURNIPS.

At this season those who need the best quality Turnips in winter will need to prepare the soil. The latter end of August and the early part of September are good times to sow for winter supplies. Owing to drought, I have been obliged this year to draw rather deeper drills than usual. These I flood previous to sowing and do not make the surface quite level when covering the seed. This allows of future waterings going direct to the seedlings and not running away, as if the soil is light and the surface is quite flat it is difficult to retain moisture. In dry weather the Turnip fly attacks the young plants, but this may be got over by watering overhead with a rose water-pot rather late in the day and giving a light dressing of sulphur and soot after watering. With tender seedlings the dressing must be a light one, and it will be better to repeat the dose than use too much at a time. The Turnip in winter is not always looked upon favourably, but in a measure it is the fault of the grower, as seeds sown at midsummer or even in July will produce coarse roots that do not keep, and are not even good for flavouring. These are the roots that are not liked. There is no difficulty whatever in getting good produce by sowing more frequently and by studying variety. An open position is best. I have found roots in the open much superior to those in sheltered borders. My winter roots are sown on land that has had a crop of early Potatoes. A heavy dressing of manure is not needed: indeed, I omit annual manuring, and give the land a dressing of soot and a good fertiliser, this promoting a quick growth. Size is not needed, as roots the size of a cricket ball are large enough for storing. In heavy land, manure from forcing pits, spent Mushroom manure, and burnt refuse may be used as a surface-dressing, and if the soil is at all poor it is an easy matter to give food on the surface during growth in the shape of nitrates or any other quick-acting fertiliser. Allow ample space between the rows, 18 inches being none too much.

As regards varieties, there is no lack of winter kinds. I would like to see more of the yellow-fleshed kinds grown for the season named, as these are the best keepers. In the north excellent Turnips may be had well into the spring. Golden Ball is one of the best. This is a very shapely root, and being very solid is a splendid keeper and of the best possible flavour. In my opinion it is superior in quality for use from December to April to the white-fleshed kinds so largely grown in this part of the country. I am not in favour of the flat section of Turnips for winter. Golden Ball, Orange Jelly, and others under diverse names are the best. Those who grow for the green tops in the spring will do well to study keeping properties, as though most kinds keep fairly well if sown

late in hard winters, there is a greater loss among the flat section. The purple-top varieties come next to the Yellow Globe, and Red Globe is difficult to beat as regards quality. This is largely grown in the south and is one of the best for winter, and sown now is just the size for storing. In warm soils and sheltered positions I would defer sowing till the early part of September, as with cool, moist nights growth is rapid once the plants have got through the initial stages. Red Globe keeps well in the store if not grown coarse. There never need be any hurry in storing; indeed, many do not store at all. Many market growers like the green-top kinds for winter supplies, but they are inclined to grow coarse in good garden soil. For many years the Chirk Castle was considered the best winter Turnip, but the quality of the Golden Ball section is so superior, that it is now much less grown.

I never put my roots under cover—I mean in a building—and I very much question if many roots are not spoiled by premature lifting. Far better sow specially for winter supplies, and store as late as possible in the open by putting in heaps if the weather be severe. For years I have found that drawing earth up over the roots in the rows where growing gives enough protection, and in the early spring when the tops begin to grow the roots may be pulled and placed in heaps under trees or a cool shed and covered over. If the soil is heavy I have drawn a couple of rows and got more earth for covering, but whatever shelter is given should be as simple as possible, as warmth starts the roots into growth and the flavour is spoiled. I prefer to leave a goodly portion of the roots in their growing quarters, covering these in severe weather with litter.

G. WYTHES.

Scarcity of good Cauliflowers.—The dry, hot weather has told upon the above vegetable, and in light, porous sorts it has been a delicate matter to keep the plants free of caterpillars, which so soon disfigure the heads. For years I have grown The Pearl for summer cutting, and it appears to stand heat and drought better than many others. It is not unlike Walcheren in build, but has a shorter stem, the leaves rather spreading. This is an advantage in seasons of drought, as the plant is protected. I find by growing between rows of tall Peas that the plants suffer less and give a good return. Though we are in the midst of the best season for vegetables there is none too much variety, and some kinds are none too plentiful owing to drought, so that the Cauliflowers come in most acceptable.—S. H. B.

Autumn Spinach.—In gardens in the early autumn Spinach often makes a gross growth at the start, and other vegetables being plentiful the growths are left undisturbed, with the result that the plants get very thick, and at the first touch of winter are liable to suffer. In market gardens plants suffer less, as they are grown more hardily from the start. This is a great gain with winter produce of any kind, as the plants in rich garden soil make such soft growth that they suffer badly. This may in a measure be prevented by severe thinning at the start, by allowing more space between the rows when sowing, and omitting large quantities of animal manures. I am aware manures are advised, but for any plant to stand over the winter much better results follow feeding from the surface early in the year just as new growth commences. I would advise early thinning when the plant is in a small state, as if left too late thinning loosens these plants left in the soil.—G. WYTHES.

Cardoons and drought.—The Cardoon is not a great favourite in many gardens, and doubtless this is owing to the small amount of favour it receives in the kitchen. I do not

advise the culture of Cardoons in any garden with a scarcity of water and of labour to apply the same, as unless there is ample attention in the way of food and moisture, the plants will bolt and are worthless. I admit they will produce an inferior kind of Globe Artichoke, but so poor that they are not worth cooking. Anyone who can give a regular system of irrigation can grow this vegetable well, but if the roots are at all dry there will be a poor return. It is surprising what large quantities of food and moisture these plants need, and in poor light soil or soil resting on gravel it is a difficult matter to prevent running in such a season as this. To be on the safe side I would advise sowing later and giving as cool quarters as possible.—G. W. S.

Dwarf French Beans and red spider.—This season has been one of the worst I have ever experienced for red spider in our light soil resting on gravel. It will be impossible to finish the crop unless more attention is paid the plants in the way of moisture and food, this adding greatly to labour. If moisture is given during the early part of the day it is lost in a few hours, and unless the plants are mulched between the rows I fear the crop will be poor and not of the best quality. Much may be done to keep the plants growing by damping overhead at night. If the foliage can be thoroughly damped over it will keep the plants growing, provided the pods are cleared regularly and not allowed to form seed. Early in the summer the plants made slow progress, owing to the cold winds and late frosts, and the cultivator had a difficulty in keeping them alive. The season as regards fruit and vegetables has been one of the most trying I have ever known. With August well advanced one does not often have to report severe attacks of red spider, as with cooler nights it does not spread.—S. M.

CUCUMBERS IN WINTER IN POTS.

It is not an easy matter to have a supply of Cucumbers from December to March. For many years I have grown winter Cucumbers, and I find pot plants more reliable than those planted out. I am aware that a greater weight of fruit may be cut from the plants in borders. I rely upon two lots of plants for the winter supply, sowing at this date (the latter part of August) or in September, and have one set of plants in pots. The other set is planted out in a small house. From these I cut very freely as soon as they can be fruited, and save those in pots for the latest supply. Many may think it unnecessary to have two sets of plants. I was of the same opinion till I had so many failures. There was no difficulty in getting a full crop of fruit well up to Christmas, but then the plants failed, and in a sunless, foggy atmosphere do not make the necessary new growths to produce fruits, and the root growth ceases if a goodly quantity of fruit has been cut in the earlier part of the winter. It is surprising what a quantity of fruit may be had from a plant in a small pot. Mine do not exceed 12 inches, and at the start the pots are only three parts filled with soil, made rather firmer than is usually done for Cucumbers. The pots stand on a slate bed, but are not plunged, and a rather low temperature is given from the start. This allows of a more liberal one when the plants are needed to fruit freely; on the other hand, there is no starving, and food is given in the form of liquid manure and soot water. From the early part of November close stopping is carried out. As long as new wood is made there will be fruit, and when the plants are allowed to bear it is essential to fruit sparingly. The advantages of pot culture over beds consist in a better means of feeding during growth, and getting a more fruitful growth and of a sturdier nature. Feeding from the surface is an easy matter, as I build up turf round the sides of the pots for the new roots to run into. Plants treated thus do not need much food when first potted. I sow in small pots, at the same time placing the larger ones in position to allow the soil to be warmed through. The plants are put out early, and, being close to the glass, grow

sturdy. The soil given is fibrous loam, with a liberal portion of wood ashes, or, failing the latter, some fine old mortar rubble, with a small quantity of bone-meal. When fruits show in the early part of the plant's growth they are removed.

G. WYTHES.

WINTER ENDIVE.

THERE is no difficulty in having plenty of Endive from September to December, but a good supply from the last-named date to the end of March is even more valuable. It is useless to sow Endive unless the position where wintered is a sheltered one, and even then at times the plants will not stand unless given glass protection. Those who have fruit cases or cold frames are fortunate, as here they may winter the plants safely. I find that provided the heavy rainfall is guarded against there is less trouble, as I find Endive much harder than Lettuce, and if in a green state, not blanched, it is surprising what severe weather a good type of round-leaved Batavian will stand.

In the southern parts of the country I have sown the first week in September, and even later. Farther north it may be advisable to sow in August. Thin sowing at this date is important, as it is essential to get a sturdy plant. Generous treatment will give a better plant. The seed-bed should be well worked and given plenty of manure. The same remark applies to the quarter for planting out in, as the season of growth now is a short one. In sowing for winter I give plenty of space, as it is not unlikely that a portion of the plants may be left in the seed-bed. These will turn in much earlier than those transplanted. Even without lifting and housing under glass I have had the Batavian good well into April by covering with dry Bracken and protecting with boards. Our winters are so changeable that anyone who can lift at the end of October will find it much the best plan. In doing this the smaller plants should not be despised, as these will give the latest supply. Large plants, or those at all blanched, do not keep so well, and if wintered in the open this should be borne in mind. Many prefer the fine green curled variety, but unless glass protection can be given it is not hardy. The Moss curled is the tenderest of all. I have found that in lifting the more care that is taken to get a good ball of earth and roots the better. In transplanting for winter supplies it is well to move the seedlings before they get large, doing this in dull weather. G. W.

Celeriac.—The plants will now be bulbing freely and will need ample supplies of water. Should the plants be dry at the root at this the critical period of their growth, they will fail to swell and the roots will be split, thus spoiling the shape and often causing a hardness that boiling fails to remove. The root must be succulent, and I would advise mulching between the rows in hot, dry seasons if the soil is light, and then, if copious supplies of liquid can be given, there will be fine roots of the best quality. Later roots will also need liberal culture, as these should be kept growing as long as possible. These will give a good supply well into the new year; indeed, till the end of March. The plants should never be dry at the root from the time of planting, as when stored in dry soil or in a room they shrivel badly, this affecting the flavour.—S. B.

Potatoes in light soil.—For some years I have noticed that those who plant such as the Ashleaf, Shurpe's Victor, and similar kinds as regards habit and crop suffer badly in such seasons as we have just experienced, as, owing to their shallow rooting, they have not sufficient strength to withstand drought. I am aware that light soil early in the season is most advantageous, as it favours earliness. On the other hand, if quantities are grown for later supplies it may be well to study the soil, as in a hot, dry season and with a very light soil the crop is not the most profitable, and it well repays the cultivator to grow

more robust varieties. The market grower depends largely upon those of the early Puritan or Rose type with a light soil, and gets a good return. If these are not liked (but they are of fine quality in dry seasons), there are such excellent kinds as Windsor Castle, Epicure, Ninety-fold, and others of the same type. These have more vigour, and consequently are more profitable in such seasons. In small gardens a great quantity of the larger growers now find favour, as the return is so much greater and the quality is not at all bad.—S. M.

Onions.—Although there has been a good deal of bolting out to flower on the part of winter, or rather autumn-sown Onions, yet have I found them to be almost everywhere wonderfully fine. This has been the case also from all sorts of soils—clay, loam, sand and chalk; but the finest, perhaps, come from stiff rather than light soils. The very finest to be seen anywhere—and I have during the past month seen hundreds of beds—was on stiff land in an allotment at Epsom, the variety being Ailsa Craig. These should continue to grow larger still, even after the Tripolis were pulled out over. All these winter Onions are grown wonderfully well in cottage gardens and on allotments, but they soon become useless after being ripe. Good white Spanish or Globe Onions are much better for the purpose. Spring-sown Onions are first rate generally, but many neglect to thin them early and properly. They are rather later than usual, but in myriads of cases the bulb crop will, relative to the dimensions of the breadth, be a very heavy one. In Onion culture gardeners must not assume that they are invincible, for in cottage plots one often meets with surprisingly fine beds. Maggot has given very little trouble this season. I have not seen a bad bed anywhere. Now and then mildew has attacked the plants, and it is doubtful whether any application short of the Bordeaux mixture would do the plants much service. Now and then a few of the old underground or Potato Onion is seen, some persons liking their flavour. The large red Jersey or sometimes called Russian Shallot seems to have materially displaced the true old Shallot in gardens. Cottagers and allotment holders grow these bulbs universally, and wonderfully well, too. When a good clean stock of the true Shallot is seen the bulbs are always to be preferred to those of the coarser strain.—A. D.

GARDEN FLORA.

PLATE 1186.

HIMALAYAN RHODODENDRONS HARDY NEAR LONDON.

(WITH A COLOURED PLATE OF R. CAMPYLO-CARPUM.*)

THE climate of these islands, whilst it has many drawbacks from the gardener's point of view, presents at least this advantage: it admits of the cultivation of a greater variety of ornamental evergreen trees and shrubs than can be grown anywhere else in the same degrees of latitude, or even with the same mean temperature, either in Europe or America. Evergreens as a whole may be said to thrive best where there is a continual moistness in the atmosphere and an absence of any great extremes of heat and cold. These conditions are pretty general in the southern parts of the kingdom and near the coast even well to the north, but it is in the south-west of England, S. Wales, and in Ireland that they are most marked and constant. In these districts most of the Rhododendrons natives of the Himalaya succeed wonderfully well—better, perhaps, than any-

* DRAWN FOR THE GARDEN by the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Godart.
